freeze-stop to stop a reaction rapidly by freezing the reaction mixture; to **freeze-clamp**.

freeze-thaw to disrupt cells in a suspension, or to disperse emulsions, by repeated freezing and thawing.

freezing 1 the change of a liquid into a solid by a lowering of temperature. **2** the stopping of a reaction or other process at a particular point, often by a lowering of temperature. **3** or **cryopreservation** the use of temperatures below 0°C in order to preserve biochemicals and foodstuffs, or to maintain viable populations of (micro)organisms.

freezing-microtome a microtome in which the tissue sample is frozen and maintained in a frozen state with liquid carbon dioxide. It is useful for (rapidly) obtaining sections of unfixed soft tissue. *Compare* cryomicrotome.

freezing point the temperature at which freezing (def. 1) occurs.

French chalk *see* talc.

French pressure cell a device to disrupt chloroplasts and bacteria, yeasts, or other cells. A cell or chloroplast suspension is placed in a cylinder fitted with a piston and a narrow outlet controlled by a needle valve. After removal of air, the piston is forced into the cylinder with a hydraulic press to the desired operating pressure (<20000 pound-force per square inch, 140 MPa). The valve is then opened. Extrusion through the narrow orifice together with the sudden release of pressure creates shear forces that break the suspended particles. *See also* **Hughes press**. [After Charles Stacy French (1907–), US plant physiologist.]

Freon the proprietary name for any of a group of fluorocarbon or chlorofluorocarbon compounds that are clear, colourless liquids, chemically inert, and of low toxicity. They are useful as refrigerants, aerosol propellants, cleaning fluids, and solvents. These substances have been shown to be important in the chemical removal of ozone by chlorine-catalysed cycles in the polar region during winter and spring. Nitric oxide and ice-clouds are formed in the polar stratosphere during winter. Heterogeneous chemical reactions take place on the surface of these particles, dramatically shifting the balance between inactive and active forms of chlorine and increasing the efficiency of chlorine in catalytic ozone removal. The use of Freon is being phased out in many countries; it is being replaced by substances such as tetrafluoroethane (ICI Trademark KLEA) which are claimed not to cause depletion of ozone.

frequency *symbol*: ν or f ; the number of complete cycles of any periodic process occurring in unit time. The SI derived unit of frequency is the **hertz**. The frequency of a wave is equal to its velocity divided by its wavelength.

frequency distribution a table, graph, or histogram constructed from a series of measurements to show the classes into which the measurements are divided and the numbers in each of these classes.

fresnel a non-SI unit of frequency of electromagnetic radiation, equal to 10^{12} Hz.

Fresnel diffraction the diffraction occurring when electromagnetic radiation encounters abrupt discontinuities in refractive index, as in a **Fresnel lens** or in the examination of some specimens in (electron) microscopy. [After Augustin Jean Fresnel (1788–1827), French physicist.]

Fresnel lens a lens whose surface consists of a concentric series of lens sections (or one convex surface and one stepped surface). This arrangement allows a thin lens of short focal length and large diameter to be easily made, and finds application in searchlights, viewing devices, and overhead projectors.

fret a broad membrane-bound channel interconnecting the grana of chloroplasts.

FRET *abbr.* for fluorescence resonance energy transfer.

Freund's adjuvant a widely used immunological **adjuvant** (def. 1), used to produce water-in-oil emulsions with aqueous antigens or antigen preparations. It consists of a mixture of mineral oil and emulsifier (**incomplete Freund's adjuvant**) in which killed mycobacteria have been dispersed (**complete Freund's adjuvant**). Omission of mycobacteria may modify the duration, intensity, and nature of the responses. [After Jules Freund (1891–1960).]

Frey-Wyssling particle a double-membrane particle (4–6 μm in diameter) representing a minor component of rubber latex. [After Albert Frey-Wyssling (1900–).]

FRF *abbr.* for follicle-stimulating-hormone-releasing factor; *see* **gonadotropin-releasing hormone**.

FRH *abbr.* for follicle-stimulating hormone releasing hormone; *see* **gonadotropin-releasing hormone**.

friable easily crumbled or pulverized.

friction the resistance to the relative motion of one body sliding, rolling, or flowing over another body with which it is in contact. — **frictional adj.**

frictional coefficient or **frictional constant** *symbol*: f ; the frictional force opposing the motion of a body in a fluid medium divided by the velocity of movement. It may be expressed in different ways. The **translational frictional coefficient**, f_t , for a rigid sphere of radius r moving at low velocity through a medium of viscosity η , is given by: $f_t = 6\pi\eta r$ (**Stokes' law of viscosity**). For particles of other shapes additional terms must be included. The **rotational frictional coefficient**, f_{rot} , is a parameter relating the velocity of rotation of a rigid

sphere of volume V in a fluid medium of viscosity η . It is given by: $f_{\text{rot}} = 6\eta V$. *See also* **frictional ratio**.

frictional force the force exerted on a particle moving through a fluid medium as a result of friction. It is the product of the velocity, relative to the medium, of the particle and its **frictional coefficient**.

frictional ratio the ratio of the experimentally determined translational **frictional coefficient**, f_t , of a hydrated, anisotropic macromolecule to the calculated frictional coefficient, f_{t0} , of a nonhydrated spherical macromolecule of the same molecular mass. The ratio f_t/f_{t0} gives some indication of the asymmetry of the macromolecule.

Friedreich's ataxia an autosomal recessive inherited disease that involves the central and peripheral nervous systems and the heart. It is the most common hereditary ataxia, and is associated with defects in the gene encoding **frataxin**. [After Nikolaus Friedreich (1825–1882), German neurologist.]

Friend cell a cell of a cultured cell line of leukemic mouse erythroblasts obtained by transformation with Friend leukemia virus. In such cells development is arrested before any globin synthesis occurs, but treatment with certain chemicals, e.g. dimethylsulfoxide, causes a resumption of development and hemoglobin synthesis.

Friend leukemia virus a strain of mouse type C oncovirus that specifically affects immature erythroid cells in mice to cause an erythroleukemia. [After Charlotte Friend (1921–).]

friend of GATA-1 *see* **FOG1**.

frit filter or **frittled filter** or **frittled glass filter** an alternative name for **sintered glass filter**.

Frizzled any of a family of G-protein-coupled plasma membrane receptors present throughout the animal kingdom. The N-terminal extracellular segment contains a cysteine-rich domain (called the FRZ domain) of ≈ 120 amino acids, which binds a Wnt protein. The domain also occurs in secreted Wnt antagonists such as WIF-1.

Fromm's method a kinetic approach for studying the mechanism of action of enzyme systems that utilize three substrates. Such systems may be divided into two groups on the basis of their initial rate expressions: the first group is made up of sequential pathways of enzyme and substrate interaction alone, the second is the ping-pong type. The mechanisms in each category may further be separated either by initial rate measurements or from studies with competitive inhibitors. [After Herbert Jerome Fromm (1929–), US biochemist.]

frontal analysis any analytical technique by which the progress of the separation of components of a mixture, as by frontal chromatography, moving boundary electrophoresis, or analytical ultracentrifugation, is followed, and the relative proportions of the components determined, by examination of the individual boundaries, or fronts, formed by each component with the solvent.

frontal chromatography a technique for chromatographic separation in which the sample (liquid or gas) is fed continuously into the chromatographic bed and only the component that emerges first is obtained in pure form.

fronting (*in chromatography*) the asymmetry of a peak such that, relative to the baseline, the front is less steep than the rear. In paper chromatography and thin-layer chromatography it refers to the distortion of a zone showing a diffuse region preceding the zone in the direction of flow.

frontside attack the mechanism of a chemical displacement reaction in which the configuration is retained.

frozen replica method an alternative name for **freeze-etching**.

FRS *abbr.* for Fellow of the Royal Society (of London).

FRSE *abbr.* for Fellow of the Royal Society of Edinburgh.

Fru *symbol* for a residue (or sometimes a molecule) of the ketohexose **fructose**. In the condensed system of symbolism of sugar residues, Fru signifies specifically a fructose residue with the common configuration and ring size, i.e. D-fructofuranose.

fructan any **glycan** composed only of D-fructose residues. Fructans occur commonly as food reserves in the roots, stems, leaves, and seeds of many plants, e.g. in tubers of dahlias and Jerusalem artichokes. There are two main types: (1) inulin-type, in which the fructofuranose residues are linked by $\beta 2 \rightarrow 1$ glycosidic linkages; and (2) levan-type, in which the linkages are $\beta 2 \rightarrow 6$, which were formerly referred to as **fructosans**.

β -fructofuranosidase EC 3.2.1.26; *other names*: invertase; saccharase; an enzyme that catalyses the hydrolysis of terminal nonreduc-

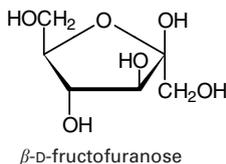

ing β -D-fructofuranoside residues in β -D-fructofuranosides, e.g. sucrose.

fructokinase 1 *the recommended name for the enzyme ATP:D-fructose 6-phosphotransferase*; EC 2.7.1.4; this catalyses the phosphorylation of D-fructose by ATP to form D-fructose 6-phosphate and ADP. The enzyme occurs in plants and in schistosomes, and is highly specific for D-fructose. In bacteria it is important in fructose utilization. Structurally it is similar to other carbohydrate kinases. **2** *an alternative name for ketohexokinase* (EC 2.7.1.3). This usage is misleading since ketohexokinase yields D-fructose 1-phosphate.

fructosaccharase *a trivial name for any saccharase that attacks the fructose-containing end of appropriate oligosaccharides, liberating fructose.*

fructosan 1 (formerly) *a trivial name for 2,6-anhydrofructofuranose. 2* *an (older) incorrect name for fructan.*

fructose *symbol:* Fru; *the trivial name for the ketohexose arabino-2-hexulose*; there are two enantiomers. D-(–)-fructose (*symbol:* D-Fru), commonly known as fructose, and formerly known as **fruit sugar**, is levorotatory, hence formerly known also as **levulose** or (*esp. UK*) **laevulose**; it is the sweetest of the sugars. Aqueous solutions of D-fructose at room temperature contain an equilibrium mixture of β -D-fructopyranose, β -D-fructofuranose, α -D-fructofuranose, and the open-chain form, whereas in crystals the sugar is present entirely as β -D-fructopyranose. Combined D-fructose is almost invariably in the furanose form, however. D-fructose is found free in a large number of fruits, in honey, and (as the sole sugar) in bull and human semen. In combined form it occurs at one residue per molecule of the disaccharide **sucrose** and the trisaccharides **gentianose**, **melezitose**, and **raffinose**, and as the sole component of the polysaccharide **fructans**.

fructose-bisphosphatase EC 3.1.3.11; *systematic name:* D-fructose-1,6-bisphosphate 1-phosphohydrolase; *other names:* hexosediphosphatase; (*formerly:*) fructose-1,6-diphosphatase. A phosphoric monoester hydrolase that hydrolyses D-fructose 1,6-bisphosphate to D-fructose 6-phosphate and orthophosphate. It is important in **gluconeogenesis** and in regulation of the **reductive pentose phosphate cycle** in chloroplasts.

fructose-2,6-bisphosphatase an enzyme that hydrolyses fructose 2,6-bisphosphate to fructose 6-phosphate; it is the same protein as phosphofructokinase-2. *See phosphofructokinase* (def. 2).

fructose-1,6-bisphosphatase deficiency *see hereditary fructose-1,6-bisphosphatase deficiency.*

fructose 1,6-bisphosphate or (*formerly*) **fructose 1,6-diphosphate** *abbr.:* FBP; the D enantiomer is a metabolic intermediate in **glycolysis** and **gluconeogenesis**.

fructose 2,6-bisphosphate the D enantiomer is an important regulator of the **glycolytic** and **gluconeogenic pathways**. It inhibits fructose 1,6-bisphosphatase and activates phosphofructokinase, and its concentration is controlled by the **phosphofructokinase** (def. 2) and fructose 2,6-bisphosphatase activities of a 49 kDa protein.

fructose-bisphosphate aldolase *see aldolase* (def. 2).

fructose-2,6-bisphosphate 2-phosphatase EC 3.1.3.46; *other name:* fructose-2,6-bisphosphatase; an enzyme that catalyses the hydrolysis of D-fructose 2,6-bisphosphate to D-fructose 6-phosphate and orthophosphate, being part of the system for regulating the concentration of fructose 2,6-bisphosphate. This enzyme is the phosphorylated form of the protein. If dephosphorylated, it functions as a 2-kinase for fructose 6-phosphate. *See also phosphofructokinase* (def. 2).

fructose-1,6-diphosphatase *a former name for fructose-bisphosphatase.*

fructose 1,6-diphosphate *a former name for fructose 1,6-bisphosphate.*

fructose disease *see essential fructosuria, hereditary fructose intolerance, hereditary fructose-bisphosphatase deficiency.*

fructose intolerance *an alternative name for essential fructosuria.*

fructose 6-phosphate *abbr.:* F6P; the D enantiomer is an important intermediate in glycolysis, gluconeogenesis, and fructose metabolism.

fructosuria the presence of abnormal amounts of fructose in the urine. *See also essential fructosuria.*

FruF *symbol for a fructofuranose residue.*

fruit the structure that develops from the fertilized ovary of a flowering plant and contains the ripening seed or seeds. It may be fleshy or dry; the term is often extended to include other associated parts such as a fleshy receptacle.

fruit fly a common name for species of flies belonging to the genus *Drosophila*.

fruit-ripening hormone *see ethylene.*

fruit sugar *a former name for the D enantiomer of fructose.*

Fse I a type 2 **restriction endonuclease**; recognition sequence: GGC-CGG↑CC.

FSF *abbr. for fibrin-stabilizing factor* (i.e. factor XIIIa); *see blood coagulation.*

FSH *abbr. for follicle-stimulating hormone.*

FSH-RF *abbr. for follicle-stimulating hormone releasing factor; see gonadotropin-releasing hormone.*

FSH-RH *abbr. for follicle-stimulating hormone releasing hormone; see gonadotropin-releasing hormone.*

F₁ sphere a submitochondrial structure containing the catalytic site for ATP synthesis.

F'-strain a bacterial strain containing an **F' plasmid**.

FtsZ a bacterial GTPase that is crucial for assembly of the **Z ring** in the mid-region of the plasma membrane inner surface. It is the first protein to localize to the future site of cell division. Highly conserved in eubacteria and archaea, it also occurs in most groups of land plants and in many algae, and resembles eukaryotic tubulin. Its correct localization requires the Min system.

F-type pentose phosphate pathway *see pentose phosphate pathway.*

ftz the gene for Fushi Tazaru protein, a nuclear DNA-binding homeobox segmentation protein from *Drosophila melanogaster*.

FU *abbr. for fluorouracil* (use proscribed; the symbol FUra is recommended).

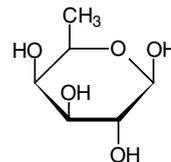

Fuc *symbol for a residue* (or sometimes a molecule) of the deoxyaldohexose **fucose**. In the condensed system of symbolism of sugar residues, Fuc signifies specifically a fucose residue with the common configuration and ring size, i.e. L-fucopyranose.

fucan a **glycan** composed only of fucose residues.

fucoidan or **fucoidin** any of a group of complex branched, sulfated heteropolysaccharides that are composed of residues of L-fucose (usually sulfated) together with small numbers of residues of various other monosaccharides. Fucoidans occur in the cell walls, intercellular matrix, and exuded mucilage of many (especially intertidal) species of marine algae, in which they appear to assist in water retention during periodic exposure.

fucosamine 2-amino-2,6-dideoxygalactose; an aminodeoxysugar, both enantiomers of which occur in lipopolysaccharides of *Salmonella* and other bacterial genera.

fucose *symbol:* Fuc; *the trivial name for 6-deoxygalactose*; there are two enantiomers. D-fucose (*symbol:* D-Fuc), 6-deoxy-D-galactose,

β -D-fucose

occurs in glycosides in various plants belonging to the Convolvaceae. L-fucose (*symbol*: L-Fuc), 6-deoxy-L-galactose, occurs in polysaccharides (fucans) in seaweeds, especially *Fucus* spp., and in the cell wall matrix of higher plants. In animals fucosyl residues occur in a number of glycoproteins and glycolipids; the presence of α -1,4-linked L-fucosyl residues at specific positions in the highly branched oligosaccharides of human erythrocyte surface antigens is controlled by the *H* and *Le* blood-group genes.

fucose-1-phosphate guanlyltransferase EC 2.7.7.30; *other name*: GDPfucosepyrophosphorylase; an enzyme that catalyses the formation of GDP-L-fucose from GTP and L-fucose 1-phosphate with release of pyrophosphate.

α -fucosidase any of several enzymes that hydrolyse α -fucosides. **1** α -fucosidase, EC 3.2.1.151; *systematic name*: α -L-fucoside fucosylhydrolase; it catalyses the hydrolysis of an α -L-fucoside to an alcohol and L-fucose. **2** 1,3- α -L-fucosidase, EC 3.2.1.111; *other names*: almond emulsin; fucosidase I; an enzyme that catalyses the hydrolysis of 1,3-linkages between α -L-fucose and *N*-acetylglucosamine residues in glycoproteins. **3** 1,6- α -L-fucosidase, EC 3.2.1.127; an enzyme that catalyses the hydrolysis of 1,6-linkages between α -L-fucose and *N*-acetyl-D-glucosamine in glycopeptides such as immunoglobulin G glycopeptide and fucosyl-asialo-agalacto-fetuin.

fucosidosis a rare autosomal recessive disorder characterized by progressive psychomotor and growth retardation; urinary excretion and lysosomal accumulation of glycolipids, glycopeptides, and oligosaccharides that contain terminal fucose moieties; and α -fucosidase deficiency. Mutations in the gene at 1p24 are responsible.

FdUR or **FUDR** *abbr. for* fluorodeoxyuridine (use deprecated; the symbol FdUrd is recommended).

fugu a teleost fish, *Takifugu rubripes*, used as a model experimental organism. Sequencing of the fugu genome has enabled valuable comparisons with other organisms. Fugu has a similar number of genes to mammals, but the fugu genome is much smaller at 390 Mbp, one-eighth the size of the human genome.

fugu toxin *see* tetrodotoxin.

fukuatin a protein (461 amino acids, gene at 9q31-q33) implicated in Fukuyama type congenital muscular dystrophy, which is associated with dysplasia of cerebral cortex, epilepsy, and severe mental retardation. Its localization and function are still unclear.

full agonist an **agonist** that is able to elicit the maximal response of a tissue even when the tissue has spare receptors. In such a situation, several different agonists may be able to elicit the same maximal response, albeit at different receptor occupancies. Moreover, a full agonist in one tissue may be a **partial agonist** in another.

fuller's earth a naturally occurring, porous, absorptive aluminium-magnesium silicate clay. It is useful for decolorizing oils and other liquids and as a filtering medium. It is so-called because it was originally used to full (i.e. cleanse and thicken) wool and woollen cloth.

full-shotgun coverage *see* depth of coverage.

fully overlapping code *see* overlapping code.

fumarase EC 4.2.1.2; *recommended name*: fumarate hydratase. An enzyme of the **tricarboxylic-acid cycle** that catalyses the reaction:

There are two different enzymes in facultative bacteria (e.g. *Escherichia coli*). In humans a cytosolic and a mitochondrial isoform are derived from the gene at 1q42.1. A missense mutation produces deficiency of both isoforms and results in neurological impairment and neuropathy, fumaric aciduria, and increased urinary excretion of succinate, 2-oxoglutarate, and citrate. Mutations are also associated with hereditary fibroids of skin and uterus, suggesting that the protein is a tumour suppressor.

fumarate 1 the *trivial name for* *trans*-1,2-ethylenedicarboxylate, (*E*)-butenedioate, the dianion of fumaric acid; the diastereoisomer of **malate** and a key intermediate in metabolism. In the tricarboxylic-acid cycle it is formed from succinate by **succinate dehydrogenase**, and is converted to malate by **fumarase**. **2** any mixture of fumaric acid and its mono- and dianions. **3** any salt or ester of fumaric acid.

fumarate hydratase *see* fumarase.

fumarate reductase an enzyme in the respiratory chains of anaerobic bacteria that catalyses the reduction of fumarate by menaquinol to form succinate and menaquinone. *E. coli* fumarate reductase is an iron-sulfur flavoprotein (FAD), containing at least four different subunits: a flavoprotein, an iron-sulfur protein, and two hydrophobic anchor proteins.

fumaroyl the bivalent *trans*-acyl group, -CO-CH=CH-CO- , derived from fumaric acid.

fumaryl the univalent *trans*-acyl group, HOOC-CH=CH-CO- , derived from fumaric acid.

fumed silica a preparation of pure silicon dioxide as an extremely fine, white powder with an external surface area of up to $400 \text{ m}^2\text{g}^{-1}$. It is useful for thickening and forming thixotropic gels. Fumed silica is used as a suspending and gelling agent in liquid-scintillation counting; a 3–5 concentration in dioxan, toluene, or xylene-based liquid scintillators will form an almost transparent, rigid gel, capable of holding an insoluble solid sample in suspension. *Proprietary name*: Cab-O-Sil.

fume hood a work space contained under a hood from which air is extracted to remove harmful vapours.

function 1 (*in chemistry*) a **functional group**. **2** (*in mathematics*) a either of two variables so related to each other that for any value of one variable there is a corresponding value of the other. **b** a variable or expression that can take a set of values each of which is associated with the magnitude of an independent variable or variables. **3** (*in physiology*) the normal vital activity of a cell, organ, or tissue within an organism. —**functional adj.**

functional antagonism 1 antagonism arising by the antagonist's producing an opposite effect to the substance being antagonized through the antagonist's action at a different receptor. **2** antagonism arising when the antagonist interferes with events that follow receptor activation by the substance being antagonized.

functional cloning a cloning strategy in which knowledge of a gene's product (function) is used to clone the gene. An example is the gene for the β chain of hemoglobin responsible for sickle-cell anemia. This is in contrast to **structural cloning** where the function of the gene is not known. A common procedure would be to construct a DNA oligonucleotide based on the amino-acid sequence of the peptide and use this as a probe to isolate the gene from a DNA library. In cases where one protein is dominant in a cell, such as hemoglobin in the reticulocyte, the preparation of a cDNA from the mRNA also provides a useful probe for gene isolation.

functional genomics the systematic analysis of genes, their encoded proteins, and the relationships between gene activity and cell function at the level of whole genomes.

functional group or **function** (*in chemistry*) any **group** (def. 1) in a molecule of an organic compound that confers characteristic chemical and physical properties on the molecule and that may be considered to have replaced a hydrogen atom in a molecule of the corresponding hydrocarbon, e.g. the hydroxyl group in an alcohol.

functional polymer 1 a polymer that bears specified chemical groups. **2** a polymer that has specified physical, chemical, biological, pharmacological, or other uses. Examples of functions include: catalytic activity; selective binding of particular species; capture and transport of electric charge carriers or energy; and transport of drugs to a particular organ in which the drug is released.

fungicide any biological, chemical, or physical agent able to destroy fungi. —**fungicidal adj.**

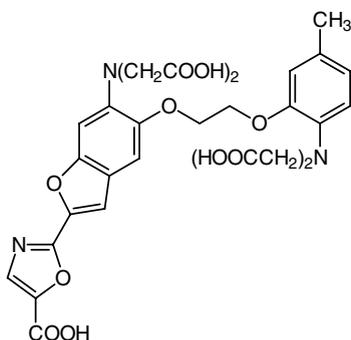

fungistat any drug, antibiotic, or other agent that inhibits the growth and multiplication of fungi. —**fungistatic adj.**

fungus (*pl. fungi*) any member of the taxonomic kingdom Fungi, a group of diverse and widespread unicellular, multicellular, or eukaryotic organisms that do not contain chlorophyll. Fungi may be parasitic, saprophytic, or symbiotic. They reproduce through spores. *See also* microfungus. —**fungal adj.**

FUR *abbr.* for fluorouridine (use proscribed; the symbol FUrD is recommended).

FUra *symbol* for (a residue of) the synthetic pyrimidine base **fluorouracil**.

Fura 2 1-[2-(5-carboxyoxazol-2-yl)-6-aminobenzofuran-5-oxyl]-2-(2'-amino-5'-methylphenoxy)-ethane-*N,N,N',N'*-tetraacetic acid; a highly sensitive calcium ion chelator that exhibits a spectral shift on binding Ca^{2+} . Calcium ion concentration can be measured directly, independent of dye concentration, by measuring the ratio of fluorescence at 510 nm after excitation at 340 nm and then at 380 nm. It is frequently used as the acetoxymethyl ester (Fura 2/AM, Fura 2-pentakis(acetoxymethyl)ester), which is a membrane-permeable derivative that can enter cells, after which it is rapidly hydrolysed by cytoplasmic esterases to Fura 2, which remains trapped within the cell and can thus report the intracellular Ca^{2+} concentration. See also **Quin-2**.

furan the trivial name for oxa-2,4-cyclopentadiene, $\text{C}_4\text{H}_4\text{O}$. See also **furanose**.

furanoid furan-like, i.e. describing a molecular structure that consists of or contains a ring of four carbon atoms and one oxygen atom (as in furan).

furanose *symbol:* *f*; any monosaccharide or monosaccharide derivative whose molecule contains a furanoid ring. Compare **pyranose**, **septanose**.

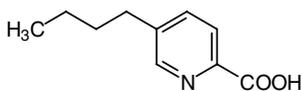

furanoside any glycoside in which the sugar moiety is in the furanose form.

FUrD *symbol* for (a residue of) the ribonucleoside fluorouridine (see **fluorouracil**).

furin the mammalian counterpart of **kexin**.

furyl either 2-furyl or 3-furyl, the two oxa-2,4-cyclopentadienyl groups derived from a molecule of **furan** by loss of a hydrogen atom from C-2 and C-3 respectively.

fusaric acid 5-butylpyridine-2-carboxylic acid; an antibiotic originally isolated from the fungus *Fusarium heterosporium* and obtained also from *Gibberella fujikuroi*. It inhibits **dopamine β -hydroxylase** and has hypotensive activity.

fused ring (*in chemistry*) any ring of atoms in a molecule that is joined to another ring of atoms in such a way that two atoms are common to both rings.

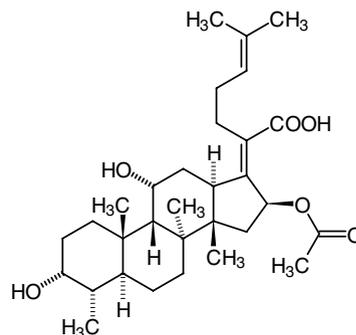

fused rocket immunoelectrophoresis a modification of **rocket immunoelectrophoresis** designed to follow the distribution of proteins among the fractions obtained in a separation experiment. Small volumes of fractions obtained in the separation experiment are placed in a row of sample wells in an antibody-free agarose gel and the samples are allowed to diffuse into the gel for 30–60 min. The proteins are then forced at right angles into an antibody-containing gel by electrophoresis; the resulting precipitation lines (rockets) show the elution profiles for each individual protein in the separa-

tion experiment and the distance between the precipitation line and the corresponding well is proportional to the amount of antigen precipitated.

fusel oil a colourless, oily liquid of variable composition obtained as a by-product in the distillation of alcoholic fermentation liquors. It contains chiefly isopentanol, 2-methyl-1-butanol, isobutanol, and propanol. It is considerably more toxic than ethanol. [From German *fuseln*, to bungle.]

fusiococcin a toxin produced by the fungus *Fusicoccus amygdali* that infects peach and almond trees. Its receptor is a 14.3.3 protein that binds proteins containing a conserved sequence that includes a phosphorylated serine residue. It activates the plasma membrane H^+ ATPase in a variety of plant cell types, induces stomatal opening and consequent wilting of leaves, enhances growth rates, and breaks seed dormancy.

fusidic acid $3\alpha,11\alpha,16\beta$ -trihydroxy-4 $\alpha,8,14$ -trimethyl-18-nor-5 $\alpha,8\alpha,9\beta,13\alpha,14\beta$ -cholesta-17(20),24-dien-21-oic acid 16-acetate; a steroid antibiotic, structurally related to cephalosporin P (see **cephalosporin**) and isolated from the fermentation broth of *Fusidium coccineum*. Fusidic acid is active particularly against Gram-positive organisms, especially *Staphylococcus* spp. It prevents translocation during protein synthesis and inhibits the accumulation of ppGpp.

fusiform spindle-shaped; elongated and tapering at both ends.

fusin or **HIV entry cofactor**; a putative G-protein-coupled membrane receptor (352 amino acids) that cooperates with CD4 on immune cell surfaces and permits them to fuse with the HIV surface. It shows 37% sequence identity with the interleukin 8 (IL-8) receptor.

fusion 1 the act or process of melting. **2** the act or process of melting together or uniting. **3** the process whereby two membranes are joined together, as in **cell fusion**. **4** the process whereby nuclei of light elements are united to form nuclei of heavier elements with the release of energy: **nuclear fusion**. **5** the state of being fused. **6** something produced by fusion. **7** (*in molecular biology*) the act, process, or result of artificially linking genes that code for two different proteins, with the aim of generating a **fusion protein**.

fusion protein an expression product resulting from the fusion of two genes. Such a protein may be produced, e.g., in recombinant DNA expression studies or, naturally, in certain viral **oncogenes** in which the oncogene is fused to **gag**. Their production sometimes results from the need to place a cloned eukaryotic gene under the control of a bacterial promoter for expression in a bacterial system; sequences of the bacterial system are then frequently expressed linked to the eukaryotic protein. Fusion proteins are used for the analysis of structure, purification, function, and expression of heterologous gene products.

fusogen any agent, or set of conditions, that gives rise to fusion of membranes, including cell membranes (and hence of cells). Killed Sendai virus was formerly much used for this purpose but now polyethylene glycol is commonly used as a fusogen particularly in the preparation of hybridomas for the production of monoclonal antibodies. —**fusogenic** *adj.*

futile cycle any metabolic cycle that, if not controlled, acts as an ATPase and hence converts chemical energy (stored as ATP) to heat. For example, a coupling of phosphofructokinase, which converts fructose 6-phosphate to fructose 1,6-bisphosphate at the ex-

pense of ATP, with fructose-bisphosphatase, which hydrolyses fructose 1,6-bisphosphate to fructose 6-phosphate and (inorganic) phosphate, can form a cyclic process whose net effect is merely the hydrolysis of ATP to ADP and phosphate. A futile cycle may be an important control mechanism in some physiological conditions.

fuzzy coat or **fuzzy layer** the indistinct layer seen on electron microscopy outside the cell coat of various eukaryotic cells, e.g. cells of mammalian intestinal epithelium and a number of single-celled amoebae. It is composed principally of glycoproteins.

fuzzy onions *abbr.*: *fzo*; a mutant of *Saccharomyces cerevisiae* in which mitochondria undergo abnormal fission with fragmentation.

Fv fragment the N-terminal part of the **Fab fragment** of an immunoglobulin molecule, consisting of the variable portions of one light chain and one heavy chain.

FXR *abbr.* for farnesoid X receptor.

FYN a gene family encoding nonreceptor tyrosine kinases of the Src family (see **src**) that are implicated in the control of cell growth. The

gene product, p59^{*fyn*}, associates with the p85 subunit of **1-phosphatidylinositol 3-kinase**. The proteins undergo myristoylation and phosphorylation on serine and tyrosine residues; overexpression transforms fibroblasts. The alternative gene symbols are *SYN* (from *src/yes*-related novel gene) and *SLK*.

FYVE a protein sequence of ≈ 70 amino acids that contains two zinc atoms coordinated by eight cysteine residues, the third cysteine being surrounded by a highly conserved basic sequence. It forms two pairs of antiparallel beta strands stabilized by coordination with the zinc atoms, termed the **FYVE finger**. The name is based on the first letters of four proteins containing this motif, although this is not found in all proteins of this type. The basic residues form a shallow groove that can accommodate the phosphate group of phosphatidylinositol 3-phosphate. It occurs in many proteins of numerous species (from yeast to mammals) and is involved in membrane trafficking. See **FGD1**.

Gg

g symbol for 1 gram. 2 gaseous state. 3 gluon.

g 1 symbol for acceleration of free fall (formerly known as acceleration due to gravity). 2 *abbr. for gauche*. 3 symbol for the electron g-value.

g_n symbol for standard acceleration of free fall, a fundamental physical constant equal by definition to 9.806 65 m s⁻².

g_N nuclear g-value; a constant for any nucleus that defines the energy of interaction with a magnetic field, e.g. in **NMR spectroscopy**.

G symbol for 1 giga+ (SI prefix denoting 10⁹ times). 2 gauss (alternative to Gs). 3 a residue of the α-amino acid glycine (alternative to Gly). 4 a residue of the base guanine in a nucleic-acid sequence. 5 a residue of the ribonucleoside guanosine (alternative to Guo). 6 a residue of the monosaccharide glucose (alternative to Glc). 7 ganglioside.

G symbol for 1 Gibbs energy. 2 gravitational constant. 3 weight (alternative to *W* or *P*). 4 electric conductance.

G418 a proprietary name for the aminoglycoside antibiotic geneticin. Resistance to the antibiotic is conferred by the bacterial gene *neo^R*, which encodes aminoglycoside-3'-phosphotransferase.

Ga symbol for gallium.

Ga₂ symbol for galabiose (alternative to GaOse₂).

Ga₃ symbol for galatriaose (alternative to GaOse₃).

G_M *abbr. for monosialoganglioside*.

GA *abbr. (sometimes) for 1 glyceric acid. 2 glutamic acid. 3 glucuronic acid.*

GAA a codon in mRNA for L-glutamic acid.

GABA *abbr. for γ-amino-n-butyric acid or γ-aminobutyrate.*

GABAergic 1 describing a nerve or other cell that is acted upon by γ-aminobutyrate. 2 describing nerves that act by releasing γ-aminobutyrate.

GABA-gated channel *see GABA receptor*.

GABA-modulin a brain protein that down-regulates the high-affinity binding site for γ-amino-n-butyric acid (GABA) on synaptic membranes.

GABA receptor any of several membrane proteins that bind γ-aminobutyrate (GABA) and mediate its effects as an inhibitory neurotransmitter. GABA_A receptors, known also as GABA-gated channels, function as a Cl⁻ channel; GABA_B receptors are G-protein-coupled receptors. **Baclofen** is a potent GABA mimetic that is selective for the GABA_B receptor; **muscimol** is its counterpart for the GABA_A receptor. The GABA_A receptor is multimeric, with α (types α1–α6), β (types β1–β4), γ (types γ1–γ3), δ, and ρ subunits. Subunits α and β have four putative transmembrane segments that show some homology with those seen in the nicotinic acetylcholine receptor (nAChR) (*see cholinergic receptor*). Increased Cl⁻ ion flux brings about hyperpolarization of an excitatory neuron, which inhibits it from firing on receipt of a normal impulse. **Benzodiazepine** drugs interact with GABA_A receptors at the γ subunit. GABA_B receptors are coupled through G-proteins to stimulation of outward K⁺ current, inhibition of inward Ca²⁺ channels, inhibition of adenylate cyclase, and stimulation of the phosphatidylinositol–Ca²⁺ system. *See also chloride channel*.

gabase an informal name for aminobutyrate aminotransferase (EC 2.6.1.19).

GABA shunt *abbr. for γ-aminobutyrate shunt*.

GABA transaminase *see 4-aminobutyrate transaminase*.

GAC a codon in mRNA for L-aspartic acid.

G-actin the monomeric form of **actin**.

G_{M2}-activator protein a glycosylated protein (162 amino acids), encoded as a precursor by a gene at 5q32–q33, that is essential for hydrolysis by lysosomal β-hexosaminidase A (*see hexosaminidase*). Deficiency can result from any of four mutations, and is the cause of the AB variant of **Tay–Sachs disease**.

GADD *abbr. for growth arrest and DNA damage*; either of two proteins (GADD45 and GADD153) that are produced in response to oxidative stress, induce temporary arrest of the cell cycle, and may

be involved in DNA repair. Expression of the GADD45 gene is modulated by p53.

Gaddum equation a relationship, suggested to replace the **Hill–Langmuir equation**, that describes the situation when two ligands, A and B, are in equilibrium with a common binding site. It is:

$$P_{AR} = [A]/K_A(1 + [B]/K_B) + [A],$$

where P_{AR} is the proportion of the binding sites occupied by ligand A; the square brackets indicate concentrations. *Compare Schild equation*. [After (Sir) John Henry Gaddum (1900–67), British pharmacologist.]

gadelaidate *the trivial name for (E)-eicos-9-enoate*, CH₃–[CH₂]₉–CH=CH–[CH₂]₇–COO⁻ (*trans* isomer), the anion derived from gadelaidic acid, (*E*)-eicos-9-enoic acid. *Compare gadoleate*.

gadoleate *the trivial name for (Z)-eicos-9-enoate*, CH₃–[CH₂]₉–CH=CH–[CH₂]₇–COO⁻ (*cis* isomer), the anion derived from gadoleic acid, (*Z*)-eicos-9-enoic acid. *Compare gadelaidate*.

gag a gene that encodes the glucosaminoglycan core protein for a **retrovirus**. It is named from group-specific antigen gene, or glucosaminoglycan gene. *See also erbA, erbB*.

GAG 1 a codon in mRNA for L-glutamic acid. 2 *abbr. for glucosaminoglycan*.

GAGA factor a DNA-sequence-specific transcription factor in *Drosophila* that binds to several (GA)_n repeats in the promoter for the Hsp70 gene. It acts in concert with **NURF** to disrupt nucleosome spacing in the promoter region.

Gaia a theory of the role of biota in the maintenance of a climatic homeostasis, proposed by British biochemist James Lovelock (1919–) in 1979. The basic concept is that all of the living organisms that inhabit the earth can be regarded as a single vast organism capable of manipulating the atmosphere, geosphere, and hydrosphere to suit its needs. Lovelock named this organism Gaia, after the Greek goddess of the earth.

Gal symbol for a residue (or sometimes a molecule) of the aldohexose galactose. In the condensed system of symbolism of sugar residues, it signifies specifically a galactose residue with the common configuration and ring size, i.e. D-galactopyranose.

GAL4 a gene involved in the regulation of galactose utilization in yeast. The GAL4 protein has a zinc-finger motif for binding to its upstream activator sequence (UAS), which it then activates, and a site for binding the complex of the GAL80 protein – encoded by the *GAL80* gene – and galactose. When this is bound, activation by GAL4 protein is prevented.

GalA symbol for a residue (or sometimes a molecule) of the uronic acid galacturonic acid.

galabiose symbol: Ga₂ or GaOse₂; *the trivial name for the disaccharide Gal(α1-4)Gal*.

galactan any glycan composed solely of galactose residues. The galactans thus form a subgroup of plant hemicelluloses.

galactitol or *meso-galactitol* or (*formerly*) **dulcitol** *the trivial name for the hexitol formally derived by reduction of the aldehyde group of either D- or L-galactose*. It occurs widely especially in seaweeds and higher plants. It is excreted in human galactokinase deficiency and causes cataracts.

galacto- prefix (*in chemical nomenclature*) indicating a particular configuration of a set of (usually) four contiguous CHOH groups, as in the acyclic form of D- or L-galactose. *See monosaccharide*.

galactoceramide *see galactosylceramide*.

galactocerebroside *see galactosylceramide*.

galactokinase *abbr.:* GLK; EC 2.7.1.6; *systematic name:* ATP:D-galactose 1-phosphotransferase. An enzyme that catalyses the phosphorylation by ATP of D-galactose to D-galactose 1-phosphate, with release of ADP; this initiates the metabolism of galactose. There are two human galactokinases. GLK1, a monomer of 392 amino acids encoded at 17q24, is the major enzyme in various

tissues. Mutations in its gene lead to galactokinase deficiency with galactosemia, urinary excretion of galactose and galactitol, and cataracts. GLK2 is encoded on chromosome 15 and shows 35% sequence homology with GLK1. Its metabolic role is unclear.

galactolipid any **glycolipid** containing one or more residues of galactose and/or *N*-acetylgalactosamine. The term includes **galactosylceramide** and **galactosyldiacylglycerol**.

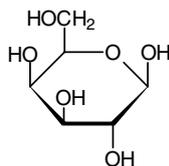

galactomannan any heteroglycan containing D-galactose and D-mannose residues; the structures have not been fully elucidated. They occur in seeds of various plants and trees, probably as storage polysaccharide. *See also* **guaran**.

galactoprotein A *abbr.*: Gap A; *an alternative name for fibronectin*.

galactosaemia a variant spelling (*esp. Brit.*) of **galactosemia**.

galactosamine *symbol*: GalpN; *the trivial name for the amino-deoxysugar 2-amino-2-deoxygalactopyranose*; there are two enantiomers, D- and L-galactosamine. D-Galactosamine (*symbol*: D-GalpN), formerly known as **chondrosamine**, is a constituent (commonly as its *N*-acetyl derivative) of some glycolipids and of chondroitin sulfate, dermatan sulfate, and many bacterial glycosaminoglycans.

galactose *symbol*: Gal; *the trivial name for the aldohexose galactohexose*; there are two enantiomers, D- and L-galactose. D-Galactose (*symbol*: D-Gal), commonly known as galactose, and formerly known as **brain sugar** or **cerebrose**, rarely occurs free but is widely distributed in combined form in plants, animals, and microorganisms as a constituent of many oligo- and polysaccharides; it occurs also in **galactolipids** and as its glucoside in **lactose** and **melibiose**. Residues of both D-galactose and 3,6-anhydro-L-galactose (*symbol*: 3,6An-L-Gal) occur in the disaccharide **agarobiose** and in polysaccharides such as **agaropectin** and **agarose**.

β -D-galactose

galactose/glucose binding protein a signal transducing protein for bacterial chemotaxis.

galactosemia or (*esp. Brit.*) **galactosaemia** comparatively rare condition in humans in which there is a supranormal concentration of D-galactose in the blood and a specific inability to metabolize galactose. It is caused either by (1) a hereditary autosomal recessive trait in which there is a virtual absence of **UDPglucose-hexose-1-phosphate uridylyltransferase** activity; or less frequently (2) an inherited autosomal recessive trait in which there is a deficiency in **galactokinase** activity.

galactose oxidase EC 1.1.3.9; a copper-containing enzyme that catalyses the oxidation by dioxygen of D-galactose to D-galactohexodialdase and H₂O₂.

galactose-1-phosphate uridylyltransferase *see* **UDPglucose-hexose-1-phosphate uridylyltransferase**.

galactose-6-sulfate sulfatase *see* ***N*-acetylgalactosamine-6-sulfatase**.

galactosialidosis a lysosomal storage disorder, transmitted as an autosomal recessive trait, that results from deficiency of three lysosomal enzymes: protective protein/cathepsin A (PPCA), β -galactosidase, and neuraminidase. This causes accumulations of sialooligosaccharides in lysosomes and their excretion in urine. Three clinical phenotypes are recognized on the basis of age of onset and clinical severity: early infantile; late infantile; and juvenile or adult. At least 12 point mutations in the gene at 20q13.1 for PPCA are responsible for the condition.

galactosidase either of two types of enzyme: α -galactosidase EC 3.2.1.22; *systematic name*: α -D-galactoside galactohydrolase; *other name*: melibiase. An enzyme that hydrolytically removes terminal nonreducing α -D-galactose residues in α -galactosides, including

galactose oligosaccharides, galactomannans, and galactolipids. β -galactosidase EC 3.2.1.23; *systematic name*: β -D-galactoside galactohydrolase; *other name*: lactase. An enzyme that removes terminal β -D-galactose residues in β -galactosides by hydrolysis.

galactoside any **glycoside** in which the sugar moiety is galactose.

galactoside acetyltransferase EC 2.3.1.18; *recommended name*: galactoside *O*-acetyltransferase; *systematic name*: acetyl-CoA: β -D-galactoside 6-acetyltransferase; *other name*: thiogalactoside transacetylase. An enzyme that catalyses the acetylation by acetyl-CoA of β -D-galactoside to 6-acetyl- β -D-galactoside with release of GDP. Such an enzyme is the *lacA* gene product in *Escherichia coli* (*see lac operon*). Its function remains unclear.

galactoside 3(4)-L-fucosyltransferase EC 2.4.1.65; *systematic name*: GDP-L-fucose: β -D-galactosyl-*N*-acetyl-D-glucosaminyl-R 4-L-fucosyltransferase; *other name*: Lewis transferase. An enzyme that catalyses the transfer by GDP-L-fucose of fucose to 1,3- β -D-galactosyl-*N*-acetyl-D-glucosaminyl-R to form 1,3- β -D-galactosyl-(α -1,4-L-fucosyl)-*N*-acetyl-D-glucosaminyl-R with release of GDP; this forms the blood group determinant Le^a of **Lewis antigen**. The enzyme also acts on the corresponding 1,4-galactosyl derivative, forming 1,3-L-fucosyl links. It is a type II membrane glycoprotein, and a product of the Lewis blood group locus.

β -galactoside permease any of several transport proteins in bacteria that facilitate the uptake of β -galactosides. An example is melibiose carrier protein from *Klebsiella pneumoniae*. This is responsible for melibiose transport; it is capable of using hydrogen and lithium cations as coupling cations for cotransport, depending on the particular sugar transported (e.g. H⁺-melibiose, Li⁺-lactose), but cannot recognize Na⁺ ions although it is an integral membrane protein of the sodium:galactoside symporter family. *See also* **lactose permease**.

galactosylceramidase EC 3.2.1.46; an enzyme that catalyses the hydrolysis of D-galactosyl-*N*-acylsphingosine to D-galactose and *N*-acylsphingosine.

galactosylceramide *the recommended term for any D-galactosyl-*N*-acylsphingosine, i.e. any cerebroside in which the sugar moiety is D-galactose (less correctly termed galactoceramide or galactocerebroside)*.

galactosylceramide lipidosis or **Krabbe's disease** or **globoid cell leukodystrophy** one of a number of **sphingolipidoses** or sphingolipid lysosomal storage diseases. A rapidly progressive, invariably fatal, hereditary (autosomal recessive) disease of human infants caused by deficient activity of galactocerebroside β -galactosidase (galactosylceramidase; EC 3.2.1.46). Clinical symptoms usually start between the ages of 3 and 6 months and the condition is characterized by severe mental and motor deterioration and the presence of numerous globoid cells containing galactosylceramide in the white matter of the brain.

galactosylceramide sulfotransferase EC 2.8.2.11; an enzyme involved in **sulfatide** biosynthesis that catalyses the reaction between a galactosylceramide and 3'-phosphoadenylylsulfate to form galactosylceramide sulfate and adenosine 3',5'-bisphosphate.

galactosyldiacylglycerol any of a class of lipids in which one or two galactose residues are in glycosidic linkage with a 1,2-diacylglycerol (loosely termed mono- and digalactosyldiacylglycerols), more specifically as, e.g., 1,2-diacyl-*sn*-glycerol 3- β -D-galactoside or (preferred, as glycosphingolipids are named this way) 1,2-diacyl-3- β -D-galactosyl-*sn*-glycerol. They are widely distributed in plants and are the main constituent lipids of chloroplasts, where they occur in the thylakoid membrane. They are also present in mitochondria.

β -1,3-galactosyl-O-glycosyl-glycoprotein β -1,6-*N*-acetylglucosaminyltransferase EC 2.4.1.102; *other names*: *O*-glycosyl-oligosaccharide-glycoprotein; *N*-acetylglucosaminyltransferase I; β^6 -*N*-acetylglucosaminyltransferase; core debranching enzyme; an enzyme that catalyses the reaction between UDP-*N*-acetyl-D-glucosamine and β -D-galactosyl-1,3-*N*-acetyl-D-galactosaminyl-R to form β -D-galactosyl-1,3-(*N*-acetyl- β -D-glucosaminyl-1,6)-*N*-acetyl-D-galactosaminyl-R with release of UDP. It introduces branches into O-linked glycoprotein oligosaccharides.

galactosyltransferase any enzyme belonging to the sub-class hexosyltransferases, EC 2.4.1, for which the glycosyl group is galac-

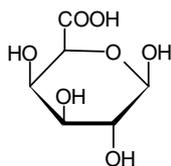

tosyl; the acceptor is typically another carbohydrate molecule or lipid. *See also* **B-transferase**, **lactose synthase**, **Lewis transferase**.

galactowaldenase a former name for **UDPglucose 4-epimerase**.

galacturonan or (formerly) **polygalacturonide** any glycan composed solely of galacturonic-acid residues; a specific kind of glycuronan.

galacturonate 1 the anion of galacturonic acid. **2** any salt or ester of galacturonic acid.

galacturonic acid *symbol*: GalA or (formerly) GalU or GalUA; the uronic acid formally derived from galactose by oxidation of the hydroxymethylene group at C-6 to a carboxyl group. There are two enantiomers, D- and L-galacturonic acid; D-galacturonic acid is a component of plant gums and bacterial cell walls.

β-D-galacturonic acid

galanin a biologically active neuropeptide, with wide distribution in the central neurons of several mammalian species. Human galanin has the 30-residue sequence

GWTLNSAGYLLGPHAVGNHRFSFKNGLTLS.

The peptide effects contraction of smooth muscle of the gastrointestinal and genitourinary tracts, and regulates somatotropin release; it may be involved in the control of adrenal secretion, and is also produced in the islets of Langerhans from stimulated intra-islet nerve terminals. Galanin inhibits insulin release *in vivo* and *in vitro*, and inhibits formation of cyclic AMP in cells stimulated by **glucagon-related peptide**. A fragment, GWTLNSAGYLLGPHAI, is an agonist at the hippocampal galanin receptor.

galaptin any of various proteinaceous, *β*-galactoside-specific, animal lectins of relatively low molecular mass, that are isolated from a number of developing and adult tissues, and are believed to mediate intercellular adhesion in some developmental systems.

galectin a secreted carbohydrate-binding protein that binds CD45 and inhibits its receptor tyrosine phosphatase activity.

gall 1 an abnormal swelling or growth produced by a plant in response to the activities of various fungi, mites, and insects, especially members of the Cynipidae and Cecidomyidae. Insect eggs and larvae are often found in galls. **2** a former name for **bile**.

gallate 1 the anion of gallic acid, 3,4,5-trihydroxybenzoic acid, a phenolic acid. **2** any salt or ester of gallic acid. The esters and polyesters are very widely distributed in angiosperms, usually as **gal-lotannins**.

gall bladder a hollow, muscular organ, found in many vertebrates, that receives dilute **bile** from the liver, concentrates and stores it, and discharges it into the duodenum. *See* **gall stone**.

gallotannic acid *see* **tannic acid**.

gallotannin or **hydrolysable tannin** any **tannin** consisting of a molecule of a polyhydric alcohol (usually glucose) esterified with several gallic-acid molecules, each of which may itself be esterified with a further gallic acid molecule, and so on.

gallstone or **cholelith**; a concretion that forms in the gall bladder. The most common type are light-coloured stones, usually multiple and multifaceted, consisting mostly of cholesterol with some protein and calcium bilirubinate. These usually form as a result of bile stasis, supersaturation with cholesterol, and/or presence of nucleation factors such as glycoprotein in mucus, bacteria, or epithelial cells. They occur in about 20% of women and about 5% of men between 50 and 65 years of age, are usually asymptomatic but may produce epigastric pain and obstructive jaundice. They are usually associated with obesity. Less common are brown or black gritty pigment stones consisting mostly of calcium bilirubinate. These are

likely to be associated with chronic hemolytic anemia, and form at an earlier age.

Galp *symbol* for a galactopyranose residue.

GalpA *symbol* for a residue (or sometimes a molecule) of galactopyranuronic acid.

GalpN *symbol* for a residue (or sometimes a molecule) of the amino-deoxysugar **galactosamine**.

GalpNAc *symbol* for a residue (or sometimes a molecule) of the acetamidodeoxysugar *N*-acetylgalactosamine.

GalU or **GalUA** former *symbol* for **galacturonic acid** (GalA now recommended).

galvanic cell an alternative name for **cell** (def. 3).

gamete a mature reproductive cell whose nucleus (and often cytoplasm) fuses with that of another gamete of similar origin but of opposite sex to form a **zygote**, which develops into a new individual. Gametes are haploid and are differentiated into male (+) and female (−).

gamma *symbol*: γ (lower case) or Γ (upper case); the third letter of the Greek alphabet. For uses *see* **Appendix A**.

gamma chain or **γ chain 1** the **heavy chain** of an IgG immunoglobulin molecule. **2** one of the two types of subunit in a human fetal hemoglobin (Hb F) molecule.

gamma globulin or **γ -globulin** any of a band of serum proteins that migrate most slowly on electrophoresis. In humans, this normally constitutes quantitatively the largest fraction of the total globulins. As the γ -globulins are predominantly antibodies, and are not synthesized in the liver as are virtually all the other serum proteins, the albumin/globulin ratio has traditionally been a useful indicator of liver function. The γ -globulins may be separated from the other serum globulins in pooled adult serum, and may then be used for administration by intramuscular injection to provide passive immunity in premature infants or for those in contact with cases of infectious hepatitis. Such γ -globulin preparations tend to form aggregates spontaneously; these can lead to severe anaphylactic reactions when administered intravenously, owing to their ability to aggregate platelets, and to activate complement and generate C3a and C5a anaphylatoxins. In certain diseases, such as Bruton's congenital agammaglobulinemia, the production of immunoglobulin in affected males is grossly depressed. In patients with myeloma, the γ -globulin band on electrophoresis of serum proteins is markedly more prominent, indicating the presence of a raised antibody against an unknown antigen. *See also* **globulin**.

galaptin any of various proteinaceous, *β*-galactoside-specific, animal lectins of relatively low molecular mass, that are isolated from a number of developing and adult tissues, and are believed to mediate intercellular adhesion in some developmental systems.

gamma helix or **γ -helix** a polypeptide chain conformation in which each amide group forms hydrogen bonds with the group's five residues away in each direction along the chain. It has 5.1 amino-acid residues per turn; the translation along the helical axis is 0.99 Å per residue, 5.03 Å per turn.

gamma-hydroxybutyrate *see* **γ -hydroxybutyrate**.

gamma-peptidase *see* **X-Pro dipeptidase**.

gamma radiation or **γ -radiation** electromagnetic radiation with wavelengths in the range 0.1–100 pm (frequencies 3–3000 EHz) emitted by some atomic nuclei during **transformation** (def. 3). Gamma rays have shorter wavelengths than X-rays and higher photon energies.

gammopathy any pathological increase in production of an immunoglobulin (usually IgM, IgA, or IgG) or Bence-Jones protein. Gammopathies may be monoclonal or polyclonal and are associated with increased immunoglobulin synthesis.

gamone any of a group of biological agents secreted by gametes that act on gametes of the opposite sex to initiate the processes leading to fertilization. They may be **gynagamones**, liberated from female gametes, or **androgamones**, liberated from male gametes.

ganciclovir or **gancyclovir** 9-[(1,3-dihydroxy-2-propoxy)methyl]guanine; a nucleoside analogue of **acyclovir** that is more potent against cytomegalovirus. When phosphorylated by virally encoded thymidine kinase it inhibits DNA synthesis through inhibition of DNA polymerase.

ganglion (*pl.* ganglia) a cluster of nerve cells and associated glial cells located outside the central nervous system.

ganglioside any ceramide oligosaccharide carrying, in addition to other sugar residues, one or more sialic residues. Gangliosides were first isolated from ganglion cells (neurons) of the grey matter of the brain but are in fact widely distributed in vertebrate tissues. They are *N*-acetyl- (or *N*-glycoloyl-) neuraminosyl-(X)osylceramides, where (X) stands for the root name of the neutral oligosaccharide to which the sialosyl residue is attached; the acyl groups in the ceramide moiety are commonly stearoyl or lignoceroyl. Gangliosides are designated by G for ganglioside, plus subscript M, D, or T for mono-, di-, or trisialo, respectively, followed by a subscript arabic numeral to indicate the sequence of migration in thin-layer chromatograms. The principal gangliosides of human brain are:

- (1) monosialogangliosides: G_{M1} , Gal(β 1-3)GalNAc(β 1-4)(NeuAc(α 2-3))Gal(β 1-4)Glc β 1Cer (G_{A1} denotes the asialo derivative of G_{M1}); G_{M2} , GalNAc(β 1-4)(NeuAc(α 2-3))Gal(β 1-4)Glc β 1Cer (G_{A2} denotes the asialo derivative of G_{M2}); G_{M3} , NeuAc(α 2-3)Gal(β 1-4)Glc β 1Cer;
- (2) disialogangliosides: G_{D1a} , NeuAc(α 2-3)Gal(β 1-3)GalNAc(β 1-4)(NeuAc(α 2-3))Gal(β 1-4)Glc β 1Cer; G_{D1b} , Gal(β 1-3)GalNAc(β 1-4)(NeuAc(α 2-8)NeuAc(α 2-3))Gal(β 1-4)Glc β 1Cer; G_{D3} , NeuAc(α 2-8)NeuAc(α 2-3)Gal(β 1-4)Glc β 1Cer;
- (3) trisialogangliosides: G_{T1a} , NeuAc(α 2-8)NeuAc(α 2-3)Gal(β 1-3)GalNAc(β 1-4)(NeuAc(α 2-3))Gal(β 1-4)Glc β 1Cer; G_{T1b} , NeuAc(α 2-3)Gal(β 1-3)GalNAc(β 1-4)(NeuAc(α 2-8)NeuAc(α 2-3))Gal(β 1-4)Glc β 1Cer.

ganglioside galactosyltransferase EC 2.4.1.62; *other name*: UDPgalactose–ceramide galactosyltransferase; an enzyme that catalyses the reaction between UDPgalactose and *N*-acetyl-D-galactosaminyl-(*N*-acetylneuraminyl)-D-galactosyl-D-glucosyl-*N*-acylsphingosine to form the **ganglioside** G_{M1} , with release of UDP.

gangliosidosis any of a group of inherited human diseases involving defects in **ganglioside** breakdown. They are characterized by: progressive mental and motor deterioration with fatal outcome; autosomal recessive inheritance; neuronal lipidosis secondary to storage of gangliosides and structurally related glycolipids, polysaccharides, or glycoproteins; and absence or severe deficiency of specific lysosomal glycohydrolases. The principal gangliosidoses are G_{M1} and G_{M2} gangliosidoses (the names indicating which ganglioside accumulates). G_{M1} gangliosidoses are due to a striking deficiency of β -galactosidase activity when tested using G_{M1} or galactose-containing glycoproteins as substrates. Type 1 or infantile G_{M1} gangliosidosis is a generalized gangliosidosis with bony involvement and onset of signs from birth or shortly after. Type 2 or juvenile G_{M1} gangliosidosis is of slower onset than type 1 and with milder bony abnormalities. There are three types of G_{M2} gangliosidosis. Type 1 G_{M2} gangliosidosis (*or* **Tay–Sachs disease**) is the commonest gangliosidosis, occurring especially in Ashkenazi Jews. It is caused by a severe deficiency of hexosaminidase A. Type 2 G_{M2} gangliosidosis (*or* **Sandhoff's disease**) occurs much less frequently than Tay–Sachs disease and is caused by severe deficiency of both hexosaminidases A and B; globoside accumulates in addition to G_{M2} in this disease. Type 3 or juvenile G_{M2} gangliosidosis is caused by either severe or partial deficiency of hexosaminidase A.

gangliotetraose *symbol*: Gg₄ or GgOse₄; a *trivial name* for the tetrasaccharide Gal(β 1-3)GalNAc(β 1-4)Gal(β 1-4)Glc.

gangliotriose *symbol*: Gg₃ or GgOse₃; a *trivial name* for the trisaccharide GalNAc(β 1-4)Gal(β 1-4)Glc.

GaOse₂ *symbol* for galabiose (alternative to G_{A2}).

GaOse₃ *symbol* for galatriaose (alternative to G_{A3}).

gap 1 a space introduced into the written form of a sequence of residues in a biopolymer to bring part of that sequence into register with a similar region of sequence in another polymer; typically used to effect protein or nucleotide sequence alignment. **2** a discontinuity in one of the two strands of duplex DNA resulting from enzymic elimination of one or more nucleotide residues. *Compare* **nick**.

GAP *abbr.* for **1** GnRH-associated peptide (*see* **gonadotropin-releasing hormone**). **2** *abbr.* for GTPase activating protein; a protein that activates the hydrolysis of GTP bound to certain monomeric proteins,

especially p21^{ras} (Ras, *see* **RAS**), but also for other Ras-related proteins, e.g. Rho (*see* **Rho protein**) and Ran (*see* **RAN**). Since GTP-bound Ras is the active form, binding to GAP inactivates it. The protein has SH2 and SH3 domains (*see* **SH domains**) and **pleckstrin homology domains**. RGS proteins are GAPs for the α subunit of certain trimeric G-proteins.

Gap a *abbr.* for galactoprotein A (i.e. plasma **fibronectin**).

GAPDH *abbr.* for glyceraldehyde-3-phosphate dehydrogenase. It is used as an internal standard in Northern blotting and PT-PCR because its mRNA is believed to be expressed constitutively in mammalian tissues.

gap gene any of at least six genes of *Drosophila* that act early in embryogenesis to define the coarsest subdivisions of the embryo. Mutations in these genes result in gaps in the segmentation pattern; the **Krüppel** and **hunchback** proteins are products of gap genes.

gap junction *or* **nexus** any specialized area of the plasma membranes of apposed vertebrate cells where the membranes are 2–4 nm apart and penetrated by a **connexon** that bridges the extracellular space and provides open means of communication between the cytoplasm of one cell and that of the other cell. *Compare* **tight junction**.

Gap1p *abbr.* for general amino acid permease protein 1; a membrane protein of *Saccharomyces cerevisiae* that permits uptake of amino acids. It is induced by nitrogen starvation. If the yeasts are given a nitrogen-rich source, Gap1p is targeted for degradation by polyubiquitination and its synthesis is repressed.

gap penalty a numerical cost for inserting a gap in a sequence alignment. Depending on the alignment algorithm used, there may be a single gap penalty, or an **affine gap penalty** containing separate costs for initiating and extending the gap. With affine gap penalties the extension penalty is usually much lower than the insertion penalty. This penalizes gap insertions while recognizing that, where insertions exist, they often span more than one residue (hence it costs more to open a gap than it does to extend it once the gap has been opened).

gap phase either of the two phases, designated G₁ and G₂, in the cell-division cycle during **interphase** in growing eukaryotic cells during which there is no DNA synthesis.

gap repair the process of repair of a **gap** (def. 2) in one strand of a duplex DNA molecule.

garosamine 3-deoxy-4-C-methyl-3-(methylamino)-L-arabinose; a component of **gentamicins**.

gas a substance whose physical state is such that it always occupies the whole of the space in which it is contained, irrespective of the amount present. *See also* **gas laws**; **ideal gas**.

gas chromatography *abbr.*: GC; any form of chromatography in which the mobile phase is a gas. The term commonly refers to **gas–liquid (partition) chromatography** in which the stationary phase is a liquid, normally deposited on a solid support in a coiled column of glass or stainless steel, or the wall of a capillary column, but it also includes **gas–solid chromatography**, in which the stationary phase is a solid. The column is normally heated in an oven.

gas chromatography/mass spectrometry *abbr.*: GC/MS; an analytical technique that combines the separation process of **gas chromatography** with the highly selective detection technique of **mass spectrometry**.

gas constant *symbol*: *R*; a fundamental physicochemical constant; $R = 8.314\,471 \pm 0.000\,014\text{ JK}^{-1}\text{mol}^{-1}$.

gas exchange (*in physiology*) the exchange of gases between an organism and its environment. It includes oxygen uptake and carbon dioxide elimination in the respiration of all aerobic organisms, including plants, and carbon dioxide uptake and oxygen release in photosynthetic processes.

gas flow counter any gas-filled radiation detector in which the gas filling is renewed continuously. It may be operated in either the Geiger or the proportional regions of the voltage–current curve. Such devices are especially useful for detection and counting of alpha and soft-beta emitters, as no window is present to absorb the radiation.

gas laws either of two laws describing the effects of changes in pressure, *p*, and thermodynamic temperature, *T*, on the volume, *V*, of an ideal gas. **Boyle's law** (*or* **Mariotte's law**) states that at constant temperature the volume of a given mass of gas is inversely propor-

tional to the pressure; i.e. $pV = a$ constant. **Charles's law** states that at constant pressure the volume of a given mass of gas is directly proportional to its thermodynamic temperature; i.e. $V/T = a$ constant. These two laws may be combined in the expression: $pV \propto T$, or, for one mole of gas: $pV = RT$, where R is the **gas constant**.

gas-liquid (partition) chromatography an analytical method based on the partition chromatographic separation of the components of a mixture through the use of a stationary liquid phase held in place on a solid support and a mobile gas phase flowing over the liquid phase in a controlled manner. Typically, the column is heated to temperatures in the range 50–300°C and the technique is applicable to compounds that partition appreciably into the vapour phase in that range. Detection of the eluents is commonly by a **flame ionization detector**.

GASP *abbr.* for genome annotation assessment project; *see* **critical assessment competition**.

gas-solid chromatography *see* **gas chromatography**.

gastr+ a variant form of **gastro+** (before a vowel).

gastric of, pertaining to, or derived from the stomach.

gastric acid the hydrochloric acid that is secreted from parietal (or oxyntic) cells of the wall of the stomach and forms part of the **gastric juice**.

gastric inhibitory peptide *abbr.*: GIP; *or* **glucose-dependent insulinotropic peptide** *or* **glucose-dependent insulin-releasing peptide** a 42-residue polypeptide hormone produced by the K cells of the proximal small intestine in response to glucose in the intestine. It is structurally related to glucagon, secretin, and vasoactive intestinal polypeptide having the sequence (human) YAEGTFISDYSIAMD-KIHQQDFVNWLLAQKGGKNDWKHNITQ, porcine being similar but with Arg¹⁸ and Ser³⁴. It inhibits gastric secretion and motility (**enterogastrone effect**), and stimulates insulin release when administered during hyperglycemia (**insulinotropic effect**); in the latter action GIP may be synonymous with **incretin**.

gastric inhibitory peptide receptor *abbr.*: GIP receptor; any of the G-protein-associated membrane receptors that bind **gastric inhibitory peptide** (GIP) and activate adenylate cyclase. The rat protein consists of 455 amino acids (52.26 kDa), of which residues 1–18 are the signal peptide, and 19–455 are the receptor.

gastric juice the thin, clear, acidic fluid secreted by glands of the stomach mucosa in response to the ingestion of food. It contains mucus, intrinsic factor, hydrochloric acid (about 155 mm in humans) from the parietal cells, and **pepsinogen**, the precursor of pepsin proteolytic enzymes.

gastricsin EC 3.4.23.3; *other names*: pepsin C, pig parapepsin II; an enzyme of the pepsin family that appears to be present in the gastric juice of most vertebrates. It effects preferential cleavage at Tyr-|Xaa bonds. It is a single-chain phosphoprotein formed by limited proteolysis of pepsinogen C with a more restricted specificity than pepsin A but high activity towards hemoglobin.

gastrin any of various members of a group of interrelated peptide hormones from the **G cells** of the pyloric antral mucosa of the stomach, and of the proximal duodenum, that strongly stimulate acid secretion by the stomach mucosa. There are three principal, biologically active forms: **big gastrin** (*or* G-34); **little gastrin**, (*or* G-17 *or* gastrin I); and **mini gastrin** (*or* G-14); these have 34, 17, and 14 amino-acid residues, respectively. The sequence of human big gastrin (gastrin I in parentheses, but with pE for the terminal Q) is

where pE indicates pyroglutamyl. Each has a counterpart, e.g. G-17S (*or* gastrin II), in which the tyrosyl residue is sulfated. There are other, larger immunoreactive forms, known as **big-big gastrins**, that elute from a gel column before G-34. The entire physiological activity is possessed by the C-terminal tetrapeptide amide sequence that ends in a phenylalaninamide residue. The C-terminal pentapeptide sequence of gastrin is the same as that of **cholecystokinin** and **cerulein**. *See also* **gastrinoma**, **pentagastrin**, **Zollinger-Ellison syndrome**.

gastrinoma a tumour of the gastrin-producing **G cells** of the pancreas, stomach, or duodenum. Gastrinomas are associated with high gastrin levels in the circulating blood, gastric hypersecretion,

and fulminant gastroduodenal ulcerations (**Zollinger-Ellison syndrome**).

gastrin receptor *see* **cholecystokinin receptor**.

gastrin-releasing protein a growth factor secreted by some small-cell lung cancers.

gastro+ *or* (*often before a vowel*) **gastr+** *comb. form* meaning stomach. [From Greek *gastēr*, belly.]

gastroenteric an alternative term for **gastrointestinal**.

gastrointestinal *or* **gastroenteric** of, or pertaining to, the stomach and intestines.

gastrointestinal hormone any member of a diverse group of peptides with hormone or hormone-like actions that occur in specific cells of the gastrointestinal tract, the pancreatic islets, and other locations. The best characterized include **cholecystokinin**, **gastric inhibitory polypeptide**, **gastrin**, **glucagon**, **insulin**, **motilin**, **neurotensin**, **pancreatic polypeptide**, **secretin**, **substance P**, and **vasoactive intestinal polypeptide**. *See also* **gut hormone**.

gastrula an early stage of development of an animal embryo, following the blastula, in which the cells are invaginating to form the rudiment of a gut cavity.

gas vacuole any membrane-bound, gas-containing, intracellular organelle. Gas vacuoles provide aquatic prokaryotes with buoyancy. *See also* **gas vesicle**.

gas vesicle the submicroscopic component of the gas vacuole in certain aquatic prokaryotes, especially cyanobacteria. It is constructed of molecules of a single protein (≈ 15 kDa), which form a monolayer enclosing a hollow space into which gases diffuse. Typically it is cylindrical with conical ends, 3–300 nm in diameter and 300–1000 nm in length.

GATA-1 *or* **ERYFI** *or* **GF-1** *or* **NF-E1** a transcriptional activator protein that serves as a general switch factor for erythroid development. It binds to DNA sites with the consensus sequence [A/T]GATA[A/G] within regulatory regions of globin genes and other genes expressed in erythroid cells. Other transcription factors with similar sequences are termed **GATA-type**. GATA-1 binds the zinc finger-rich transcription regulator FOG-1.

GATase *see* **glutamine amidotransferase**.

gate (*in electronics*) **1** a logic circuit that gives an output signal only in response to a combination of two or more input signals. **2** a signal that allows or controls the passage of another signal.

gated channel a channel in the membrane of a cell (especially an excitable cell) that allows entry of ions into the cell only under specific conditions. *See also* **ligand-gated**, **voltage-gated ion channel**.

gating the opening and closing of a gated channel.

gating current an electric current arising from the movement of charged groups in the protein of the sodium-ion channels of excitable nerve membranes, during the passage of an action potential, prior to the opening of the channel.

g-atom *abbr.* for gram-atom or gram-atomic weight.

GAU a codon in mRNA for L-aspartic acid.

gauche *abbr.*: *g*; (*in chemical nomenclature*) a conformational descriptor indicating a synclinal conformation. *See* **conformation**.

Gaucher activator *or* **saposin C**; a glycosylated polypeptide derived by appropriate proteolytic cleavage of prosaposin. It is an activator of lysosomal **glucosylceramidase**. Deficiency of prosaposin or saposin C, due to mutation in the prosaposin gene, produces a variant of Gaucher's disease type 3. *See* **saposin**.

Gaucher's disease an autosomal recessive lysosomal storage disease characterized by **glucosylceramide** accumulation, especially in macrophages in spleen, bone marrow, and liver, with splenomegaly and bone lesions. Type 1 is the commonest, does not affect the nervous system (i.e. is non-neuronopathic), and is frequently diagnosed in adulthood. Type 2 is acute, neuronopathic, and usually fatal in the first two years of life. Type 3 is subacute, neuronopathic, and associated with mental retardation. Numerous mutations in the gene at 1q31 result in various degrees of deficiency of **glucosylceramidase** (EC 3.2.1.45). Prosaposin or saposin C deficiency produces variants of the disease. *See also* **saposin**. [After Philippe Charles Ernest Gaucher (1854–1918), French physician.]

gauss *symbol*: G *or* Gs; the cgs unit of magnetic flux; it is equal to a magnetic flux density of one maxwell per cm², one line of magnetic

induction per cm², or 10⁻⁴ tesla. It is not accepted for use with the SI.

GAUSSIAN a computer program, based on quantum mechanics, which calculates the energies, structures, and vibrational frequencies of molecules.

Gaussian distribution *an alternative name for normal distribution.*

gavage the administration of food or other material in liquid form through a tube directly into the stomach; forced feeding in this manner.

Gb₃ *symbol for globotriaose (alternative to GbOse₃).*

Gb₄ *symbol for globotetraose (alternative to GbOse₄).*

G-banding or **Giemsa banding** a commonly used procedure in which **Giemsa's stain** is used to identify chromosomal bands in a karyotype.

GbOse₃ *symbol for globotriaose (alternative to Gb₃).*

GbOse₄ *symbol for globotetraose (alternative to Gb₄).*

GBP *abbr. for glucose bisphosphate (formerly called glucose diphosphate).*

G-1,6-BP *abbr. for glucose 1,6-bisphosphate (formerly called glucose 1,6-diphosphate).*

Gc *symbol for the glycoloyl group.*

GC *abbr. for gas chromatography.*

GCA a codon in mRNA for L-alanine.

GCAP *abbr. for guanylate cyclase activator protein; either of two Ca²⁺-binding proteins (GCAP-1 and GCAP-2) of the calmodulin family that bind and activate retinal guanylyl cyclase protein (see RETGC) in the membrane of retinal cone cells.*

GC box a nucleotide sequence element common in eukaryotic promoters: consensus GGGCGC.

GCC a codon in mRNA for L-alanine.

G cell a gastrin-producing cell found in the antrum of the stomach and to a lesser extent in the mucosa of the duodenum, though the distribution varies in different species. In humans, G cells are small and pyriform while in dogs they are larger and triangular in shape. They can be identified by immunofluorescence using a gastrin-specific antibody.

GC_G 1 a codon in mRNA for L-alanine. **2** *abbr. for Genetics Computer Group; see sequence analysis package.*

GC/MS *abbr. for gas chromatography/mass spectrometry.*

GCN4 a gene for a yeast transcription factor that binds, as a dimer, to the sequence TGA[C/G]TCA. The protein has a **leucine zipper**, and resembles **FOS** and **JUN**.

GCRDB *abbr. for G protein-coupled receptor database; see specialist database.*

G-CSF *abbr. for granulocyte colony stimulating factor.*

GCU a codon in mRNA for L-alanine.

Gd *symbol for gadolinium.*

GDC *abbr. for Graves' disease carrier protein; it is similar in structure and some other properties to ADP,ATP carrier protein.*

G4 DNA *abbr. for DNA containing a G-quartet.*

GDNF *abbr. for glial cell line-derived neurotrophic factor; a glycosylated, disulfide-bonded homodimer that promotes survival and morphological differentiation of dopaminergic neurons. Human and rat GDNFs share 93% similarity. Compare brain-derived neurotrophic factor.*

GDP *abbr. for 1* guanosine diphosphate. **2** glucose diphosphate (now called glucose bisphosphate).

G-1,6-DP *abbr. for glucose 1,6-diphosphate (now called glucose 1,6-bisphosphate).*

GDP-fucosepyrophosphorylase *see fucose-1-phosphate guanylyltransferase.*

GDPM or **GDPmannose** *abbr. for guanosinediphosphomannose.*

GDPmannose 6-dehydrogenase EC 1.1.1.132; an enzyme that catalyses the reaction between GDP-D-mannose, 2 NAD⁺ and H₂O to form GDP-D-mannuronate and 2 NADH. Example from *Pseudomonas aeruginosa*: ALGD_PSEAE, 436 amino acids (47.58 kDa).

GDPmannose 3,5-epimerase EC 5.1.3.18; an enzyme that catalyses the interconversion of GDP-D-mannose and GDP-L-galactose.

GDS (*in clinical chemistry*) *abbr. for guanine deaminase.*

Ge *symbol for germanium.*

Geiger counter or **Geiger-Müller counter** a device for detecting and measuring ionizing radiation (alpha or beta particles or gamma-ray

photons). It consists of a glass envelope containing low-pressure gas and an anode and a cathode, between which a large electric-potential difference is maintained. The ions produced in the gas by the incoming ionizing radiation are accelerated towards their appropriate electrodes, causing a momentary drop in the potential between the latter. The voltage pulses so produced may be counted with a suitable electronic circuit. [After Hans Wilhelm Geiger (1882–1945), German physicist, and Erwin Wilhelm Müller (1911–77), German-born US physicist.]

Geiger region or **Geiger-Müller region** the part of the curve of applied voltage against number of ions collected for a given incoming radiation by a **Geiger counter**, where all possible ion-pairs, both primary and secondary, are collected; i.e. the signal is relatively independent of the applied voltage. *Compare proportional region.*

Gek *abbr. for Genghis Khan.*

gel 1 a colloidal system, with the semblance of a solid, in which a solid is dispersed in a liquid. A gel has a finite, usually rather small, yield stress. **2** to become, or cause to become, a gel.

gelatin a heterogeneous mixture of water-soluble proteins of high average *M_r*, derived from collagen by partial hydrolysis in either acid (type A) or alkali (type B). Collagen obtained by boiling skins, ligaments, tendons, etc. with water is also termed gelatin, as also is collagen denatured by heating for 15 minutes at 45 °C, used as a substrate for **gelatinase**. It is colourless, or slightly yellow, and transparent, and occurs as brittle sheets, flakes, or coarse powder; these swell in water to form gels below 35–40 °C, containing 5–10 times as much water as gelatin by weight. Nutritionally, gelatin is an incomplete protein, containing only small amounts of certain essential amino acids, especially tryptophan. It is widely used in foods, and in the manufacture of adhesives, photographic films and plates, and light filters.

gelatinase EC 3.4.24.24; *recommended name*: gelatinase A; *other names*: 72 kDa gelatinase; matrix metalloproteinase 2; type IV collagenase. An enzyme that catalyses the cleavage of **gelatin** and collagen types IV, V, VII, and X; it cleaves the collagen-like substrate sequence Pro-Gln-Gly-|-Ile-Ala-Gly-Gln; zinc and calcium are cofactors. It is a metallo (zinc) endopeptidase with **fibronectin** domains, and is produced by fibroblasts. The human precursor (660 amino acids) has a large pre-pro region; the enzyme starts at amino acid 110.

gelation 1 the (usually reversible) act or process of forming a **gel** (def. 1) from a **sol**. *Compare solution.* **2** the solidification of a liquid by cold. —**gelate** *vb*.

gel chromatography *see liquid-gel chromatography.*

gel diffusion (*in immunology*) a technique in which antibodies and antigens are allowed to diffuse independently through a gel, often of agar, and form a precipitate within the gel where homologous antigens and antibodies meet in optimal proportions.

gel electrophoresis a type of **zone electrophoresis** in which the supporting medium is a gel of uniform concentration, commonly of polyacrylamide, agarose, or starch. *See polyacrylamide (gel) electrophoresis.* *Compare gradient (acrylamide) gel electrophoresis.*

gel filtration or **gel-filtration chromatography** *see gel-permeation chromatography.*

gel-filtration chromatography *see gel-permeation chromatography.*

gel-filtration high-performance liquid chromatography a technique of **gel-permeation chromatography** that uses a support material of high mechanical strength and chemical inertness thereby enabling separations to be effected under the conditions, and with the advantages of **high-pressure liquid chromatography**.

gel fluorography the application of **fluorography** (def. 2) to the detection of substances separated in gels, as by gel electrophoresis.

gellify to cause to become a **gel** (def. 1); to become gel-like; to **gel** (def. 2).

gelonin or **ribosome-inactivating protein** or **rRNA N-glycosidase** EC 3.2.2.22; *recommended name*: rRNA N-glycosidase; an extremely stable, potent toxin extracted from seeds of *Gelonium multiflorum* (a plant of the spurge family). It is a glycoprotein of 28–30 kDa containing terminal mannose residues. It acts as a powerful inhibitor of protein synthesis in cell-free systems but not in intact cells; it inactivates the 60S ribosomal subunit but not the 40S subunit. It hydrolyses a specific N-glycosidic bond of an adenosine on the 28S

rRNA. in cell-free protein-synthesizing systems gelonin acts like the A chains of **abrin**, **ricin**, and **modeccin**, suggesting that it lacks the ability to bind to cell surfaces and enter cells.

gel-permeation chromatography a method for the separation of substances in solution, *commonly known as gel filtration or gel-filtration chromatography*. The separation is based mainly on exclusion effects, such as differences in molecular size and/or shape or in charge, when the stationary phase is a swollen gel. The gel used is commonly a water-swollen insoluble carbohydrate polymer from which macromolecules are excluded and migrate without retention in the interstitial fluid. Substances of low or intermediate relative molecular mass penetrate into the gel particles to an extent that is, in most instances, determined by their molecular dimensions and the degree of cross-linking of the gel. The larger molecules therefore pass through the bed more rapidly than smaller molecules. The technique can be used to determine the relative molecular mass (M_r) of unknown materials, since, for a particular column, elution occurs at a volume determined by the equation

$$V_R/V_0 = 1 - \rho \log(M_r/M_{r0})$$

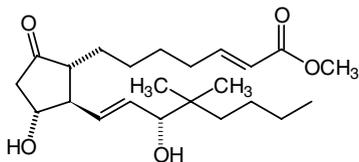

where V_R is the elution volume of the unknown, V_0 is the volume of the mobile phase in the column, M_r is the M_r of the unknown, M_{r0} is the M_r of the largest totally permeating molecule, and ρ is a factor that is a property of the column. Thus each column must be calibrated using standard proteins, and a plot made of the elution volumes against $\log M_r$ of the standards, from which the unknown M_r can be determined.

gel retardation assay *an alternative name for electrophoretic mobility shift assay*.

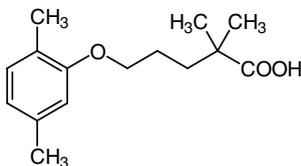

gelsolin a heat-labile, monomeric protein, of apparent M_r 90 000, isolated from macrophages, platelets, and plasma. It appears to promote the gel-sol transformation of **actin**, and may thereby be important in the control of locomotion, secretion, and endocytosis in these and other cells; β -actin has a similar action. There are two forms of gelsolin, plasma and cytoplasmic, generated by alternative splicing. The cytoplasmic, calcium-regulated, actin-modulating form binds to the barbed ends of actin monomers or filaments, preventing monomer exchange; it also promotes nucleation, and binds with high affinity to fibronectin.

gem- *prefix (in chemical nomenclature) denoting the presence of geminal substituents*.

gemeprost 16,16-dimethyl-*trans*- Δ^2 -prostaglandin E_1 methyl ester; 11,15-dihydroxy-16,16-dimethyl-9-oxoprostanoic acid methyl ester; an analogue of **prostaglandin** E_1 with uterine stimulant activity.

gemfibrozil 2,2-dimethyl-5-(2,5-xylyloxy)valeric acid; an antihyperlipoproteinemic agent with actions similar to **clofibrate**.

gemin 3 a mammalian DEAD-box helicase associated with the SMN (survival of motor neuron) complex. Gemin 3, gemin 4, eIF2C2, and miRNA are present in this 15S ribonucleoprotein complex. This may be a mammalian RNA-induced silencing complex (RISC).

geminal (*in chemistry*) describing two like groups or atoms attached to the same atom in a molecule, i.e. the geminal groups or atoms are separated by two bonds attached to the same atom. The presence of geminal substituents is denoted by the prefix *gem-* attached to the name of the compound. *Compare vicinal* (def. 2).

geminate occurring in pairs; doubled, twin.

geminin a protein (35 kDa) of metazoan animals that is present in the cell nucleus from the S phase of the cell cycle to mitosis, being degraded on completion of mitosis. It binds and inhibits two proteins (65 kDa and 130 kDa) that are required for initiation of DNA replication.

geminivirus a plant virus in which the virion morphology is characterized by the possession of a pair of isometric particles, each containing circular or linear single-stranded DNA. Transmission occurs largely via leafhoppers or whitefly, but sometimes transmission is effected mechanically. Some geminiviruses cause economically important diseases in cultivated plants. [From Latin *geminus*, twins.]

+gen or (*after a consonant*) **+ogen comb. form** signifying producing or capable of producing (either directly or indirectly). In biological sciences it is used especially (1) with word-stems relating to physiological or pathological processes, states, conditions, etc., to denote a causative agent (e.g. antigen, lactogen, mutagen, estrogen); (2) with names of certain proteinases or blood components, to denote their inactive precursors or substances from which they can be derived by enzymic action (e.g. angiotensinogen, caseinogen, fibrinogen, trypsinogen) (*see also pro-* (def. 3), **zymogen**); (3) with names or name-roots of certain metabolites, to denote either a storage substance (e.g. glycogen, phosphagen) or a biosynthetic precursor (e.g. porphobilinogen); (4) with word-stems relating to physical properties (e.g. chromogen, luminogen). — **+genic** or **+genous** *adj. suffix*.

Genaminox KC *the proprietary name for detergents similar to lauryldimethylamine oxide, but with different alkyl chain lengths* (9–13).

Genapol *the proprietary name for a series of nonionic polyoxyethylene detergents of the general formula* $\text{CH}_3(\text{CH}_2)_x - \text{O}(\text{CH}_2\text{CH}_2\text{O})_y - \text{H}$; Genapol X-080 has $x = 12$, $y = 8$, CMC 0.06–0.15 mm; Genapol X-100 has $x = 12$, $y = 10$, aggregation number 88, CMC 0.15 mm. *Compare C_xE_y, Lubrol, Triton, Tween*.

GenBank *see sequence database*.

gene in classical genetics, a statistical entity that correlates with a particular phenotypic characteristic; the functional unit of heredity. Before their biochemical nature was understood, genes were defined in terms of units of mutation and/or recombination. Discovery of the role of DNA in genetic processes, followed by elaboration of the **central dogma** of protein synthesis, led to enunciation of the ‘one gene–one enzyme’ hypothesis, i.e. that a gene consisted of DNA that coded for a protein that performed the functions associated with the phenotypic expression of the gene. In current molecular genetics, the concept requires modification in a number of ways. First, the genomic DNA that codes for a polypeptide is associated with regulatory sequences such as promoters. Second, the polypeptide resulting from translation of mRNA may be subsequently split to give several polypeptides with different functions (*see polyprotein*). Third, the RNA transcribed may give rise to several different proteins as a result of **alternative splicing**. Three types of genes are now distinguished: those that are both transcribed into mRNA and translated into polypeptides (**structural genes**); those that are only transcribed into RNA (e.g. rRNA, tRNA); and those that function as regulators of the expression of the other two types (**regulator genes**). In diploid organisms a gene may occur in alternative forms (**alleles**). The term gene is sometimes used interchangeably with **cistron**.

gene amplification the selective, repeated replication of a certain gene or genes without a proportional increase in other genes in the genome. It occurs, e.g., in the DNA puffs of *Rhynchosciara* and some other flies and in the genes encoding ribosomal RNA (so-called ribosomal DNA) in amphibian oocytes. The mammalian dihydrofolate reductase gene is amplified in cells selected for resistance to increasing concentrations of methotrexate.

gene bank *an alternative name for gene library*.

GeneChip array a standardized, reproducible, proprietary technology for simultaneous measurement of the expression levels of large

numbers of genes. The method involves *in situ* synthesis of DNA oligonucleotide probes on glass slides by means of photolithography, which allows several hundred thousand spots (with copies of specific DNA sequences) to be placed on a single slide. Single mRNA samples are then fluorescently labelled and hybridized to the chip, scanned with a fluorescent scanner, and the data collected and automatically analysed to quantify the relative amount of fluorescence and hence the relative levels of expression of each gene. *See also* **microarray**.

gene cloning *see* **molecular cloning**.

gene cluster *or* **gene complex** any group of two or more functionally related genes that are closely linked on a chromosome. The genes of a gene cluster are often structural genes coding for the enzymes that catalyse the various steps of a metabolic pathway.

gene complex *an alternative name for* **gene cluster**.

gene conversion a genetic event involving transfer of DNA between genes, usually as a result of unequal crossing over during meiosis. If the transferred material contains mutations, or if it disrupts the coding sequence of the gene, it may be a mechanism for mutation.

gene desert a region of a chromosome that contains few if any genes.

gene dosage the number of times a particular gene is present in the genome.

gene duplication the phenomenon, occurring in some higher organisms, in which there is duplication of the DNA sequences representing particular genes. This process is thought to have played a decisive part in the evolution of these organisms, through the occurrence of different mutations in the two duplicated genes.

gene expression the process by which the information carried by a gene or genes becomes manifest as the phenotype. It involves **transcription** of the gene into complementary RNA sequences and, for structural genes, subsequent **translation** of mRNA into polypeptide chains and their assembly into the ultimate protein products. Gene expression is tightly regulated by **promoters**, **enhancers**, and **transcription factors**.

gene expression array *see* **microarray**.

gene expression profile a characteristic pattern or inventory of gene expression from particular cell types, organs, or tissues, under particular physiological or disease conditions. Methods for analysing expression profiles depend on the technology used to measure expression intensities, but are usually classed as sequence tag counting – e.g. expressed sequence tags (ESTs), SAGE – or hybridization methods (e.g. microarrays).

gene family a group of closely related genes that encode similar protein products. Such genes tend to arise by duplication of an ancestral gene, and subsequently evolve independently via random mutational events. This results in independent genes, either clustered together on a chromosome or dispersed throughout the genome, that encode proteins with slightly different functions.

gene frequency a measure of the proportion of an allele in a given population, equal to the number of loci at which a given allele occurs, divided by the total number of loci at which it could occur.

gene fusion *or* **translational fusion** *or* **protein fusion** the joining of DNA from two genes as a result of translocation or inversion. It may give rise either to a chimeric protein product or to the misregulation of transcription of one gene by the *cis*-regulatory elements of the other.

gene identification *an alternative term for* **gene prediction**.

gene jungle a region of a chromosome that has a high gene density.

gene library *or* **cloned library** *or* **gene bank** *or* **shotgun collection** a random collection of DNA fragments cloned in a **vector** (def. 3), and which may include all the genetic information of a particular species. It may be prepared from a variety of sources, including an extract of mRNA, in contrast to a **genomic library** which is prepared from genomic DNA.

gene mutation any **mutation** (def. 1) occurring within a single gene.

gene ontology *abbr.*: GO; a controlled vocabulary (based on model eukaryotic organisms, including *Drosophila melanogaster*, *Saccharomyces cerevisiae*, *Mus musculus*, etc.) that has been developed on a community-wide basis to relate gene and protein names, functional groupings of genes and gene products, and location of action

of these entities, into a coherent, standardized whole. The three organizing principles of GO are molecular function, biological process, and cellular component.

gene pool the sum of the genetic information in the reproductive members of a population of sexually reproducing organisms.

gene prediction *or* **gene identification** the prediction of genes in an uncharacterized nucleotide sequence based on its similarity to known gene sequences. *Compare* **ab initio gene prediction**.

gene product any of the types of RNA (transcription products) or any of the proteins or protein subunits (translation products) synthesized biochemically on the basis of the information encoded in a genome.

general acid-catalysis homogeneous catalysis in which the catalysts are various hydron donors (acids). *Compare* **specific acid-catalysis**.

general base-catalysis homogeneous catalysis in which the catalysts are various hydron acceptors (bases). *Compare* **specific base-catalysis**.

generally labelled describing the labelling of a molecule in such a way that a radionuclide may be present at any or all (but not necessarily all) possible positions. *Compare* **uniformly labelled**.

general transcription factor any of the proteins whose assembly around the **TATA box** is required for the initiation of transcription of most eukaryotic genes. Their activity is enhanced by transcription activators that bind at distal enhancer sites. *See* **promoter**.

generate (*in mathematics*) to conceive a point, line, or surface to be moving in a specified way so as to form a line, surface, or solid, respectively.

generation 1 the act or process of producing or reproducing, naturally or artificially. **2** the phase in a life cycle that extends from one to the immediately successive reproduction. **3** any group comprising all those members of a population who are equally removed from a common ancestor or from coeval ancestors.

generation of diversity (*in immunology*) the process by which a large number of variable regions are generated in the immunoglobulins. The **stem cell** genome contains multiple variants of L-chain V (variable) and J genes and of the H-chain V, J, and D (diversity) genes. As the stem cells differentiate, the maturing lymphocyte constructs particular L and H genes of virtually unique structure by a recombination process that randomly selects one out of each set of gene segments and assembles them, together with a C (for the constant region) gene into a mature H or L gene. This, combined with recombination inaccuracies, somatic point mutations, and the varied combinations of l and h chains found in immunoglobulins results in a repertoire of millions of lymphocytes each with H and L genes encoding unique molecules. *See also* **immunoglobulin**.

generation time the time between division of a cell and that of its daughter cells, averaged over a whole cell population.

gene redundancy the presence in a cell of many copies of a single gene. The multiple copies may be inherited or result from selective **gene duplication** during development.

gene-regulatory protein any protein that binds to a specific DNA sequence to alter the expression of a gene.

+genesis *comb. form* denoting beginning or origin; development; generation. *See also* **+gen.** —**+genetic** *or* **+genic** *adj. comb. form*.

gene splicing biochemical and/or chemical manipulations with the object of attaching one DNA molecule to another. The nearest method is to cleave the DNA to be inserted (foreign DNA) with a **restriction endonuclease** that yields single-stranded ends that are complementary to each other. The **cloning vector** into which the foreign DNA is to be inserted is treated with the same endonuclease so that the complementary ends of the two DNAs specifically associate under annealing conditions and are subsequently covalently joined (spliced) through the action of **DNA ligase**. If the endonuclease produces fragments with 'blunt' or **flush ends** then a similar procedure is adopted. If the foreign DNA and the cloning vector have no common restriction sites then terminal **deoxynucleotidyl transferase** may be used which adds nucleotides to the 3'-terminal OH group of a DNA chain. For this purpose tails of poly(dT) and poly(dA) may be used. The transformed cells are then grown and those containing the spliced DNA are selected (cloning). The preferred method of splicing is one that allows the foreign DNA to be removed easily by means of a restriction endonuclease, preferably

the same one that was initially used in splicing. By this means large amounts of the foreign DNA can be synthesized and used for many different purposes. Alternatively the cloned cells containing the foreign DNA can be used to permit the expression of a foreign protein which is then recovered.

gene therapy the treatment of disease by incorporating into a person's genome DNA that encodes a specific therapeutic protein or that corrects deficiency of a normal protein due to a gene mutation.

genetic or **genetical** of or pertaining to **genetics**, **genes**, or the origin of something. —**genetically** *adv.*

genetic ablation a method applied in transgenic organisms in which a tissue-specific promoter is used to enable the expression of a gene for a toxin, such as diphtheria toxin A (*dipA*), to cause destruction of the particular tissue during development.

genetic algorithm an algorithm that exploits evolutionary principles. Given an initial population of solutions, a genetic algorithm evaluates which have the best fit to some desired property as measured by a fitness function. More optimal solutions are then generated by a heuristic process that mimics genetic selection, employing, for example, crossover, mutation, and replication over a number of generations.

genetically engineered describing a cell, strain, or organism whose phenotype has been altered by manipulation of its genetic material. *See* **genetic engineering**.

genetically modified organism *abbr.*: GMO; an organism that has been modified by the addition (from the same or different species) or deletion of genetic material, or by some other genetic alteration, to enhance a natural characteristic or to provide one that it does not have naturally.

genetic block a reduction in the activity of a particular enzyme in a metabolic pathway as a result of gene mutation. A genetic block is termed **complete** when the particular enzyme activity is absent, or **incomplete** (or **leaky**) when the enzyme formed is defective and of limited activity.

genetic carrier *see* **carrier** (def. 9).

genetic code all the regularities in nucleotide sequence according to which genetic information for the sequences of all the polypeptides synthesized by transcription and translation is encoded in DNA (or RNA in some viruses). A sequence of three nucleotide residues (a codon) is required to code for one amino-acid residue, and since there are four different kinds of base in nucleic acids (apart from minor constituents), 4³ i.e. 64 different nucleotide triplets can exist. But only 20 different amino-acid residues in polypeptides can be coded for; therefore the code is degenerate in that most amino acids can be specified by more than one codon. In terms of the sequence of nucleotides in mRNA, i.e. the nucleotides complementary to those in the genetic material, the genetic code, reading from the 5' end to the 3' end of each codon, is given in the table. (The letter A symbolizes a nucleotide residue containing adenine; G, guanine; C, cytosine; and U, uracil; each amino-acid residue is represented by its usual three-letter symbol.)

UUU: Phe	UCU: Ser	UAU: Tyr	UGU: Cys
UUC: Phe	UCC: Ser	UAC: Tyr	UGC: Cys
UUA: Leu	UCA: Ser	UAA: Ter†	UGA: Ter‡
UUG: Leu	UCG: Ser	UAG: Ter‡	UGG: Trp
CUU: Leu	CCU: Pro	CAU: His	CGU: Arg
CUC: Leu	CCC: Pro	CAC: His	CGC: Arg
CUA: Leu	CCA: Pro	CAA: Gln	CGA: Arg
CUG: Leu	CCG: Pro	CAG: Gln	CGG: Arg
AUU: Ile	ACU: Thr	AAU: Asn	AGU: Ser
AUC: Ile	ACC: Thr	AAC: Asn	AGC: Ser
AUA: Ile	ACA: Thr	AAA: Lys	AGA: Arg
AUG: Met‡	ACG: Thr	AAG: Lys	AGG: Arg
GUU: Val	GCU: Ala	GAU: Asp	GGU: Gly
GUC: Val	GCC: Ala	GAC: Asp	GGC: Gly
GUA: Val	GCA: Ala	GAA: Glu	GGA: Gly
GUG: Val	GCG: Ala	GAG: Glu	GGG: Gly

† termination codon. UAA was once called **ochre codon**; UAG, **amber codon**; UGA, **opal codon**.

‡ initiation codon. The methionine codon AUG is the most common starting point of translation of a genetic message but GUG sometimes serves.

The genetic code is almost universal but differences have been found in the DNA of mitochondria from a number of organisms. For example, in human mitochondria UGA codes for Trp and not for termination; AUA codes for Met and not for Ile; AGA and AGG are termination codons and do not code for Arg; AUA and possibly AUU act as initiation codons as well as AUG.

genetic colonization the introduction by a parasite of genetic information into a host such as to cause the host to synthesize products that only the parasite can use. This occurs in some plants, e.g., in cases of parasitism by *Agrobacterium* spp.

genetic complementation the phenomenon whereby two different mutations produce a wild-type phenotype in a double heterozygote. It thus provides evidence that the mutations do not affect the same gene.

genetic cross 1 any mating of two organisms that results in a **genetic recombinant**. **2** the offspring of two (or more) parent organisms produced by mating or other means.

genetic defect any alteration in the genetic information carried in an individual organism, the effect of which is to produce a phenotype that is at a disadvantage in competing with a normal organism of the same species or in meeting the challenges of its environment. *See also* **inborn error of metabolism**, **molecular disease**.

genetic disease any disease ultimately caused by a genetically determined biochemical defect. In the strict sense a genetic disease is only slightly influenced by environmental factors.

genetic drift 1 any change with time in gene frequency in a population. It may be either directed, **steady drift**, or undirected, **random drift**. **2** irregular, random fluctuations in gene frequency in a (relatively) small population caused by statistical effects.

genetic engineering the genetic manipulations used to produce individuals having a new combination of inherited properties. Such manipulation may be of two kinds: (1) cellular manipulation, involving the culturing of (haploid) cells and the hybridization of somatic cells (*see* **cell fusion**); and (2) molecular manipulation, involving the construction of artificial recombinant DNA molecules, their insertion into a **vector** (def. 3), and their establishment in a host cell or organism. The latter approach has been called **recombinant DNA technology**.

genetic erosion any natural or human-engendered process that, with time, results in loss of genetic diversity in populations of the same species, or reduction of the genetic base of a species, or loss of an entire species.

Geneticin a proprietary name for **G418**.

genetic information the information carried in a sequence of nucleotides in a molecule of DNA or RNA.

genetic locus *see* **locus**.

genetic map any diagram showing the linear order of, and the relative distances between, mutable sites on a chromosome as deduced from genetic recombination experiments.

genetic mapping any method that may be used to determine the positions of, and the relative distances between, genes of a linkage group or of sites within a gene (fine-scale mapping). In classical genetics, mapping relied on a study of recombination frequency and was measured in **morgans**. In molecular biology, mapping relies on the sequencing of DNA in a chromosome. Current work is aimed at mapping entire genomes. *See also* **genetic map**, **map unit**.

genetic marker 1 any genetically controlled phenotypic difference that can be used in analysing the genetic make-up of an organism. **2** any gene difference in either one or both alleles used in the detection of genetic recombination events.

genetic material the molecular carrier of primary genetic information that serves as a template for its own replication and provides the structural and regulatory information for the processes of protein synthesis and cell development. It consists of double-stranded DNA in higher organisms, bacteria, and most bacteriophages, sin-

gle-stranded DNA in some bacteriophages, and RNA in the RNA viruses.

genetic pollution contamination of the genetic make-up of wild populations or species with foreign genes (usually as a result of genetic engineering).

genetic polymorphism the regular and simultaneous existence in the same population of two or more discontinuous variants or genotypes, at a frequency existing in more than 1% of the population, that cannot be due to recurrent mutations. The different human blood groups are an example.

genetic profiling or **DNA fingerprinting** a technique for providing profiles of DNA fragments (resulting from digestion with restriction enzymes) that characterize a genome. The human genome is scattered with minisatellites, regions of DNA consisting of tandem repeats of short base sequence which can show extensive variation in the number of repeats, leading to multi-allelic variation and high degrees of heterozygosity. This extreme level of variation renders minisatellite or VNTR (**variable number tandem repeats**) loci invaluable as genetic markers. The DNA is digested with a suitable restriction endonuclease and the fragments are electrophoresed through agarose gel and transferred by blotting to a nylon filter. Hybridization is with a minisatellite probe labelled with ³²P. The use of the polymerase chain reaction (**PCR**) to amplify hypervariable loci, including very short tandem-repetitive microsatellites, has greatly increased the sensitivity of DNA typing systems and the ability to type degraded human DNA. The method can be used to identify an individual's DNA and also to trace the parentage of an individual. The method is not confined to humans but has been applied to a wide range of species.

genetic recombinant any organism produced by **genetic recombination**.

genetic recombination the processes by which a new genotype is formed by reassortment of genes resulting in gene combinations different from those that were present in the parents. In eukaryotes genetic recombination can occur by chromosome assortment, intrachromosomal recombination, or nonreciprocal interchromosomal recombination. Intrachromosomal recombination occurs by **crossing over**. In bacteria it may occur by genetic transformation, conjugation, transduction, or F-duction. *See also* **Holliday junction**.

genetics 1 the branch of biology concerned with heredity and variation in organisms. It embraces the phenomenology and physiology of heredity; the nature of genetic information; the storage of genetic material; the replication, mutation, transmission, and recombination of genetic material; and the way it is translated into systems that control development and metabolism, and determine the reappearance of parental characters among progeny. **2** the genetic features and constitution of any single organism, species, or group of organisms. *See also* **reverse genetics**.

genetic screening the testing of individuals or groups of individuals for some specific gene product or resulting metabolite for the purpose of identifying genetic defects or diseases.

genetic signature or **genetic fingerprint 1** the nucleotide sequences that are specific to an individual. **2** a gene expression pattern characteristic of a particular cell type. **3** a genetic trait characteristic of an ethnic group.

genetic transformation *see* **transformation** (def. 1).

genetic variance that part of the phenotypic variance caused by the varying genotypes of the individuals within a population.

gene trap vector a DNA construct incorporating a selectable marker such as *neo^R*, a promoterless reporter such as *lacZ*, and an upstream splice acceptor site. The vector is used to transfect mouse ES cells or other cells by electroporation. If the vector is integrated into a functioning gene, expression of the reporter gene will occur. Flanking DNA can be recovered and sequenced to reveal the identity of the gene. *Compare* **enhancer trap vector**.

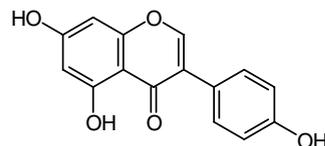

Genghis Khan *abbr.*: Gek; a protein serine/threonine kinase of *Drosophila* that is remarkably homologous to the human myotonic dystrophy protein kinase.

genic of, or relating to, a gene or genes.

genin 1 the class name for the noncarbohydrate residue of steroid glycosides. It is used as a suffix in forming trivial names of the naturally occurring glycoside precursors; e.g. digitogenin (from digi-

tonin), sapogenin (from saponin). **2** a former name for spirostan, 16,22:22,26-diepoxycholestane.

genistein 4,5,7-trihydroxyisoflavone; 5,7-dihydroxy-3-(4-hydroxyphenyl)-4H-1-benzopyran-4-one; a yellow pigment of the broom plant *Genista tinctoria*. It inhibits protein-tyrosine kinases and other protein kinases, being a competitive inhibitor at the ATP binding site. *See* **isoflavonoid**.

genome the whole of the genetic information of an organism. It is contained as DNA in eukaryotes and prokaryotes, and as either DNA or RNA in viruses. A given organism has only one genome regardless of whether the organism is haploid, diploid, or polyploid. The term was originally used to denote one haploid set of chromosomes in a eukaryote organism. —**genomic** *adj.*

genome annotation software software that facilitates the creation and maintenance of genome sequence annotation. Examples include Artemis, which allows visualization and annotation especially of the compact genomes of bacteria, archaea, and lower eukaryotes; and Ensembl, which produces and maintains (within a database system) automatic annotation principally for the human genome, but also for the genomes of other vertebrates, with which it provides comparative views.

genome database a database that houses information specific to the genome of a particular organism. For example, ACeDB, Fly-Base, and SGD, house information on the *Caenorhabditis elegans*, *Drosophila melanogaster*, and *Saccharomyces cerevisiae* genomes respectively.

genome mutation any **mutation** (def. 1) occurring by alteration of the number of chromosomes in the genome.

genome project an initiative (often via international collaboration) to map and sequence the entire genome of a particular organism. The first complete prokaryotic and eukaryotic genomes to be sequenced were those of *Haemophilus influenzae* in 1995 and *Saccharomyces cerevisiae* in 1997. The Human Genome Project was completed in 2003, but numerous other genome projects are currently underway. *See* **GOLD**.

genome-regulatory protein any site-specific protein involved in the regulation of transcription, such as a polymerase, repressor, or activator.

genomes online database *abbr.*: GOLD; a Web resource that monitors the status of worldwide genome sequencing efforts, giving access to information about both completed and ongoing projects.

genome survey sequence *abbr.*: GSS; a division of the GenBank database that is genomic in origin (as opposed to cDNA), and includes: single-pass genomic data, exon-trapped sequences, cosmid/BAC/YAC end sequences, and Alu PCR sequences.

genome walking a process in which one end of a genomic DNA clone is used to identify an overlapping clone from a genomic DNA library. Repetition of this procedure several times over results in the assembly of a series of overlapping cloned fragments, or contig.

genomic blotting *an alternative name for* **Southern blotting**.

genomic DNA all of the DNA comprising one genome.

genomic imprinting *see* **imprinting**.

genomic library a set of clones containing DNA fragments that *in toto* embrace an entire genome. It is prepared by firstly randomly cutting the genomic DNA to give fragments of varying length. The average fragment length is controllable by discrimination in the choice of restriction enzymes used for cutting, and is selected to optimize the length such that fragments will contain entire open reading frames without excessive lengths of additional DNA at either end. Secondly the DNA fragments thus obtained are ligated into a suitable **vector** (def. 3), which is cloned in a host of choice.

genomics the systematic sequencing and characterization of com-

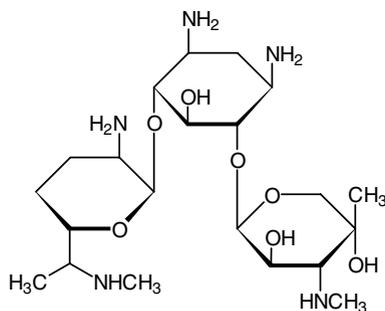

plete genomes. *See also* comparative genomics, functional genomics, +omics, structural genomics.

genophore the structural equivalent of a genetic linkage group in any organism. The term includes the linear chromosome of the (enveloped) eukaryon of all animal and plant cells, the circular chromosome of the (nonenveloped) prokaryon of cells of bacteria, the duplex DNA of mitochondria, chloroplasts, kinetoplasts, plasmids, and episomes, and the nucleic acid, whether DNA or RNA, single-stranded or double-stranded, of viruses.

genotoxin an agent that reacts with and interferes with the action of genetic DNA.

genotype 1 the total genetic constitution of an organism. It comprises the genetic information carried both in the chromosomes and extrachromosomally. *Compare* phenotype. —**genotypic** *adj.*

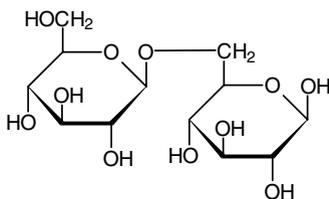

gentamicin or **gentamycin** any of a group of aminoglycoside antibiotics produced by fermentation of some *Micromonospora* spp. They are inhibitors of protein synthesis, and are particularly effective in the treatment of *Pseudomonas aeruginosa* infections.

gentamicin C₁

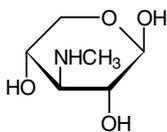

gentianose the trisaccharide, *O*-β-D-glucopyranosyl-(1→6)-*O*-α-D-glucopyranosyl-(1→2)-β-D-fructofuranoside. It is found in the rhizomes of many species of *Gentiana*.

gentiobiose or (formerly) **amygdalose** the disaccharide, *O*-β-D-glucopyranosyl-(1→6)-D-glucose. It is a component of some glycosides, e.g. amygdalin.

β-gentiobiose

gentosamine 3-deoxy-3-methylamino-D-xylose; a component of gentamicin A, one of the structural variants of gentamicin.

genus (*pl. genera*) (*in taxonomy*) a category used in biological classification consisting of species with a common phylogenetic origin that appear to be clearly differentiated from other species.

+**geny** *comb. form* denoting origin or mode of development. —+**genic** *adj.*

geometric isomer or **geometrical isomer** an alternative term for *cis-trans* isomer.

geometric isomerism or **geometrical isomerism** an alternative term for *cis-trans* isomerism.

geometric mean or **geometric average** for *n* positive numbers, the *n*th root of the product of the numbers. Thus for a set of positive numbers $x_1, x_2, x_3, \dots, x_n$, the geometric mean is $(x_1 \cdot x_2 \cdot x_3 \dots x_n)^{1/n}$. *Compare* mean.

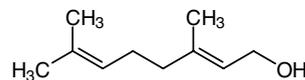

geotaxis the movement of an organism or a cell under the influence of a gravitational field. In **positive geotaxis** the organism moves in the same direction as the gravitational field, while in **negative geotaxis** the movement is in a direction opposite to the gravitational field. —**geotactic** *adj.*

gephryin a cytoplasmic protein that associates with microtubules, and is required for clustering of glycine receptors in spinal cord. It has a role in molybdoenzyme function in non-neuronal tissue.

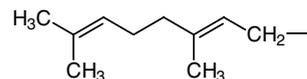

g-equiv *abbr. for* gram-equivalent or gram-equivalent weight.

GERAD *abbr. for* glycoprotein ER-associated degradation; a disposal system for glycoproteins in the endoplasmic reticulum that is signalled by: (1) removal of the outermost mannose residue from the middle branch of an asparagine-linked oligosaccharide core; and (2) misfolding of the associated protein.

geraniol (*2E*)-3,7-dimethyl-2,6-octadien-1-ol, a monoterpene alcohol with a sweet rose odour, present in oil of rose and other essential oils.

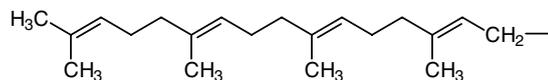

geranyl the (*2E*)-3,7-dimethyl-2,6-octadien-1-yl group. The 1-diphosphate derivative is an intermediate in the synthesis of cholesterol and in the formation of **geranylgeranyl** diphosphate.

geranyl-diphosphate synthase *see* dimethylallyltransferase.

geranylgeranyl the (*2E,6E,10E*)-3,7,11,15-tetramethyl-2,6,10,14-hexadecatetraen-1-yl group. The 1-diphosphate derivative is a substrate for enzymes introducing the geranylgeranyl group into proteins. *See also* prenylation.

geranylgeranyl pyrophosphate synthetase *see* farnesyltransferase.

geranyltransferase EC 2.5.1.10; *systematic name*: geranyl-diphosphate:isopentenyl-diphosphate geranyl transferase; *other names*: farnesyl-diphosphate synthase; farnesyl pyrophosphate synthetase (*abbr.*: FPP synthetase). An enzyme of the pathway synthesizing prenyl groups, sesquiterpenes, and cholesterol. It catalyses the reaction between geranyl diphosphate and isopentenyl diphosphate to form *trans,trans*-farnesyl diphosphate with release of pyrophosphate.

Gerbich system *abbr.*: Ge; a blood-group system whose antigenic determinants are located on the extracellular, glycosylated domain of glycoporphins C and D (GPC and GPD). The polypeptide sequences of these give rise to several Ge phenotypes: on GPD the antigenic site for Ge2 resides between residues 1 and 17, and that for Ge3 resides between residues 19 and 34; on GPC, the antigenic

site for Ge4 is at the N terminus, and that for Ge3 between residues 40 and 55.

GERL *abbr. for golgi, endoplasmic reticulum, lysosomes*; a term formerly used to describe a specialized region of smooth **endoplasmic reticulum** with high levels of acid phosphatase and other acid hydrolase activities. It is thought to be a region where acid hydrolases are concentrated and packaged into lysosomes. It may also be concerned in packaging other materials, including epinephrine granules in the adrenal medulla, tyrosinase and other materials in pre-melanosomes in mouse melanomas, peroxidase, etc. in secretory granules in cells of parotid and submaxillary glands, and un-iodinated thyroglobulin in thyroid epithelial cells.

germ cell any cell of the **germ line**, including **gametes**.

germ-free describing any group of animals or plants that is bred and maintained in such conditions that they contain no microorganisms, either normal symbionts or abnormal, infective ones. *Compare gnotobiotic.*

germin a pepsin-resistant water-soluble glycoprotein of the walls of germinated plant embryos that may alter the properties of cell walls during germinative growth. Its synthesis coincides with the onset of growth in germination. The protein has oxalate oxidase activity.

germ line any line of cells that gives rise to gametes and is continuous through the generations.

Gerstmann–Straussler syndrome a transmissible **spongiform encephalopathy** of humans, usually familial, characterized by widespread degeneration of the nervous system. *See also prion.* [After Joseph Gerstmann (1887–1969), Austrian neurologist.]

GF-1 *see GATA-1.*

g-factor or *g-value*, a parameter in EPR spectroscopy, which defines the field B_0 and frequency ν position of resonance, according to the relation $h\nu = g\mu_B B_0$, where h is the Planck constant and μ_B the Bohr magneton.

GFP *abbr. for green fluorescent protein.*

GFR *abbr. for (renal) glomerular filtration rate.*

Gg₃ *symbol for gangliotriose (alternative to GgOse₃).*

Gg₄ *symbol for gangliotetraose (alternative to GgOse₄).*

GGA a codon in mRNA for a glycine residue.

GGC a codon in mRNA for a glycine residue.

GGG a codon in mRNA for a glycine residue.

GgOse₃ *symbol for gangliotriose (alternative to Gg₃).*

GgOse₄ *symbol for gangliotetraose (alternative to Gg₄).*

GGU a codon in mRNA for a glycine residue.

GH *abbr. for 1 growth hormone (i.e. somatotropin). 2 glycohydrolase.*

ghilanten *see antistatin.*

ghost an empty red-blood-cell membrane, usually obtained by lysis of red cells by the controlled reduction in the osmotic pressure of the suspending medium followed by restoration of normal osmotic conditions causing the membranes to reseal. Ghosts are extensively used in studies of the properties of membranes.

ghrelin a 28-residue acylated polypeptide hormone secreted by endocrine cells of the stomach and duodenum in the human and rat. It strongly stimulates appetite and secretion of somatotropin. Plasma levels rise shortly before and shortly after a meal. It is derived from a precursor protein, proghrelin, from which another appetite-suppressing hormone, **obestatin**, is derived. The two hormones activate distinct receptors. In humans the sequence is

n-octanoylation at serine 3 is essential for activity.

GHRF *abbr. for growth hormone releasing factor (see GHRH).*

GHRH *abbr. for growth hormone releasing hormone; other names: growth hormone releasing factor (abbr.: GHRF) or somatoliberin*; any of a family of peptide hormones that act on the anterior pituitary to stimulate the secretion of growth hormone and exert a trophic effect on the gland. The bovine hormone, for example, consists of 44 amino acids (5.109 kDa), and is derived from a precursor protein. *See also GHRH receptor.*

GHRH receptor *abbr. for growth hormone releasing hormone receptor; other name: growth hormone releasing factor receptor (abbr.: GRFR)*; any of a family of G-protein-associated membrane receptors that bind GHRH and stimulate adenylate cyclase. A de-

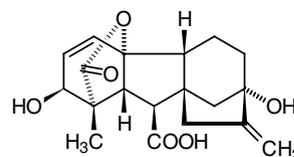

fect in this receptor (Asp⁶⁰ → Gly⁶⁰) is associated with hypoplasia of the anterior pituitary in mice.

GH-RIH *abbr. for growth hormone release inhibiting factor (i.e. somatostatin).*

GHRp *abbr. for growth hormone-releasing peptide.*

giantin an integral membrane protein of the Golgi apparatus that contains a 376 kDa cytoplasmic domain consisting almost exclusively of heptad repeats for coiled-coil formation, and a C-terminal transmembrane segment.

gibberellin any of a widely distributed, multimembered group of highly modified C₂₀ (and C₁₉) terpene plant hormones, the first of which was isolated from plants infected with the fungus *Gibberella fujikuroi*. The most important is gibberellin A₃, also known as **gibberellic acid**. Gibberellins accelerate shoot growth, and can actively stimulate RNA synthesis in dwarf mutant plants, making them grow like normal plants. Other physiological effects, e.g. overcoming the need for vernalization in long-day plants, have also been recorded.

gibberellic acid

Gibbs–Duhem equation an equation relating the chemical potential and concentration of a chemical species in a mixture at constant temperature and pressure. If n_i moles of species i , having chemical potential μ_i , are present in a mixture, then

$$\sum_i n_i d\mu_i = \sum_x x_i d\mu_i = 0$$

where $x_i = n_i/\sum n_i$ is the mole fraction and $d\mu_i$ is the change in chemical potential for dn_i , a small change in the amount of species i present, in moles. [After Josiah Willard Gibbs (1839–1903), US physical chemist, and Pierre Duhem (1861–1916), French physical chemist.]

Gibbs energy or **Gibbs free energy** or **Gibbs function** *symbol: G*; a thermodynamic property of a system; it is defined as $H - TS$, where H is the enthalpy, S the entropy, and T the temperature. For a molecule in solution, Gibbs energy is concentration-dependent. The Gibbs free energy (G_i) of the i th component is equal to the standard free energy of the component (G_i° , the free energy at unit activity) plus a term to adjust for concentration. Thus

$$G_i = G_i^\circ + RT \ln a_i$$

where R is the gas constant, and a_i the activity of the i th component. The molar free energy is referred to as the **chemical potential**.

See also Gibbs free energy change.

Gibbs energy diagram or **Gibbs energy profile** for a chemical reaction, a diagram showing the relative standard Gibbs energies of reactants, transition states, reaction intermediates, and products in the same sequence as they occur in the reaction.

Gibbs energy of activation or **Gibbs free energy of activation** *symbol: $\Delta^\ddagger G^\circ$* ; the standard Gibbs energy difference between the transition state of a chemical reaction (either elementary or stepwise) and reactants.

Gibbs free energy change the difference in Gibbs free energy (G) at any instant in time between the reactants and products of any reaction. Thus for a reaction $A + B \rightleftharpoons C + D$, at any particular concentration of reactants and products, the free energy change, ΔG , for that state is calculated as

$$G_C + G_D - G_A - G_B.$$

Since, for each substance,

$$G_X = G_X^\circ + RT \ln a_X$$

(*see Gibbs energy*), this leads to

$$\Delta G = \Delta G^\circ + RT \ln a\{c_A a_B / (a_A a_B)\};$$

$$\Delta G^\circ = \Delta G^\circ_C + \Delta G^\circ_D - \Delta G^\circ_A - \Delta G^\circ_B,$$

and is the **standard free energy change**. All chemical reactions proceed in the direction of negative free energy change until equilibrium is reached, at which point ΔG is zero. Since at equilibrium $a_C a_D / (a_A a_B)$ is the equilibrium constant K , it follows that the standard free energy change $\Delta G^\circ = -RT \ln K^\circ$ where K° is the standard equilibrium constant.

Gibbs–Helmholtz equation an equation that may be expressed as

$$\Delta G - \Delta H = T[\delta\Delta G/\delta T]_P$$

where ΔG is the change in Gibbs energy during a reaction, ΔH the increase in enthalpy, P the pressure, and T the temperature.

Giemsa's stain a stain used for staining chromosomes, in which it reveals bands known as **G-bands** (from the name). These are rich in A–T nucleotide pairs. Other compounds, e.g. the antibiotic olivomycin, stain G–C-rich bands known as **R-bands** (because they give the 'reverse' of the G-bands). [After Gustav Giemsa (1867–1948), German parasitologist.]

GIF *abbr.* for growth hormone-inhibitory factor (i.e. **somatostatin**).

giga+ *symbol:* G; **1** the SI prefix denoting 10^9 times. **2** (*in computing*) prefix used to indicate a multiple of 2^{30} , e.g. gigabyte.

GIGANTEA a gene of *Arabidopsis thaliana* that is controlled by the circadian clock mechanism and regulates flowering. Its product is predicted to contain several transmembrane segments. It is a key link between clock genes and flowering genes.

gigantism a condition arising from the excessive release of **somatotropin** leading to an individual of excessive size. *Compare* **acromegaly**.

Gilbert syndrome a very mild form of jaundice in which there is increased bilirubin in plasma, predominantly in unconjugated form. Usually diagnosed in young adults, it is transmitted as an autosomal recessive trait. It is caused by an abnormality in the TATA box within the promoter region at 2q37 for UDPglucuronosyltransferase I, which results in reduced expression of the gene, and decreased conjugation of bilirubin as a glucuronoside. *See* **UDPglucuronosyltransferase**. [After Nicholas A. Gilbert (1858–1927), French physician.]

Gilson pipette a proprietary name for one of a range of piston-operated pipettes designed to function with disposable polypropylene tips. Individual pipettes are identified by the maximum volume in microlitres they are designed to deliver, for example P2, P20, P200, P1000. Precise volumes within each range can be delivered. [Named after the manufacturer, Gilson Inc.]

Gim complex an alternative name for **prefoldin**.

GIP *abbr.* for **1 gastric inhibitory peptide**. **2** general insertion pore. *See* **TOM**.

GIPL *abbr.* for glycoinositolphospholipid (*see* **GPI anchor**).

GIRK *abbr.* for G-protein gated inward rectifier K^+ .

GKRP *abbr.* for glucokinase regulatory protein.

Gla *symbol* for a residue of the α -amino acid L-4-carboxyglutamic acid.

Glanzmann thrombasthenia *see* **von Willebrand factor**.

glass electrode an electrode made of glass whose potential, when immersed in a solution, is a function of the hydrogen-ion activity, i.e. pH, of the solution. A common form of glass electrode consists of a thin glass bulb inside which is mounted a reference electrode, often a silver/silver chloride electrode, immersed in a solution of constant pH and containing the ion to which the inner reference electrode is reversible. A number of special glasses have been made in an effort to extend the range of pH over which the electrode responds linearly, to reduce errors caused by other ions in solution, to extend its useful temperature range, etc.

glassmilk an aqueous suspension of a proprietary silica matrix used in the purification of DNA.

glaucoma a group of heterogeneous diseases in which vision is impaired through damage to the optic nerve, and usually associated with increased intraocular pressure. It is the leading cause of irreversible blindness in the world. Depending on the mechanism impeding outflow of aqueous humor from the anterior chamber of the eye, glaucoma is classified into open-angle, closed-angle, or congen-

ital forms. An autosomal dominant primary open-angle glaucoma results from mutations in the gene for **myocilin**. Primary congenital glaucoma is autosomal recessive and commonly caused by mutations in the gene for a cytochrome P450 designated CYP1B1.

Glc *symbol* for a residue (or sometimes a molecule) of the aldohexose **glucose**. In the condensed system of symbolism of sugar residues, Glc signifies specifically a glucose residue with the common configuration and ring size, i.e. D-glucopyranose. (*Note:* Glu is the symbol for a glutamic residue.)

GLC or **glc** *abbr.* for gas–liquid chromatography.

GlcA 1 *symbol* for a residue (or sometimes a molecule) of the uronic acid glucuronic acid. **2** former *symbol* for a residue (or sometimes a molecule) of the aldonic acid **gluconic acid** (no symbol now recommended).

GlcF *symbol* for a glucofuranose residue.

GlcN *symbol* for a residue (or sometimes a molecule) of the amino-deoxysugar **glucosamine**.

GlcNAc *symbol* for a residue (or sometimes a molecule) of the *N*-acetylated aminodeoxysugar ***N*-acetylglucosamine**.

GlcP *symbol* for a glucopyranose residue.

GlcU or **GlcUA** former *symbol* for glucuronic acid (GlcA now recommended).

Gleevec a drug approved for treatment of chronic myeloid leukemia. The drug inhibits a tyrosine kinase enzyme p210 produced by the BCR-ABL oncogene as a result of a translocation from chromosome 22 to 9. A single mutation in the p210 BCR-ABL gene is a source of resistance to Gleevec in blast crisis cells, which leads to reactivation of the enzyme.

Gli any of three vertebrate homologues of the *Drosophila* zinc-finger transcription factor **cubitus interruptus**. Mutations in the Gli3 gene (at 7p13) are associated with the multiple-malformation Pallister–Hall syndrome.

GLI *abbr.* for glucagon-like immunoreactant (or glucagon-like immunoreactivity).

glia or **neuroglia** the special connective tissue of the central nervous system constituting some 40% of the total volume of the brain and spinal cord. It has supportive and nutritive functions and is made up of **glial cells** – oligodendrocytes, astrocytes, ependymal cells, and microglial cells.

gliadin or (formerly) **gliadine** any of a group of proline-rich proteins (**prolamins**) found in the seeds of wheat and rye. All gliadins are mixtures of simple proteins of similar composition and properties. They are differentiated from **glutenin**, with which they are associated in gluten, by their solubility in 70% aqueous ethanol. With water, gliadins form a sticky mass, which binds flour into a dough. They constitute the major seed storage proteins in wheat. Gliadins fall into two groups: α/β gliadins (*also* prolamin or gliadin AI–V) are divided into five classes, by similarity; there are more than 100 copies of the gene per haploid genome; γ -gliadins are divided into three classes (BI–III). For both groups, sequence divergence between the respective classes is the result of single base substitutions, and of duplications or deletions within or near direct repeats. [French *gliadine*; from Greek *glia*, glue.]

glial cell-derived neurotrophic factor *abbr.*: GDNF; a homodimeric protein of the transforming growth factor β (TGF β) family that is secreted in the nervous system and other tissues and promotes neuronal survival during development. Both subunits contain 134 residues and three disulfide bonds, and are derived from a 211-residue precursor. GDNF is structurally related to neurturin and persephin, and like these binds a specific GPI-anchored membrane protein that recruits and signals through **RET** and the adaptor protein GRB-10. Numerous inactivating mutations in RET and a few mutations in GDNF are associated with **Hirschsprung disease**.

glial cells *see* **glia**.

glial derived nexin a glycoprotein serine protease inhibitor, similar to **serpin**, that promotes neurite extension. *See also* **nexin**.

glial fibrillary acidic protein *abbr.*: GFAP; a class III intermediate filament and a cell-specific marker that, during the development of the central nervous system, distinguishes astrocytes from other glial cells. It is similar to other intermediate filament proteins.

glibenclamide *see* **glyburide**.

glycentin a peptide originally obtained as a component of porcine

enteroglucagon, and known at first as **porcine gut GLII**. It reacts fully with antisera to the N-terminal moiety of glucagon from pancreas. The known amino-acid sequence includes the entire sequences of **glicentin-related pancreatic peptide** (at residues 1–30) and pancreatic **glucagon** (at residues 33–61), and is identical to the N-terminal moiety of the sequence of proglucagon. It was initially thought to comprise 100 amino-acid residues, hence the name.

glicentin-related pancreatic peptide or **glicentin-related pancreatic polypeptide** *abbr.*: GRPP; originally, any polypeptide material present in extracts of porcine pancreas and in the secretory granules of the pancreatic A cell that reacted with certain antisera to glicentin, but not with any antisera to glucagon. The term is now usually applied to a specific component of such material that is a 30-residue peptide identical in sequence to the N-terminal 30-residue sequence of **proglucagon**, is secreted by the pancreas concomitantly with glucagon, and thus is probably a cleavage product of proglucagon.

GLI-I *see* **glicentin**.

GLIMA38 *abbr. for* glycosylated islet-cell-membrane antigen 38 kDa; a cell surface antigen of B cells of pancreatic islets that, with **glutamate decarboxylase** (GAD65) and insulinoma antigen-2 (IA-2), elicits autoantibodies in the early phase of the autoimmune response in the development of diabetes mellitus type 1.

glio *see* **platelet-derived endothelial cell growth factor**.

GLIP *abbr. for* glucagon-like insulinotropic peptide; a gastrointestinal peptide that potentiates release of insulin. It is released during a meal and after oral glucose administration. It is GLP-1^{7–37}. *See* **glucagon**.

Gln *symbol for* a residue of the α -amino acid L-glutamine (alternative to Q or Z).

global alignment *see* **alignment**.

global similarity similarity that spans the full extent of a pair or set of aligned sequences (i.e. within a **global alignment**).

globin the colourless and basic protein moiety (and biosynthetic precursor) of **hemoglobin** and **myoglobins**. In normal human adult hemoglobin, the globin component comprises two non-identical pairs of polypeptide chains, whereas in myoglobin there is only one polypeptide chain. Pharmaceutical globin is prepared by adding ox hemoglobin to acetone–HCl; this causes the heme groups to separate and remain in solution, while the globin precipitates. It is used in the preparation of globin–insulin, which is absorbed more slowly than soluble insulin, and has a prolonged action.

globo+ *prefix for* an oligosaccharide, signifying the core structure GalNAc(β 1-3)Gal(α 1-4)Gal(β 1-4)Glc (I), present in **globoside** from which the term originated. Also, by derivation it signifies Gal(α 1-4)Gal(β 1-4)Glc, residues 2–4 of I. *Compare* **isoglobo+**.

globoside or **cytolipin K** *symbol*: GbOse₄Cer or Gb₄Cer; globotetraosylceramide; ceramide globotetraoside; the major neutral glycosphingolipid in normal kidney and erythrocytes. The name originated from the discovery of this lipid on red cells, and led to the use of **globo+** as a root signifying this core carbohydrate structure. *Compare* **globotriaosylceramide**. *See also* **globotetraosylceramide**, **P system**.

globotetraose *symbol*: GbOse₄ or Gb₄; the tetrasaccharide GalNAc(β 1-3)Gal(α 1-4)Gal(β 1-4)Glc. *See also* **P system**, **globo+**.

globotetraosylceramide *symbol*: GbOse₄Cer or Gb₄Cer; a glycolipid having the structure

It is the P determinant in the **P system** of blood groups. *See also* **globo+**.

globotriaose *symbol*: GbOse₃ or Gb₃; the trisaccharide Gal(α 1-4)Gal(β 1-4)Glc. *See also* **globo+**.

globotriaosylceramide *symbol*: GbOse₃Cer or Gb₃Cer; a glycolipid **globoside** having the structure Gal(α 1-4)Gal(β 1-4)GlcCer. It is the major neutral glycosphingolipid in leukocytes, platelets, liver, spleen, and most other non-neural tissues. It is the P^k determinant in the **P system** of blood groups. *See also* **globo+**.

globular protein any protein whose polypeptide chain(s) are folded so as to give the whole molecule a rounded shape; the term is often used loosely to mean soluble as distinct from **membrane proteins**.

globulin any simple, globular protein that is insoluble or sparingly

soluble in water, but soluble in dilute salt solutions, and can be precipitated from solution by half-saturating the solution with neutral ammonium sulfate. Globulins may be distinguished by, e.g., electrophoresis into α -, β -, and γ -globulins, or by ultracentrifugation into 7S globulins, 19S globulins, etc. *See also* **gamma globulin**, **immunoglobulin**.

Globus a freely available toolkit (but not limited to APIs) for grid computing.

glomerular filtrate the filtrate, free of cells and major plasma proteins, that passes from the blood through a renal glomerulus into the lumen of a nephron in the kidney.

glomerular filtration rate *abbr.*: GFR; the rate at which the **glomerular filtrate** is produced in the kidney(s). It is a measure of renal efficiency and is usually expressed in terms of the renal clearance of some substance, e.g. inulin, that is freely filterable by the glomerulus and is neither reabsorbed nor excreted by the renal tubules.

glomerulus (*pl.* **glomeruli**) 1 a knot of blood capillaries projecting into the capsular end of a nephron and from which the **glomerular filtrate** is formed. *See also* **Malpighian body**. 2 any compact tuft or tangled mass of processes, nerve fibres, or blood vessels. —**glomerular** *adj.*

glp a **regulon** of *Escherichia coli* encoding proteins required for the utilization of glycerol 3-phosphate and its precursors. Operons for enzymes of these pathways are controlled negatively by *glp* repressor and positively by the cyclic AMP–cyclic AMP receptor protein complex.

Glp *symbol for* a residue of the α -imino acid L-5-oxoproline (often known as pyroglutamic acid or pyrrolidinecarboxylic acid).

GLP *abbr. for* glucagon-like peptide (*see* **glucagon-related polypeptide**).

Glu *symbol for* a residue of the α -amino acid L-glutamic acid (alternative to E). (*Note*: Glc is the symbol for a glucose residue.)

gluco+ a variant (*sometimes, before a vowel*) of **gluco+**.

glucaemia a variant spelling (*esp. UK*) of **glucemia**; *see* **glucemia**.

glucagon a 29-residue polypeptide hormone synthesized in the A cells of pancreatic islets and mammalian (except human) gastric mucosa. Formerly known as hyperglycemic-glycogenolytic factor (*abbr.*: HGF), or hyperglycemic factor. The amino-acid sequence is identical in human and all other mammalian glucagons (except guinea-pig):

It is secreted in response to falling blood glucose levels and raises the glucose concentration in the blood by either (1) stimulation of adenylate cyclase or (2) activation of inositolphospholipid-specific phospholipase C with increase in intracellular Ca²⁺ concentration. It stimulates glycogenolysis and gluconeogenesis in liver, increases lipolysis in adipose tissue, and increases insulin secretion. Three peptides (glucagon itself and glucagon-like peptides 1 and 2 (GLP-1 and -2)) are roughly 50% homologous in sequence. While GLP-1 is the major form in the pancreas, GLP-1^{7–36}-amide predominates in the intestine. This stimulates insulin secretion and inhibits gastric secretion. Exendin^{9–39} is a GLP-1 receptor antagonist. GLP-1 injected into cerebral ventricles inhibits feeding in the starving rat. This effect is blocked by exendin^{9–39}. *See also* **enteroglucagon**, **glicentin**, **glucagon receptor**, **proglucagon**.

glucagon-37 *see* **enteroglucagon**.

glucagon-like immunoreactant *abbr.*: GLI; any member of a group of peptides found in extracts of mammalian gastrointestinal tract that react with N-terminal-specific anti-glucagon antibodies. A particular component of such material may be denoted by means of a suffixed roman numeral, e.g. GLI-I, and the relative molecular mass of the component in question may be indicated by a superscript, e.g. ⁸⁰⁰⁰GLI. The principal molecular species recorded include one of \approx 12 kDa (¹²⁰⁰⁰GLI), a second of \approx 8 kDa (⁸⁰⁰⁰GLI), and a third of \approx 4.5 kDa (⁴⁵⁰⁰GLI), the first two being the predominant forms. All have glucagon-like biological activities; e.g. they bind to glucagon receptors of liver plasma membrane, activate hepatic adenylate cyclase, and cause the release of insulin. *See also* **glicentin**, **proglucagon**.

glucagon-like insulinotropic peptide *see* **GLIP**.

glucagon-like peptide receptor any of the membrane proteins

that bind glucagon-like peptides (*abbr.*: GLPs) and mediate their intracellular effects. A receptor for GLP-1 has been characterized. It is a seven-transmembrane-segment protein that is coupled to a G-protein activating adenylate cyclase.

glucagonoma a **neoplasm** (benign or malignant), originating usually from the A cells of pancreatic islets, that autonomously secretes **glucagon** or **glucagon-like immunoreactant**, frequently with associated diabetes mellitus.

glucagon receptor any G-protein-associated membrane receptor that binds glucagon and activates adenylate cyclase and phospholipase C. A missense mutation in the gene at 17q25 has been found in a small fraction of diabetes mellitus type 2 patients.

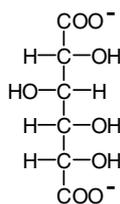

glucagon-related polypeptide or **glucagon-like peptide** any peptide found, e.g. in gastrointestinal tissue and blood, that reacts with anti-glucagon antibodies and contains part or all of the amino-acid sequence of **glucagon**. Such peptides include: **enteroglucagon**, **glucagonin**, **glucagon-like immunoreactant**, and **proglucagon**.

glucan any glycan composed solely of glucose residues. *See also dextran*.

glucan 1,4- α -glucosidase EC 3.2.1.3; *other names*: glucoamylase; amyloglucosidase; α -amylase; lysosomal α -glucosidase; acid maltase; exo-1,4- α -glucosidase. An enzyme that hydrolyses terminal 1,4- α -D-glucosidic bonds (at the nonreducing end) of polysaccharides, producing β -D-glucose with inversion of the configuration. It is less active towards oligosaccharides. Some examples have a raw-starch binding domain. That from *Aspergillus niger* is used commercially in production of glucose. The example from *Neurospora crassa* contains a **kex2** site. Mutations in the human lysosomal enzyme, a glycoprotein of 952 amino acids, cause type II glycogen storage disorder. *See also glucosidase*.

α -glucan phosphorylase a **phosphorylase** with affinity for α -glucans.

glucarate 1 the dianion of glucaric acid, the **aldaric acid** derived from either glucose or gulose. There are two enantiomers L- and D-glucarate; D-glucarate, *formerly known as saccharate*, is derived from either D-glucose or L-gulose (and vice versa for L-glucarate). **2** any salt or ester of glucaric acid.

D-glucarate

glucemia or (*esp. UK*) **glucaemia** an alternative term for **glycemia**.

glucitol *see sorbitol*.

gluco+ or (*sometimes before a vowel*) **gluc+** *comb. form* indicating glucose. *See also glyco+* (def. 2).

gluco- *prefix (in chemical nomenclature)* indicating a particular configuration of a set of (usually) four contiguous CHOH groups as in the acyclic forms of D- or L-glucose. *See monosaccharide*.

glucoamylase another name for **glucan 1,4- α -glucosidase**. *See also glucoamylase complex*.

glucoamylase complex EC 3.2.1.20; an enzyme that splits 1,4- α -D-glucosidic bonds from the nonreducing end of amylose, amylopectin, glycogen, and oligosaccharides including maltose. The human complex is a homodimer (1857 amino acids per subunit), which may also associate with homodimers of sucrase-isomaltase. It shares 59% sequence identity with the latter, and is a type II membrane protein anchored into the small intestinal brush border membrane by an N-terminal transmembrane segment.

β -glucocerebrosidase *see glucosylceramidase*.

glucoconjugate a former term for **glycoconjugate**.

glucocorticoid or **glucocorticosteroid** any natural or synthetic hor-

monal **corticosteroid** that acts primarily on carbohydrate and protein metabolism, e.g. by promoting hepatic glycogen deposition, and that has an anti-inflammatory effect. Glucocorticoids are produced in the middle layer (zona fasciculata) of the adrenal cortex, and include **cortisol**, **corticosterone**, and **cortisone**. In the rat, cortisone is the major product; in humans and most other mammalian species, cortisol is the major product – in humans it is secreted at a rate of ≈ 8 –25 mg per day, compared with corticosterone at 1–4 mg per day. Secretion of glucocorticoids is enhanced during stress, including hypoglycemia, hypotension, trauma (including surgery), and illness. Their main actions include stimulation of liver glucose output (by glycogenolysis and gluconeogenesis), inhibition of glucose utilization by tissues, mobilization of amino acids by breakdown of muscle protein, and mobilization of fatty acids from adipose tissue. Anti-inflammatory actions include stabilization of lysosomal membranes, preventing the release of degradative enzymes, depression of phagocytosis and suppression of T-cell activity, suppressing the synthesis of **interleukin-1**, and stimulating the synthesis of **lipocortin**. Glucocorticoid actions are mediated in large part through **glucocorticoid receptor** molecules, which regulate gene transcription. *Compare mineralocorticoid*.

glucocorticoid receptor a mammalian **transcription factor** involved in the regulation of eukaryotic gene expression and affecting cellular proliferation and differentiation in target tissues. It is a cytosolic, soluble glucocorticoid-binding protein (90 kDa) in a complex with heat-shock protein hsp90 (total mass ≈ 300 kDa). Binding of steroid induces DNA-binding function and translocation to the nucleus where the receptor-steroid complex interacts with DNA at a **glucocorticoid response element** to regulate gene transcription. The receptor contains a modulating N-terminal domain, two DNA-binding zinc fingers in the central region, and a glucocorticoid-binding domain in the C-terminal region. Two isoforms, α (777 residues) and β (742 residues), which differ only in the C-terminal region, are probably generated by alternative splicing of a single gene. The glucocorticoid receptor is similar to other steroid/thyroid/retinoic nuclear hormone receptors.

glucocorticoid response element *abbr.*: GRE; a specific regulatory DNA sequence that mediates the effects of glucocorticoids on gene transcription through interaction with the activated glucocorticoid receptor. It is located upstream of a particular gene. A consensus sequence for one such GRE is the almost palindromic structure GGTACAnnnTGTCT.

glucocortin a protein, M_r 17 000, induced by glucocorticoids in adipocytes, liver, fibroblasts, and thymus, and common to all glucocorticoid target cells examined.

glucogenesis the production of glucose in an organism. This may be from glucose storage forms such as glycogen or starch, from interconversion of other hexoses, or from synthesis from noncarbohydrate precursors.

glucogenic describing a substance, some or all the carbon atoms of which can be used to produce glucose in an organism. A glucogenic amino acid is any amino acid that gives rise to increased urinary glucose excretion when fed to a diabetic animal.

glucokinase 1 *the recommended name* for the enzyme ATP: D-glucose 6-phosphotransferase (EC 2.7.1.2), which catalyses the phosphorylation by ATP of D-glucoseto D-glucose 6-phosphate with release of ADP. The enzyme occurs in invertebrates and microorganisms. Unlike **hexokinase**, which catalyses the same reaction, it is highly specific for D-glucose. **2** a name frequently applied to an isoenzyme of hexokinase (EC 2.7.1.1; hexokinase IV) that is characteristic of mammalian liver and pancreatic B cells. Numerous loss-of-function mutations in the gene for this isozyme result in the commonest form of maturity-onset diabetes of the young (MODY2). A rare activating mutation results in congenital hyperinsulinism.

glucokinase regulatory protein *abbr.*: GKR; a protein that sequesters glucokinase in an inactive state in the cell nucleus.

glucon or (*formerly*) **glucone** any **glycon** in which the sugar involved is glucose.

gluconate 1 the anion of **gluconic acid**. **2** any salt or ester of gluconic acid.

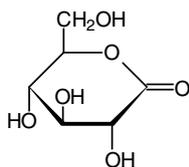

glucooogenesis the metabolic formation of carbohydrates from

non-carbohydrate organic precursors in liver. An important source of precursor molecules is amino acid released from muscle protein during fasting. This is under hormonal control, especially by glucocorticoids. Alanine is an important precursor, and there is extensive conversion in muscle of other amino acids to alanine, which is then transported to the liver, where it undergoes transamination to form pyruvate. *See also gluconeogenic pathway.*

gluconeogenic pathway the pathway in liver by which non-carbohydrate precursors are converted to glucose 6-phosphate and thence to glucose or other carbohydrates. Precursor molecules must first be converted to pyruvate, thence successively to oxaloacetate, phosphoenolpyruvate, 2-phosphoglycerate, 3-phosphoglycerate, 1,3-bisphosphoglycerate, glyceraldehyde 3-phosphate plus glyceraldehyde phosphate, fructose 1,6-bisphosphate, fructose 6-phosphate, glucose 6-phosphate, and glucose (or other sugars). The enzymes involved are in many cases the same as those involved in the corresponding reverse step in the **glycolytic pathway**. The enzymes specific to the gluconeogenic pathway are pyruvate carboxylase, phosphoenolpyruvate carboxykinase, fructose 1,6-bisphosphatase and glucose 6-phosphatase (see individual entries). The pathway is hormonally regulated, especially by glucagon, which increases cyclic AMP levels, thereby stimulating protein kinase activity. Control is effected by phosphorylation of liver pyruvate kinase, which inactivates the enzyme and thus restricts glycolysis, and phosphorylation of phosphofructokinase-2, which converts its action to that of a phosphatase which hydrolyses the 2-phosphate of fructose 2,6-bisphosphate, thereby inactivating phosphofructokinase.

gluconic acid the aldonic acid derived from glucose.

gluconolactone the trivial name for the γ -lactone (D-glucono-1,4-lactone) or δ -lactone (D-glucono-1,5-lactone) of D-gluconic acid.

D-glucono-1,5-lactone

glucophore the common structural feature postulated to be present in molecules of all substances that possess a sweet taste, and thus to confer sweetness on them. The essential components are considered to be a polarized bond A–H (e.g. O–H in a sugar or N–H in a sweet amino acid), an electronegative atom B (typically =O), and a polarizable hydrophobic group X (such as H or Cl). The approximate distances between them are: A–B, 260 pm; A–X, 350 pm; B–X, 550 pm. The groups A–H and B are considered to bind respectively to similar B and A–H groups in the receptor, and the group X to bind to the receptor by charge-transfer or dispersion bonding.

glucoprotein a former name for **glycoprotein**.

glucosaccharase the trivial name for any **saccharase** that attacks the glucose end of appropriate oligosaccharides, liberating glucose.

glucosamine *symbol: GlcpN; the trivial name for the aminodeoxy-sugar 2-amino-2-deoxyglucopyranose; there are two enantiomers. D-Glucosamine (symbol: D-GlcpN), formerly known as chitosamine, occurs in combined form in chitin, in mucoproteins, and in mucopolysaccharides, and is one of the most abundant natural monosaccharides.*

glucosamine N-acetyltransferase EC 2.3.1.3; *other name: glucosamine acetylase; an enzyme forming N-acetyl-D-glucosamine from acetyl-CoA and D-glucosamine while releasing CoA.*

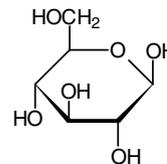

glucosamine-6-phosphate isomerase EC 5.3.1.10; *systematic name: D-glucosamine-6-phosphate ketol-isomerase (deaminating). An enzyme that catalyses the hydrolysis of D-glucosamine 6-phosphate to D-fructose 6-phosphate and NH₃. The amino-acid sequences of bacterial and fungal types are similar.*

glucosaminic acid the common biochemical name for 2-amino-2-deoxygluconic acid.

glucosan 1 an obsolete name for **glucan**. **2** an old trivial name (estab-

lished by usage but not recommended) for 1,6-anhydroglucopyranose.

glucose *symbol: Glc; the trivial name for the aldohexose gluco-hexose; there are two enantiomers, D- and L-glucose. D-(+)-Glucose (symbol: D-Glu), commonly known as glucose, and formerly known as grape sugar or corn sugar, is dextrorotatory, hence also formerly (and sometimes still) known as dextrose; it is 0.74 times as sweet as sucrose. Aged aqueous solutions of D-glucose contain an equilibrium mixture of α -D-glucopyranose, β -D-glucopyranose, and the open-chain form (see also mutarotation), whereas in crystals α -D-glucopyranose monohydrate is the stable form below 50°C. Combined D-glucose may have either the α or the β configuration, but is invariably in the pyranose form. D-Glucose is an important source of energy for living organisms. It is found free in fruits and other parts of plants, in honey, and in animals, especially in the blood (\approx 5 mm in human blood). In combined form it occurs in many homo- and hetero-oligosaccharides and polysaccharides, especially in the animal storage polysaccharide glycogen and in the plant storage polysaccharides cellulose and starch.*

β -D-glucose

glucose-alanine cycle or **alanine cycle** a metabolic cycle in which alanine is formed peripherally, e.g. in muscle, by transamination of glucose-derived pyruvate, and is transported to the liver where its carbon skeleton is reconverted to glucose.

glucose-assimilation coefficient *symbol: K; see glucose-tolerance test.*

glucose-dependent insulinotropic peptide or **glucose-dependent insulin-releasing peptide** *see gastric inhibitory peptide.*

glucose effect the ability of glucose in the growth medium to inhibit the synthesis of certain enzymes in bacteria growing on the medium. *See also catabolite repression.*

glucose fatty-acid cycle a concept to explain how changes in plasma levels of glucose and fatty acids influence one another to provide a homeostatic control mechanism. Its essential features are: (1) the release, for oxidation, of fatty acids from muscle or adipose tissue acylglycerols restricts glucose metabolism in muscle; and (2) glucose uptake by muscle or adipose tissue restricts the release of fatty acids from acylglycerols in these tissues. The cycle thus provides a hormone-independent mechanism tending to maintain a constant plasma glucose level in animals that feed intermittently. Insulin modifies this mechanism by enhancing glucose uptake by muscle and adipose tissue, inhibiting fatty-acid release by adipose tissue, and increasing fatty-acid esterification in both muscle and adipose tissue.

glucose-galactose malabsorption a rare autosomal recessive disorder caused by mutations in the gene for Na⁺-glucose transporter 1. *See glucose transporter.*

glucose isomerase a bacterial enzyme preparation that catalyses the reaction:

It is used on a large scale in industry to convert glucose-containing materials to the much sweeter mixture of glucose plus fructose. The enzymes are usually immobilized on a variety of supports. The product is known as **high-fructose corn syrup** and is widely used as a sweetening agent. No enzyme for which this is the main function has been isolated. EC 5.3.1.18 (glucose isomerase) is now a deleted entry.

glucose oxidase EC 1.1.3.4; *other names: glucose oxyhydrase; notatin; systematic name: β -D-glucose: oxygen 1-oxidoreductase; a flavoprotein (FAD) enzyme that catalyses the oxidation by di-*

oxygen of β -D-glucose to D-glucono-1,5-lactone and H_2O_2 . It has application in the experimental determination of glucose concentration (e.g. in medicine) and has some industrial uses.

glucose-1-phosphatase EC 3.1.3.10; *systematic name*: D-glucose-1-phosphate phosphohydrolase. An enzyme that catalyses the hydrolysis of D-glucose 1-phosphate to D-glucose and orthophosphate.

glucose-6-phosphatase EC 3.1.3.9; *systematic name*: D-glucose-6-phosphate phosphohydrolase. An enzyme that catalyses the hydrolysis of D-glucose 6-phosphate to D-glucose and orthophosphate. It has rather wide specificity. It is the final enzyme in the **gluconeogenic pathway**. The human enzyme is an integral membrane protein (357 amino acids, nine transmembrane segments) of the endoplasmic reticulum (ER), particularly in liver, kidney, and pancreatic B cells. The active site is in the ER lumen. Its activity is increased by starvation and diabetes mellitus, and decreased by insulin. It forms part of a system that includes ER transporters for: glucose-6-phosphate (429 amino acids, 10 transmembrane segments), for glucose, and for phosphate. Deficiency of any of these four components leads to a specific form of type I glycogen storage disease.

glucose-6-phosphate dehydrogenase *abbr.*: G6PDH or (*in clinical chemistry*) GPD; EC 1.1.1.49; *recommended name*: glucose-6-phosphate 1-dehydrogenase; *systematic name*: D-glucose-6-phosphate:NADP⁺ 1-oxidoreductase; *other name (obsolete)*: Zwischenferment. An enzyme that catalyses the conversion of D-glucose 6-phosphate and NADP⁺ to D-glucono-1,5-lactone 6-phosphate and NADPH. This is an early step in the **pentose phosphate pathway** and the **Entner–Doudoroff pathway**, and thus in **heterolactic fermentation**. The enzyme has the greatest known variability of all enzymes in humans. Over 130 molecular variants that result in deficient activity are associated with a drug-induced hemolytic anemia, **favism**. This arises because the enzyme is involved in maintaining reduced glutathione in red cells. *See also* **glucose-6-phosphate dehydrogenase deficiency**.

glucose-6-phosphate dehydrogenase deficiency an X-linked deficiency of **glucose-6-phosphate dehydrogenase** that affects mostly males. It is associated with a hemolytic anemia, but also confers some protection against malaria, since the parasite is unable successfully to pass through the schizont stage in red cells lacking this enzyme activity; hence there is a particularly high incidence in tropical Africa and the Middle and Far East. Lack of the enzyme in red cells results in failure to reduce NADP⁺ to NADPH in adequate amounts (the **pentose phosphate pathway** playing a major role in this in the red cell), as a result of which oxidized glutathione cannot be reduced by **glutathione reductase**. Consequently, there can be hemolysis, as hemoglobin is not maintained in the ferrous state and the peroxides produced as a result of drug action promote red-cell destruction. The antimalarial drug **primaquine** and related compounds generate oxidative stress. Over 130 mutations result in some degree of deficiency. *See also* **favism**.

glucose-6-phosphate isomerase *abbr.* (*in clinical chemistry*): GPI; EC 5.3.1.9; *systematic name*: D-glucose-6-phosphate ketol-isomerase; *other names*: phosphoglucose isomerase; phosphohexose isomerase; phosphohexomutase; oxoisomerase; hexosephosphate isomerase; phosphosaccharomutase; phosphoglucoisomerase; phosphohexoisomerase. A homodimeric cytosolic enzyme of the glycolytic pathway that catalyses the interconversion of glucose 6-phosphate and fructose 6-phosphate. Loss-of-function mutations in the enzyme (558 amino acids) result in an autosomal recessive chronic hemolytic anemia that may be associated with mental retardation and myopathy. Monomeric GPI is identical with neureulekin.

glucose-tolerance curve the curve relating blood glucose concentration to time that is obtained in a **glucose-tolerance test**, either oral or intravenous.

glucose-tolerance factor *abbr.*: GTF; *also called*: chromodulin. A water-soluble, relatively stable organic chromium complex of $M_r \approx 500$ that is believed to be required in the diet for normal glucose tolerance in animals, including humans. It is a coordination complex between chromium (III) ions, nicotinate, glycine, glutamate, and cysteine or glutathione.

glucose-tolerance test any procedure designed to assess the re-

sponse of an individual to a loading dose of glucose, widely used in the diagnosis of diabetes mellitus. The standard **oral glucose tolerance test** is performed in the morning after 12 hours of fasting following at least 3 days' unrestricted diet, physical activity, and freedom from medication. After collection of the fasting blood sample, 75 g (or 1.75 g per kg of body weight for children) glucose is ingested in 5 minutes in 200–500 mL water. Blood samples are then collected at 30-minute intervals for 2 hours, and urine samples are collected at 0, 1, and 2 hours. All samples are assayed for glucose. For capillary blood samples, a maximum glucose level below 10 mmol L⁻¹ (180 mg/100 mL) and a 2-hour value less than 7.5 mmol L⁻¹ (135 mg/100 mL) are the criteria for normality. If venous blood is used the corresponding values are 8.9 mmol L⁻¹ (160 mg/100 mL) and 6.1 mmol L⁻¹ (110 mg/100 mL). The urine samples should be glucose free. The **intravenous glucose tolerance test** may be used when abnormal carbohydrate absorption from the gut is suspected. A common procedure is to take a fasting blood sample and further samples at 10-minute intervals for 1 hour following intravenous injection of 50 mL of 50% w/v glucose solution over a period of 2 minutes. Glucose is assayed in the blood samples and the logarithms of the values are plotted against time. The slope of the resulting straight line, multiplied by 100, is the **glucose-assimilation coefficient**, *K*, which represents the percentage fall in blood glucose per minute. Values of *K* in excess of 1.1 per cent per minute are taken as normal.

glucose transporter any sugar-transport protein for which glucose is a substrate. Apart from certain ABC types (e.g., in *Escherichia coli*), many glucose transporters belong to the 12-helix superfamily of integral transmembrane proteins. They resemble one another and also the typically sugar-H⁺ symport proteins of bacteria, even though the mammalian examples are usually facilitated-diffusion proteins. The human type 4 (insulin responsive, muscle and brown fat) glucose transporter is a candidate for the factor responsible for certain post-receptor defects in non-insulin-dependent diabetes mellitus. *See also* **sugar transporter**.

glucosylase any **glycosidase** that hydrolyses *O*-glucosyl-, *N*-glucosyl-, or *S*-glucosyl-compounds.

α -glucosidase EC 3.2.1.20; *systematic name*: α -D-glucoside glucohydrolase; *other names*: maltase; glucoinvertase; glucosidosucrase; maltase-glucoamylase. An enzyme that hydrolyses maltose and terminal (nonreducing end) 1,4- α -D-glucosidic bonds of oligosaccharides to yield α -D-glucose with retention of configuration. Maltases from some sources (especially intestine) act also on polysaccharides and may slowly hydrolyse (1 \rightarrow 6)- α -D-glucosidic linkages as well. Most active with oligosaccharides, the enzyme catalyses the final step in the degradation of starch and is widely distributed in plants. *See also* **glucan 1,4- α -glucosidase**.

β -glucosidase EC 3.2.1.21; *systematic name*: β -D-glucoside glucohydrolase; *other names*: cellobiase; gentiobiase. An enzyme that hydrolyses terminal (nonreducing end) 1,4- β -D-glucosidic bonds to yield β -D-glucose with retention of configuration.

glucoside or (*formerly*) **glycoside** any **glycoside** (def. 1) in which the sugar moiety is a glucose residue.

glucosinolate a class of sulfur-containing glycosides produced by brassica plants and relatives as part of their defence against pathogens. Glucosinolates are grouped according to the nature of their side chains, which are derived from aliphatic, indolyl, or aralkyl α -amino acids. Tissue damage causes compartmentation with release of the thioglycosidase myrosinase. This releases D-glucose and an unstable aglycone from the glucosinolates. The aglycone then forms toxic isothiocyanate, thiocyanate, or nitrile derivatives.

glucosuria the presence of glucose in the urine. It is sometimes loosely referred to by the older term **glycosuria**, which now strictly implies the presence of any type of sugar in urine. Glucosuria occurs in **diabetes mellitus** and is diagnostically important. It may also occur because of renal defects, as in **Fanconi syndrome**. *See also* **fructosuria**.

glucosyl any glycosyl group formed by detaching the anomeric hydroxyl group, on C-1, from a cyclic form (pyranose or furanose) of glucose or a glucose derivative.

glucosylated hemoglobin a *mismomer* for **glycated hemoglobin**.

glucosylation **glucosylation** with one or more glucosyl groups. — **glucosylated** *adj.*

glucosylceramidase EC 3.2.1.45; *other names:* β -glucocerebrosidase; acid β -glucosidase; *systematic name:* D-glucosyl-N-acylsphingosine glucohydrolase; a lysosomal glycoprotein enzyme that catalyses the hydrolysis of D-glucosyl-N-acylsphingosine to D-glucose and N-acylsphingosine. The enzyme requires saposin C for activity. A deficiency of this enzyme is the cause of **Gaucher's disease**, in which there is an accumulation of glucocerebroside. *See* **saposin**.

glucosylceramide *the recommended term for any D-glucosyl-N-acylsphingosine, i.e. any cerebroside in which the sugar moiety is D-glucose.*

glucosyloxy any of the glucosyloxy groups formed by detaching the hydrogen atom from the anomeric hydroxyl group, on C-1, from a cyclic form (pyranose or furanose) of glucose.

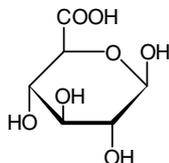

glucosyltransferase any hexosyltransferase enzyme (EC 2.4.1) for which the glucosyl group transferred is glucosyl. The acceptor may be orthophosphate (as for e.g. **phosphorylase**), but more often is another carbohydrate molecule (as for e.g. **glycogen synthase**) and sometimes a lipid (as in the synthesis of 3-D-glucosyl-1,2-diacylglycerol). *See* **D enzyme**. *See also* **B-transferase**, **lactose synthase**, **Lewis transferase**.

glucuronate 1 the anion of glucuronic acid. **2** any salt or ester of glucuronic acid.

glucuronate pathway or **glucuronate oxidation pathway** the metabolic pathway by which D-glucuronate is converted, via L-gulonate, L-xylulose, xylitol, and D-xylulose, to D-xylulose 5-phosphate, an intermediate in the pentose phosphate pathway. In **essential pentosuria** there is defective conversion of L-xylulose to xylitol. In a side branch of the pathway L-ascorbate is formed, via L-gulonolactone, from L-gluconate. Primates and the guinea pig lack the ability to convert L-gulonolactone to L-ascorbate (*see* **ascorbic acid**).

glucuronate reductase EC 1.1.1.19; *systematic name:* L-gulonate:NADP⁺ 6-oxidoreductase. An enzyme that reduces the aldehyde group at C-1 of D-glucuronate thus forming L-gulonate. *See* **glucuronate pathway**.

glucuronic acid *abbr. (sometimes):* GA; *symbol:* GlcA (or (formerly) GlcU or GlcUA); the uronic acid formally derived from glucose by oxidation of the hydroxymethylene group at C-6 to a carboxyl group. There are two enantiomers; D-glucuronic acid is widely distributed in plants and animals, where it usually occurs as glucuronides.

β -D-glucuronic acid

β -glucuronidase *abbr. (in clinical chemistry):* GRS; EC 3.2.1.31, an enzyme that catalyses the hydrolysis of a β -D-glucuronoside to D-glucuronate and the corresponding hydroxy compound, which may be an alcohol, a phenol, or a saccharide. Deficiency of β -glucuronidase occurs in human type VII mucopolysaccharidosis. It is a homotetramer, and a lysosomal enzyme.

glucuronide *former name for glucuronoside.*

glucuronoside or (formerly) **glucuronide** any compound formed by combination in (α or β) glycosidic linkage of a hydroxy compound with the anomeric carbon atom of glucuronate. The hydroxy compound may be a saccharide, an alcohol, or a phenol. β -D-Glucuronosides are formed in so-called **detoxication** reactions.

glucuronosyl the glucosyl group formed by removal of the anomeric hydroxyl group from glucuronic acid or glucuronate.

glucuronosyltransferase *another name for UDPglucuronosyltransferase.*

glucuronoyl the univalent acyl group derived from glucuronic acid. **glued** *see* **dynactin**.

Glu(NH₂) (formerly) *symbol for a residue of the α -amino acid L-glutamine (Gln or Q now recommended).*

Glu-NH₂ *symbol for a residue of the α -amino acid L-isoglutamine.*

Glu(OEt) *symbol for a residue of γ -ethyl glutamate; O⁵-ethyl hydrogen glutamate.*

Glu-OEt *symbol for a residue of α -ethyl glutamate; O¹-ethyl hydrogen glutamate.*

GluR receptor *see* **glutamate receptor**.

GLUT *an abbr. commonly used for glucose transporter.*

glutaconyl-CoA decarboxylase EC 4.1.1.70; an enzyme that catalyses the decarboxylation of glutaconyl-CoA (pent-2-enoyl-CoA) to but-2-enoyl-CoA, releasing CO₂. Biotin is a coenzyme. The enzyme is dependent on Na⁺, and functions as a sodium pump in the bacterial membrane.

glutamate 1 (*in biochemistry*) glutamate(1-); glutamic-acid monoanion; hydrogen glutamate. In theory, the term denotes any ion, or mixture of ions, formed from **glutamic acid**, and having a net charge of -1, although the species $\text{OOC-}[\text{CH}_2]_2\text{-CH(NH}_3^+\text{)-COO}$ generally predominates in practice. **2** (*in chemistry*) *the systematic name for glutamate(2-); glutamic-acid dianion.* **3** any salt containing an anion of glutamic acid. **4** any ester of glutamic acid.

glutamate N-acetyltransferase EC 2.3.1.35; *other names:* ornithine acetyltransferase; ornithine transacetylase; an enzyme of the pathway in bacteria for the formation of ornithine from glutamate. It catalyses a reaction between N²-acetyl-L-ornithine and L-glutamate to form L-ornithine and N-acetyl-L-glutamate (*abbr.:* AGA). AGA is then converted to N-acetylglutamate 5-semialdehyde, which undergoes transamination to N²-acetylornithine. In *Bacillus stearothermophilus* it is a bifunctional enzyme (*other name:* AGS/OCTase) containing activities for this and also **amino-acid N-acetyl transferase**.

glutamate-ammonia ligase EC 6.3.1.2; *systematic name:* L-glutamate:ammonia ligase (ADP-forming); *other name:* glutamine synthetase. An enzyme that catalyses a reaction between ATP, L-glutamate, and NH₃ to form ADP, orthophosphate, and L-glutamine. This is the first step in the fixation of ammonia in plants, the ATP-dependent incorporation of NH₄⁺ into the amide position of glutamine. The second step involves L-glutamate synthase (ferredoxin) and the combined effect of the two enzymes is to produce L-glutamate from 2-oxoglutarate and ammonium (NH₄⁺), a major NH₄⁺ assimilatory route. Glutamate-ammonia ligase has a molecular mass of 33 kDa and its eight monomers are arranged in two stacked tetramers. The protein from *Escherichia coli* consists of 12 subunits in two hexagons. The activity is controlled by adenylation of a tyrosine residue in the presence of ATP by [**glutamate-ammonia-ligase**] **adenylyl transferase**. The fully adenylylated dodecamer is inactive; transcription is regulated by **nitrogen regulatory protein**.

[**glutamate-ammonia-ligase**] **adenylyltransferase** EC 2.7.7.42; *other name:* glutamine-synthetase adenylyltransferase; an enzyme that catalyses the adenylation of [L-glutamate:ammonia ligase (ADP-forming)] by ATP to form adenylyl-[L-glutamate:ammonia ligase (ADP-forming)] with release of pyrophosphate. The adenylation regulates enzyme activity (*see* **glutamate-ammonia ligase**).

glutamate/aspartate transporter any membrane protein that transports glutamate and aspartate. Two types are known. (1) A H⁺-symport protein of the bacterial (inner) membrane; it is probably a 12-helix integral membrane protein. Although Na⁺ is not involved, there is a sequence resemblance to the second type (below). (2) The sodium-dependent transporter of brain; it is similar to sodium-dicarboxylate symporters. Putatively, it is a glycosylated integral membrane protein of brain (high levels in Purkinje cell layer).

glutamate dehydrogenase (NADP⁺) EC 1.4.1.4; *systematic name:* L-glutamate:NADP⁺ oxidoreductase (deaminating). An enzyme that catalyses the oxidation by NADP⁺ of L-glutamate to form 2-oxoglutarate, NH₃, and NADPH. Two forms exist: one is a homotetramer; the other form, found in bacteria and plants, mainly proceeds in the direction of glutamate synthesis, as an NH₃-assimilatory enzyme; it is the product of the *am* gene, and is a homohexamer. Isoforms of this enzyme provided the first demonstration of **interallelic complementation**.

glutamate–cysteine ligase EC 6.3.2.2; *other name*: γ -glutamylcysteine synthetase; the first cytosolic enzyme for the formation of glutathione. It catalyses the formation of γ -L-glutamyl-L-cysteine from ATP, L-glutamate, and L-cysteine with release of ADP and orthophosphate. The mammalian enzyme is a heterodimer. Deficiency in humans produces glutathione deficiency associated primarily with chronic hemolysis.

glutamate decarboxylase *abbr.*: GAD; EC 4.1.1.15; a decarboxylase enzyme necessary for the production of γ -amino-*n*-butyric acid (GABA) from glutamate, with pyridoxal phosphate as coenzyme. GAD65 (585 amino acids; gene at 10p11) is present in small vesicles in brain and in pancreatic islets. Autoantibodies to it occur early in the development of diabetes mellitus type 1, being present in the plasma in $\approx 90\%$ of such patients. They are also present in $\approx 60\%$ of patients with stiff-man syndrome. GAD65 shows sequence homology over 22 residues with a sequence in Coxsackie virus P2-C protein. The gene for GAD67 at 2q31 encodes 594 amino acids.

glutamate dehydrogenase EC 1.4.1.2; *systematic name*: L-glutamate:NAD⁺ oxidoreductase (deaminating). An enzyme that catalyses the reaction:

This oxidative removal of the amino group from glutamate avoids the need for an oxo-acid acceptor, and in **ureotelic** animals is a major route for the removal of nitrogen as NH₄⁺, which is then converted to urea in the **ornithine–urea cycle**. *See also* **glutamate dehydrogenase (NADP⁺)**.

glutamate dehydrogenase (NADP⁺) EC 1.4.1.4; *systematic name*: L-glutamate:NADP⁺ oxidoreductase (deaminating). An enzyme that catalyses the oxidation by NADP⁺ of L-glutamate to form 2-oxoglutarate, NH₃, and NADPH. Two forms exist. One is a homotetramer. The other form, found in bacteria and plants, mainly proceeds in the direction of glutamate synthesis, as an NH₃-assimilatory enzyme. It is the product of the *am* gene, and is a homohexamer. Isoforms of this enzyme provided the first demonstration of **interallelic complementation**.

glutamate–oxaloacetate transaminase *see* **aminotransferase**.

glutamate–pyruvate transaminase *see* **aminotransferase**.

glutamate receptor *abbr.*: GluR; any membrane protein that binds glutamate and mediates its effects in neurotransmission. Over 20 genes encode human GluRs, which may be ionotropic and act as ligand-gated ion channels or metabotropic G-protein-associated membrane proteins. Some GluR gene products are subject to RNA editing. **Ionotropic GluR receptors** are subdivided into three classes, named after their agonists: (1) *N*-methyl-D-aspartate (NMDA) receptors, which play a key role in memory acquisition, learning, and neurological disorders and are the target for **conantokin-G**; (2) α -amino-3-hydroxy-5-methyl-4-isoxalone (**AMPA**) receptors, formerly designated quisqualate receptors; and (3) kainate receptors. Most of the fast excitatory synaptic transmission in the vertebrate central nervous system is mediated by GluR channels. Generally they have a broad ionic selectivity to monovalent ions; NMDA channels are also five to ten times more permeable to Ca²⁺ ions than to Na⁺ or K⁺ ions. Subunits (designated α , β , γ , δ , ϵ , and ζ) of these channels contain four putative transmembrane segments. The members of the α subfamily constitute AMPA-selective GluR channels; the β and γ subfamilies include the subunits of the kainate-selective GluR channel; NMDA receptor channels are composed of $\epsilon\zeta$ heteromers. **Metabotropic GluR receptors** (mGluR) include mGluR₁, of which two alternatively spliced versions exist (1199 and 906 amino acids), and mGluR₂ (872 amino acids); both activate phospholipase C.

glutamate 1-semialdehyde glutamic α -semialdehyde; the L enantiomer, L-glutamate 1-semialdehyde, (S)-4-amino-5-oxopentanoate, is the precursor of 5-aminolevulinate (*see* **glutamate-1-semialdehyde 2,1-aminomutase**). It is synthesized in plants from glutamate bound to a specific tRNA; after reduction of the 1-carboxyl group, the tRNA is removed to yield glutamate 1-semialdehyde. *Compare* **glutamate 5-semialdehyde**.

glutamate 5-semialdehyde glutamic γ -semialdehyde; the L enantiomer, L-glutamate 5-semialdehyde, (S)-2-amino-5-oxopentanoate, is an intermediate in the synthesis of proline from orn-

ithine. In plants and bacteria it is formed in a pathway in which L-glutamate is first converted to *N*-acetyl-L-glutamate, which is reduced to *N*-acetyl-L-glutamate 1-semialdehyde, from which the acetyl group is then removed. In animals it is formed from ornithine by transamination of the δ -amino group. *See* **proline**. *Compare* **glutamate 1-semialdehyde**.

glutamate-1-semialdehyde 2,1-aminomutase EC 5.4.3.8; *other name*: glutamate-1-semialdehyde aminotransferase. The enzyme synthesizing 5-aminolevulinate in plants; it catalyses the conversion of (S)-4-amino-5-oxopentanoate (i.e. **glutamate 1-semialdehyde**) to 5-aminolevulinate.

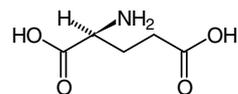

glutamate synthase (ferredoxin) EC 1.4.7.1; *systematic name*: L-glutamate:ferredoxin oxidoreductase (transaminating). An enzyme that catalyses the second step in the fixation of ammonia in plants, i.e. the transfer of the NH₂ group from the amide group of glutamine to 2-oxoglutarate to form L-glutamate. The reaction is between L-glutamine, 2-oxoglutarate, and two molecules of reduced ferredoxin; the products are two molecules of L-glutamate and two of oxidized ferredoxin. In plants the combination of the action of **glutamate–ammonia ligase** and this enzyme results in the production of one molecule of glutamate from one of 2-oxoglutarate and one of NH₄⁺. *See also* **glutamate synthase (NADH)**, **glutamate synthase (NADPH)**.

glutamate synthase (NADH) EC 1.4.1.14; *systematic name*: L-glutamate:NAD⁺ oxidoreductase (transaminating). An enzyme that catalyses a reaction between L-glutamine, 2-oxoglutarate, and NADH to form two molecules of L-glutamate and NAD⁺. FMN is a cofactor.

glutamate synthase (NADPH) EC 1.4.1.13; *systematic name*: L-glutamate:NADP⁺ oxidoreductase (transaminating). An enzyme that catalyses the formation of two molecules of L-glutamate and one of NADP⁺ from L-glutamine, 2-oxoglutarate, and NADPH. It is an iron–sulfur flavoprotein. It brings together nitrogen and carbohydrate metabolism in bacteria, since in association with **glutamate–ammonia ligase** it functions as the second step in a major NH₃-assimilatory pathway. It exists as an aggregate of four heterodimers of large and small subunits; glutamine binds to the large subunit and transfers –NH₂ from its amido group to 2-oxoglutarate, which apparently binds to the small subunit.

glutamic *the general name for a residue of glutamic acid, whether or not the γ -carboxyl group is protonated.*

glutamic acid *abbr.* (sometimes): GA; *the trivial name for α -aminoglutaric acid; 2-aminopentanedioic acid; HOOC–[CH₂]₂–CH(NH₂)–COOH; a chiral α -amino acid. L-Glutamic acid (symbol: E or Glu), (S)-2-aminopentanedioic acid, is a coded α -amino acid found in peptide linkage in proteins; codon: GAA or GAG (anticodon: CUU). In mammals, it is a non-essential dietary amino acid, and is glucogenic. Residues of D-glutamic acid (symbol: D-Glu or D-Glu), (R)-2-aminopentanedioic acid, are found in the cell-wall material of various bacterial species, and (as poly-D-glutamic acid) in the capsular substances of *Bacillus anthracis*, *B. subtilis*, and other bacteria. One residue of D-glutamic acid per molecule occurs in the antibiotic bacitracin A (*see* **bacitracin**) and also in **glutathione**.*

L-glutamic acid

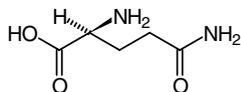

glutamic amide 1 glutamic 1-amide (i.e. **isoglutamine**). **2** glutamic 5-amide (i.e. **glutamine**).

glutaminase EC 3.5.1.2; *other and systematic name*: L-glutamine amidohydrolase; an enzyme that catalyses the hydrolysis of L-glutamine to L-glutamate and NH₃.

glutamate 1 the glutamine anion; the anion, H₂N–CO–[CH₂]₂–CH(NH₂)–COO[–], derived from glutamine. **2** any salt containing glutamate anion. **3** any ester of glutamine.

glutamine *the trivial name for the γ -amide of glutamic acid; glu-*

tamic 5-amide; α -aminoglutaric acid; 2-amino-4-carbamoylbutanoic acid; $\text{H}_2\text{N}-\text{CO}-[\text{CH}_2]_2-\text{CH}(\text{NH}_2)-\text{COOH}$; a chiral α -amino acid. L-Glutamine (*symbol*: Q or Gln or *formerly*) Glu(NH_2); (S)-2-amino-4-carbamoylbutanoic acid, is a coded α -amino acid found in peptide linkage in proteins; codon: CAA or CAG (anticodon: GUU). In mammals, it is a non-essential α -amino acid, and is glucogenic. D-Glutamine (*symbol*: D-Gln or D-Gln), (R)-2-amino-4-carbamoylbutanoic acid, is not known to occur naturally. *Compare isoglutamine*.

L-glutamine

glutamine amidotransferase *abbr.*: GATase; a *nonsystematic name* for carbon–nitrogen ligases that employ glutamine as the amido-N-donor; i.e. members of the sub-subclass EC 6.3.5. These enzymes transfer the $-\text{NH}_2$ group from glutamine to another reactant, e.g. **GMP synthase**. The enzyme activity is also an activity associated with **CAD protein** in mammals. *See also glutamate synthase (ferredoxin), glutamate synthase (NADH), glutamate synthase (NADPH)*.

glutamine–pyruvate aminotransferase EC 2.6.1.15; *other names*: glutaminase II; glutamine–oxo-acid transaminase; glutamine transaminase L; an enzyme that catalyses the reaction:

Pyridoxal-phosphate is a cofactor. *See also transamination*.

glutamine repeat a protein sequence consisting exclusively of glutamyl residues. Expansion of the length of the repeat in several proteins, for example ataxins, androgen receptor, and huntingtin, is associated with various forms of spinocerebellar ataxia, spinobulbar muscular atrophy, and Huntington's disease, respectively. The length expansion leads to protein misfolding and aggregation, formation of cellular inclusion bodies, and neurotoxicity.

glutamine synthetase *see* glutamate–ammonia ligase.

glutamine-synthetase adenyllyltransferase *see* [glutamate–ammonia-ligase] adenyllyltransferase.

glutamine transaminase L *see* glutamine–pyruvate aminotransferase.

glutamino 1 *N*²-glutamino the alkylamino group, $\text{H}_2\text{N}-\text{CO}-[\text{CH}_2]_2-\text{CH}(\text{COOH})-\text{NH}-$, derived from glutamine by loss of a hydrogen atom from its α -amino group. **2** *N*⁵-glutamino the acylamino group, $\text{H}_2\text{N}-\text{CH}(\text{COOH})-[\text{CH}_2]_2-\text{CO}-\text{NH}-$, derived from glutamine by loss of a hydrogen atom from its amide group.

glutaminyl the acyl group, $\text{H}_2\text{N}-\text{CO}-[\text{CH}_2]_2-\text{CH}(\text{NH}_2)-\text{CO}-$, derived from glutamine. *Compare isoglutaminyl*.

glutamo the alkylamino group, $\text{HOOC}-[\text{CH}_2]_2-\text{CH}(\text{COOH})-\text{NH}-$, derived from glutamic acid.

glutamoyl the diacyl group, $-\text{CO}-[\text{CH}_2]_2-\text{CH}(\text{NH}_2)-\text{CO}-$, derived from glutamic acid.

α -glutamyl glutam-1-yl; the α -monoacyl group, $\text{HOOC}-[\text{CH}_2]_2-\text{CH}(\text{NH}_2)-\text{CO}-$, derived from glutamic acid.

γ -glutamyl or *formerly*) isoglutamyl, glutam-5-yl; the γ -monoacyl group, $-\text{CO}-[\text{CH}_2]_2-\text{CH}(\text{NH}_2)-\text{COOH}$, derived from glutamic acid.

glutamyl aminopeptidase EC 3.4.11.7; *other names*: aminopeptidase A; angiotensinase A; differentiation antigen gp160; an enzyme that removes an N-terminal glutamyl residue from a peptide. It can also hydrolyse N-terminal aspartase, and can thus inactivate **angiotensin II**, being expressed in kidney, as well as on cells of the capillaries and intestine, and on lymphocytes.

γ -glutamyl cycle a cycle of chemical events that uses the γ -carboxyl group of glutamate to transport amino acids actively across (mammalian) cell membranes. Glutathione reacts by transpeptidation with the amino acid to be transported. The resulting γ -glutamylamino acid enters the cell, where it is split into the free amino acid and 5-oxoproline. The latter is then converted to glutamate in an ATP-dependent reaction. The cysteinylglycine is hydrolysed by a

peptidase. Glutathione is then regenerated in two ATP-dependent steps. *See also glutamyltransferase*.

glutamyl endopeptidase γ -glutamylcysteine synthetase *see* glutamate–cysteine ligase.

glutamyl endopeptidase EC 3.4.21.19; *other names*: staphylococcal serine proteinase; V8 proteinase; protease V8; endoproteinase Glu-C. An enzyme that catalyses the preferential cleavage: Asp-|-Xaa, Glu-|-Xaa.

glutamyltransferase *abbr.* (in clinical chemistry): GMT; EC 2.3.2.2; *recommended name*: γ -glutamyltransferase; *systematic name*: (5-L-glutamyl)-peptide:amino acid 5-glutamyltransferase; *other name*: γ -glutamyl transpeptidase. An ectoenzyme of plasma membrane that reversibly transfers a γ -L-glutamyl residue (linked to the substrate by an isopeptide bond) from the N terminus of a peptide, normally glutathione, to the amino group of an amino acid. It is present in high concentrations in liver, kidney, prostate, and pancreas, and is useful diagnostically in liver or biliary disease, and cirrhosis, and also in pancreatitis; it is also elevated in the plasma of alcoholics. The level in normal human (male) plasma is $<60 \text{ IU L}^{-1}$. *See also γ -glutamyl cycle*.

glutaraldehyde pentanedial; a compound that is useful as a tissue fixative in electron microscopy, as a crosslinking agent for compounds containing amino groups, and as a sporicide.

glutaramic acid the *trivial name* for 4-carbamoylbutanoic acid; $\text{H}_2\text{N}-\text{CO}-[\text{CH}_2]_3-\text{COOH}$; the monoamide of glutaric acid (*see glutarate*).

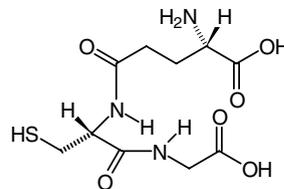

glutarate 1 *trivial name* for propane-1,3-dicarboxylate; pentanedioate; $-\text{OOC}-[\text{CH}_2]_3-\text{COO}-$; the dianion of glutaric acid (pentanedioic acid). **2** any mixture of free glutaric acid and its mono- and dianions. **3** any (partial or full) salt or ester of glutaric acid.

glutaredoxin a monomeric polypeptide with a similar function to thioredoxin. It can replace thioredoxin, or may be the main reactant, in the pathway for nucleotide reduction.

glutaric acidemia or (*esp. Brit.*) **glutaric acidemia** the abnormal elevation of levels of glutaric and hydroxyglutaric acids in plasma and their excessive excretion in urine. **Type I** glutaric acidemia is associated with severe infantile dyskinesia and dystonia, and results from numerous mutations that produce deficiency of **glutaryl-CoA dehydrogenase**. **Type II** is associated with metabolic acidosis and hypoglycemia, and results from mutations in **electron-transfer flavoprotein** or **electron-transferring flavoprotein dehydrogenase**.

glutaryl-CoA dehydrogenase EC 1.3.99.7; a flavoprotein decarboxylase that catalyses the reaction between glutaryl-CoA and electron transfer flavoprotein (ETF) to form crotonoyl-CoA, CO_2 , and reduced ETF. *See glutaric acidemia*.

glutathione *abbr.*: GSH; *symbol*: Glu-(Cys-Gly); γ -glutamylcysteinylglycine, a tripeptide that is widely distributed in most if not all cells. It acts as a coenzyme for some enzymes and as an antioxidant in the protection of sulfhydryl groups in enzymes and other proteins; it has a specific role in the reduction of hydrogen peroxide and oxidized ascorbate, and it participates in the γ -glutamyl cycle. Oxidation links two molecules by a disulfide bond (represented as GSSG). For clarity, glutathione is sometimes termed **reduced glutathione** (or the reduced form of glutathione). It is involved in the synthesis of certain leukotrienes.

glutathione dehydrogenase (ascorbate) EC 1.8.5.1; an enzyme that catalyses the reduction by two molecules of glutathione of dehydroascorbate to form oxidized glutathione and ascorbate.

glutathione peroxidase EC 1.11.1.9; *systematic name*: glu-

tathione:hydrogen-peroxide oxidoreductase. An enzyme that catalyses the reaction:

It has a UGA-encoded selenocysteine residue at its active site. Its main role is to protect hemoglobin from oxidative breakdown: the oxidized glutathione is reduced by **glutathione reductase**, the system thus contributing to a reduction of peroxide levels in the cell.

glutathione reductase *abbr.* (in clinical chemistry): GTD; EC 1.6.4.2; *recommended name:* glutathione reductase (NADPH); *systematic name:* NADPH:oxidized-glutathione oxidoreductase. A homodimeric enzyme that catalyses the reaction:

It has FAD as cofactor, and is important in maintaining glutathione in the reduced state.

glutathione synthase EC 6.3.2.3; *other name:* glutathione synthetase; the second cytosolic enzyme of the formation of glutathione from ATP, γ -L-glutamyl-L-cysteine, and glycine with release of ADP and orthophosphate. The mammalian enzyme is a homodimer. Deficiency in humans produces glutathione deficiency, (5)-oxoprolinuria, hemolysis, and central nervous system symptoms.

glutathione transferase EC 2.5.1.18; *systematic name:* RX:glutathione R-transferase; *other names:* glutathione S-alkyltransferase; glutathione S-aryltransferase; S-(hydroxyalkyl)glutathione lyase; glutathione S-alkyltransferase; glutathione S-transferase. Glutathione transferases catalyse various glutathione-dependent reactions:

(1) nucleophilic substitution, e.g.

where RX is an aryl- or alkyl-halide (EC 2.5.1.18); (2) addition of GSH across activated unsaturated carbon-carbon or carbon-nitrogen bonds (often α,β -unsaturated ketones/ thiones) or oxirane, e.g.

(3) organic hydroperoxide reduction (selenium-independent GSH peroxidase):

(4) organic nitrite reduction

(5) isomerizations in which GSH acts as cofactor, e.g. conversion of prostaglandin H to prostaglandin D. The proteins also bind a variety of hydrophobic anions, e.g. hematin, fatty acid and steroid metabolites, and various xenobiotics/metabolites including the GSH conjugates which may be their catalytic products. Such binding is responsible for their retention by S-linked GSH-Sepharose, hence the widely used simple purification of **GST fusion proteins**. GSH transferases were originally identified as binding proteins (*see ligandin*) and are widely distributed, abundant dimeric soluble enzymes or trimeric membrane-bound forms. They are generally considered an important part of phase II metabolism of xenobiotics. Five classes of soluble GSH transferase subunits have been distinguished (α , μ , π , θ , and σ) and heterodimers occur at least within classes yielding, for example, about 20 different isoenzymes in the rat. Distinct soluble mitochondrial and bacterial forms also occur.

glutelin any member of a group of simple proteins found especially in the seeds of cereal plants. They are insoluble in water, dilute salt solutions, and ethanol, but are soluble in dilute acids or alkalis. The group includes the **glutenins** of wheat, the hordenins of barley, and the oryzemins of rice. They serve as storage proteins, and have Gln-rich domains. *Compare prolamins*.

gluten a proteinaceous fraction obtained from certain cereal seeds, especially wheat, consisting of a considerable number of proteins that are all either **glutenins** or **prolamins**. It forms a sticky mass when wet, and gives dough its characteristic consistency. *See also celiac disease*.

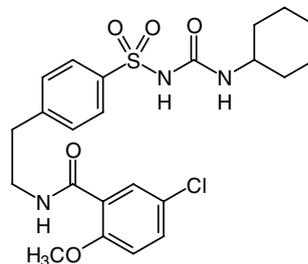

glutenin any **glutelin** of the endosperm of wheat seeds. Glutenins form aggregates of high molecular mass in which they are linked to-

gether by disulfide bridges; they are thought to be responsible for the viscoelastic properties of wheat dough. The sequences contain a central low-complexity region, rich in glutamine, proline, glycine, tyrosine, threonine, and serine residues; these cluster within several different types of repeating unit, but all sequences include QQPQGQ and QQQYYPTS motifs. *Compare gliadin*.

Glx *general symbol* for a residue of any α -amino (or imino) acid that yields L-glutamic acid on acid hydrolysis. It was formerly used only for L-glutamic acid (*specific symbol:* Glu) or L-glutamine (*specific symbol:* Gln), but is now used to represent any such residues, including those of L-4-carboxyglutamic acid (*specific symbol:* Gla) and 5-oxoproline (= pyroglutamic acid) (*specific symbol:* Glp); (alternative to Z).

Gly *symbol* for a residue of the achiral (α -)amino acid glycine (alternative to G).

glyburide 1-[[p-[2-(chloro-*o*-anisamido)ethyl]phenyl]sulfonyl]-3-cyclohexylurea; glibenclamide; a sulfonylurea with oral hypoglycemic actions similar to **tolbutamide**.

glyc+ a variant form of **glyco+** (before a vowel).

glycaemia a variant spelling (*esp. UK*) of **glycemia**.

glycamine any ω -amino- ω -deoxyalditol, i.e. any compound formally derived from an **alditol** by replacement of a terminal hydroxyl group by an amino group.

glycan or **polysaccharide** any polymer consisting of more than about 10 monosaccharide (i.e. glucose) residues joined by glycosidic linkages. A **homoglycan** (or **homopolysaccharide**) contains only one type of monosaccharide residue, whereas a **heteroglycan** (or **heteropolysaccharide**) contains two or more different kinds of monosaccharide residue. A homoglycan is named, generally, after the constituent monosaccharide, with the +ose ending replaced by +an; hence, cellulose, dextran, dextrin, and starch are all glucans, since they consist of glucose. *Compare glycosan*.

glycaric acid an obsolescent name for **aldaric acid**.

glycated hemoglobin or **glycohemoglobin** any derivative of hemoglobin that is formed nonenzymically by reaction at the N terminus with glucose. In the normal adult human such derivatives constitute a few percent of the total erythrocyte hemoglobin, the most abundant being **hemoglobin A_{1c}**, which increases severalfold in concentration in diabetes mellitus, and is assayed to monitor control of diabetes. Glycation of other proteins such as lens crystallins, collagen and low-density lipoproteins has been implicated in the pathogenesis of diabetic complications. It is sometimes improperly termed **glycosylated hemoglobin** or **glycosylated hemoglobin**. *See also glycation*.

glycated proteins glycation is the post-translational modification of a protein by the covalent attachment of a sugar residue, resulting from the spontaneous amino-carbonyl reaction (the **Maillard reaction**) between these two moieties. The reaction occurs principally between the free amino groups of proteins and the carbonyl group of reducing sugars, as first described by Louis-Camille Maillard in 1912. The initial condensation to form a Schiff's base is a spontaneous, but reversible, reaction that is rapidly followed by a complex series of irreversible reactions, ultimately leading to generation of Amadori products of brown pigments, and cross-linking of the polypeptide chains involved. The importance of the Maillard reaction has long been recognized in the food industry, where it causes spoilage, and produces colour and off-flavour in cooked foods. In 1977, Cerami identified an Amadori product in variants of human

glycerol-3-phosphate cytidylyltransferase

In the cytosol NAD-linked **glycerol-3-phosphate dehydrogenase (NAD⁺)** catalyses the reduction of glycerone phosphate (formed together with glyceraldehyde 3-phosphate in glycolysis) to *sn*-glycerol 3-phosphate. The latter enters the mitochondria where it is oxidized to glycerone phosphate by the FAD-linked mitochondrial glycerol-3-phosphate dehydrogenase. The glycerone phosphate then returns to the cytosol to complete the cycle. The overall result is the oxidation of cytosolic NADH + H⁺ to NAD⁺ and the reduction of mitochondrial enzyme-FAD to enzyme-FADH₂.

glycerol-3-phosphate cytidylyltransferase EC 2.7.7.39; *other name*: CDPglycerol pyrophosphorylase; an enzyme that catalyses the formation of CDPglycerol from CTP and *sn*-glycerol 3-phosphate with release of pyrophosphate.

glycerol-3-phosphate dehydrogenase *abbr.*: G3PDH; EC 1.1.99.5; a flavoprotein enzyme that catalyses the oxidation by an electron acceptor of *sn*-glycerol 3-phosphate to glycerone phosphate. It is part of the **glycerol 3-phosphate cycle**. In *Escherichia coli* there are two unrelated enzymes: anaerobic G3PDH, which is an iron-sulfur flavoprotein comprising two subunits; and aerobic G3PDH.

glycerol-3-phosphate dehydrogenase (NAD⁺) EC 1.1.1.8; *systematic name*: *sn*-glycerol-3-phosphate:NAD⁺ 2-oxidoreductase. An enzyme that catalyses the reaction:

Its role is especially important in the provision of glycerol 3-phosphate for lipid synthesis, using glycerone phosphate derived from glucose by the **glycolytic** pathway, and as a component of the **glycerol-3-phosphate cycle**. See **flightin**.

glycerol-3-phosphate O-acyltransferase EC 2.3.1.15; *systematic name*: acyl-CoA:*sn*-glycerol-3-phosphate 1-O-acyltransferase; it catalyses the acylation by acyl-CoA of glycerol 3-phosphate to form 1-acyl-*sn*-glycerol 3-phosphate (lysophosphatidic acid) with release of CoA. This is the first step in phospholipid biosynthesis and may be involved in regulation of membrane biogenesis. Plants exhibit oleate-selective acyltransferases; the enzyme from chilling-resistant plants discriminates against palmitic acid (a fatty acid with high transition temperature), and selects oleic acid (leading to more fluid membranes), whereas the acyltransferase from sensitive plants accepts both fatty acids.

glycerol-3-phosphate oxidase EC 1.1.3.21; *systematic name*: *sn*-glycerol-3-phosphate:oxygen 2-oxidoreductase. An enzyme that catalyses the oxidation by dioxygen of *sn*-glycerol 3-phosphate to glycerone phosphate and hydrogen peroxide; FAD is a cofactor. It is a mitochondrial protein. In insects it plays an important role in the transfer of energy for flight, along with **glycerol-3-phosphate dehydrogenase (NAD⁺)** (flightin).

glycerol trinitrate see **trinitroglycerine**.

glycerone *symbol*: Grn; *the currently recommended trivial name* for dihydroxyacetone; 1,3-dihydroxy-2-propanone. It is the simplest ketose, is achiral, and is a constitutional isomer of glyceraldehyde.

glycerone phosphate *the currently recommended trivial name* for dihydroxyacetone phosphate; 1,3-dihydroxy-2-propanone 1-phosphate; the monoester formed by phosphorylation of dihydroxyacetone, glycerone. Glycerone phosphate and D-glyceraldehyde 3-phosphate are together described as triose phosphates and are interconvertible by triose-phosphate isomerase, EC 5.3.1.1. They are important components of the glycolytic pathway. Glycerone phosphate is a precursor of the glycerol moiety of glycerolipids.

glycerone transferase see **transaldolase**.

glycerophosphate *an alternative name for glycerol phosphate*.

α -glycerophosphate cycle *an alternative name for glycerol-3-phosphate cycle*.

glycerophosphate phosphatidyltransferase EC 2.7.8.5; *recommended name*: CDPdiacylglycerol-glycerol-3-phosphate 3-phosphatidyltransferase. An enzyme that catalyses a reaction between CDPdiacylglycerol and *sn*-glycerol-3-phosphate to form 3-(3-*sn*-phosphatidyl)-*sn*-glycerol 1-phosphate, with release of CMP. It is a membrane protein of endoplasmic reticulum and component of the pathway for the biosynthesis of acidic phospholipids; its product

glycine hydroxymethyltransferase

loses phosphate to form phosphatidylglycerol from which **cardiolipin** is formed.

glycerophospholipid *general name* for any derivative of glycerophosphate that contains at least one *O*-acyl, *O*-alkyl, or *O*-alkenyl group attached to the glycerol residue. Formerly known as phosphoglyceride.

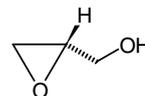

glycerophosphoric acid see **glycerol phosphate**.

glycerose *alternative name* (not recommended) for **glyceraldehyde**.

glyceroyl 2,3-dihydroxypropanoyl; the acyl group, HOCH₂-CH(OH)-CO-, derived from glyceric acid.

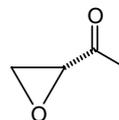

glyceryl any group derived from glycerol by replacing or removing one or more of its hydroxyl groups.

glycidol *the trivial name for* 3-hydroxypropylene oxide; 2,3-epoxy-1-propanol.

S(-)-glycidol

glycidoyl 2,3-epoxypropanoyl; the acyl group derived from glycidic acid.

(R)-glycidoyl group

glycidyl 2,3-epoxypropyl; the alkyl group: derived from glycidol by removal of its hydroxyl group.

glycinamide *the trivial name for* the amide of glycine, aminoacetamide; aminoethanamide; H₂N-CH₂-CO-NH₂. It is predominantly cationic at neutrality and is useful as a buffer substance; pK_a (20°C) = 8.20.

glycinamide ribonucleotide synthetase (*abbr.* GARS) see phosphoribosylamine-glycine ligase.

glycinamide ribotide *N*-glycyl-5-phosphoribosylamine; an early intermediate in the biosynthesis of purines.

glycinate **1** glycine anion; the anion, NH₂-CH₂-COO⁻, derived from **glycine**. **2** any salt containing glycine anion. **3** any ester of glycine.

glycine *symbol*: G or Gly; *the trivial name for* aminoacetic acid; aminoethanoic acid; H₂N-CH₂-COOH; an achiral (α)-amino acid, and the simplest naturally occurring amino acid. It is a coded amino acid found in peptide linkage in proteins; codon: GGA, GGC, GGG, or GGU (anticodon: CCU). In mammals, it is a non-essential dietary amino acid, and is **glucogenic**. It is sweet-tasting, hence its name. [From **glyc(o)** (def. 1) + **-ine** (def. 1)]

glycine amidinotransferase EC 2.1.4.1; an enzyme that catalyses the formation of guanidinoacetate, a precursor of **creatine**, from L-arginine and glycine, also forming L-ornithine.

glycine betaine *N*-trimethylglycine. See **betaine**.

glycine cleavage enzyme or **glycine oxidase** (when working in the reverse direction); a multienzyme complex that resembles the pyruvate dehydrogenase complex but contains the following elements: **P protein**, a pyridoxal phosphate-dependent glycine decarboxylase; **H protein**, a lipamide-containing aminomethyltransferase; **T protein**, an N⁵,N¹⁰-methylene tetrahydrofolate synthesizing enzyme; and **L protein**, an NAD-dependent, FAD-requiring lipamide dehydrogenase. It provides the major mechanism for glycine degradation in mammalian tissues.

glycine hydroxymethyltransferase EC 2.1.2.1; *systematic name*: 5,10-methylenetetrahydrofolate:glycine hydroxymethyltransferase;

other names: serine hydroxymethylase; threonine aldolase; serine aldolase. An enzyme that catalyses the reaction:

It is a pyridoxal phosphate-requiring enzyme that interconverts glycine and serine; it transfers a hydroxymethyl group from N^5, N^{10} -methylene tetrahydrofolate to a glycine-pyridoxal phosphate Schiff base or from a serine-pyridoxal phosphate Schiff base to tetrahydrofolate.

glycine receptor a complex of integral membrane proteins that binds glycine and mediates its effects as an inhibitory neurotransmitter in lower brain areas and spinal cord. It is a pentamer of α (four isoforms, $\alpha 1$ – $\alpha 4$) and β subunits, and forms an intrinsic Cl^- channel, blocked by strychnine (distinguishing it from the GABA_A Cl^- channel). All subunits have four transmembrane segments, M1–M4, M3 and M4 being separated by a cytoplasmic hydrophilic loop; this is comparable to nicotinic acetylcholine receptors (*see cholinergic receptor*) and GABA_A receptors (*see GABA receptor*), with which some sequence similarities also exist. Glycine also binds to a site on the NMDA (glutamate) receptor, which must be occupied by glycine to enable activation of the receptor by NMDA, and is also blocked by strychnine.

glycine-rich proteins *abbr.:* GRP; one of the four major groups of **plant cell-wall proteins**. Glycine-rich proteins can contain over 70% glycine residues, are predicted to form beta sheets, and are thought to form a platelike structure at the interface between the plasma membrane and cell wall, perhaps becoming crosslinked to the latter. They are not heavily glycosylated.

glycinin a 350 kDa **globulin** that is the chief protein constituent of the soya bean, *Glycine max*. Structurally, it resembles **arachin**, **edestin**, and **excelsin**.

glycinium glycine cation; the cation, $\text{H}_3\text{N}^+ - \text{CH}_2 - \text{COOH}$, derived from **glycine**.

glycino the alkylamino group, $\text{HOOC} - \text{CH}_2 - \text{NH}-$, derived from **glycine**.

glycitol an *obsolescent name for alditol*.

glyco+ or (*before a vowel*) **glyc+ comb. form 1** indicating sweet-tasting. **2 a** indicating sugar. **b** (*in medicine*) indicating glucose. *See also gluco+*. **3** (*in chemical nomenclature*) indicating covalently linked to carbohydrate. **4** indicating combination with glycine; e.g. **glycocholate**, **glycocyanine**.

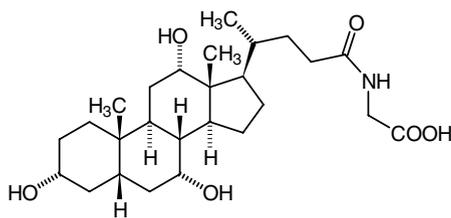

glycoamino acid any compound in which a saccharide is combined with an amino acid through any kind of covalent linkage. The term includes **glycosylamino acids**.

glycobiology the branch of biochemistry dealing with **glycoconjugates**, including their structure, analysis, function, and metabolism.

glycocalicin a carbohydrate-rich hydrophilic fragment, M_r 130 000, cleaved from the external portion of the α chain of **glycoprotein Ib** by protease action.

glycocalyx or **cell coat** a zone surrounding many plant and animal cells that is rich in glycoproteins and proteoglycans.

glycocholate 1 the anion of glycocholic acid; *N*-cholyglycine; a bile acid. The anions of similar glycine conjugates of other bile acids are known, e.g. glycochenodeoxycholate, **glycodeoxycholate**, glycolithocholate. **2** any salt of glycocholic acid. Sodium glycocholate is the chief **bile salt** in humans and herbivorous animals. It is useful as a detergent; aggregation number 2.1, CMC 7.1 mm.

glycocholic acid

glycocoll an *obsolete name for glycine*.

glycoconjugate or (*formerly*) **glucoconjugate** any large and complex biological molecule that contains a carbohydrate moiety. The term comprehends glycolipid, glycopeptide, glycoprotein, peptide glycan, proteoglycan, and heteroglycan. *See also glyco+* (def. 3), **conjugate** (def. 5).

glycoconjugate syndrome an *alternative name for carbohydrate-deficient glycoprotein syndrome*.

glycocyanine an *older name for N-amidinoglycine*; guanidinoacetic acid. In polychaete worms, the guanidine group can undergo phosphorylation to phosphoglycocyanine, which acts as a **phosphagen**.

glycodeoxycholate 1 glycodeoxycholic acid; *N*-deoxycholyglycine; a bile acid. **2** any salt of glycodeoxycholic acid; sodium glycodeoxycholate is useful as a detergent; aggregation number 2, CMC 2.1 mm.

glycoform any of several differently glycosylated variants of a specified glycoprotein. Glycoforms may vary in the type, number and/or position of the sugar residues, differ in their physiological properties (e.g., rate of action), and occur together in a given tissue.

glycogen a polydisperse, highly branched glucan or polyglucose, composed of chains of D-glucose residues in $\alpha(1\rightarrow4)$ glycosidic linkage, joined together by $\alpha(1\rightarrow6)$ glycosidic linkages; a small number of $\alpha(1\rightarrow3)$ glycosidic linkages and some cumulative $\alpha(1\rightarrow6)$ links also may occur. Its structure is similar to that of **amylopectin** but with more, though rather shorter, branches; those in glycogen variously contain 8 to 12 glucose residues. The size of the molecule varies greatly according to source and method of measurement, with average M_r values of 2.5×10^5 to upwards of 1.5×10^7 reported. Glycogen serves as a cellular store of glucose; it occurs, frequently as granules, in all animal tissues, especially liver and skeletal muscle, and also in some bacteria and yeasts. The glycogen molecule is linked to the protein **glycogenin** which is required for the *ab initio* synthesis of glycogen by **glycogen synthase**.

glycogenase an *alternative name for either α - or β -amylase*.

glycogen branching enzyme *see branching enzyme*.

glycogen disease or **glycogen storage disease** or **glycogenosis** any human disease in which there is an inherited abnormality in glycogen metabolism. Such diseases have been classified into eight types. Type I glycogen disease (*or von Gierke's disease*) involves a deficiency of hepatic **glucose-6-phosphatase** or of the endoplasmic reticulum (ER) transporter for glucose-6-phosphate, for glucose, or for phosphate. It is an autosomal recessive disease of infants, characterized by massive hepatomegaly, failure to thrive, severe hypoglycemia, and increased hepatic content of normal glycogen. Type II glycogen disease (*or Pompe's disease*) involves a generalized deficiency of lysosomal α -**glucosidase**. It is an autosomal recessive disease of infants, characterized by massive cardiomegaly, hypotonia, and an increased content of normal glycogen in virtually all tissues. Type III glycogen disease (*or limit dextrinosis or Cori's disease*) involves a generalized deficiency of amylo-1,6-glucosidase (debrancher enzyme) (EC 3.2.1.33). It is an autosomal recessive disease of infants that is similar to, but milder than, type I glycogen disease. It is characterized by an elevated content of glycogen in muscle, liver, and erythrocytes, the glycogen having abnormally short outer branches. A number of subtypes have been recognized. Type IV glycogen disease (*or amylopectinosis or Andersen's disease*) is a rare condition of infants in which there is a generalized deficiency of 1,4- α -glucan branching enzyme (EC 2.4.1.18). It is characterized by hepatic cirrhosis, hepatosplenomegaly, ascites, and glycogen with abnormally long outer branches; the glycogen may not accumulate excessively. Type V glycogen disease (*or McArdle's disease*) involves a deficiency of glycogen phosphorylase (EC 2.4.1.1) in voluntary muscle. The disease is probably autosomal recessive. It is characterized by myoglobinuria and painful cramps occurring during strenuous exercise, symptoms that do not usually appear until 20 years of age. There is no hypoglycemia but muscular exercise fails to elevate the blood lactate concentration. Type VI glycogen disease (*or Hers's disease*) involves an increased hepatic glycogen content and a lowered hepatic glycogen phosphorylase (EC 2.4.1.1) activity but a normal phosphorylase-activating system. The clinical course is mild. Type VII glycogen disease involves a deficiency of

muscle **6-phosphofructokinase**. The disease is probably autosomal recessive and is clinically identical to Type V glycogen disease. There are raised contents in muscles of normal glycogen, glucose 6-phosphate, and fructose 6-phosphate, together with a lower than normal concentration of fructose 1,6-bisphosphate. Type VIII glycogen disease involves a reduced **phosphorylase kinase** activity in the liver and in leukocytes. Thought to be inherited as an X-linked character, the disease is characterized by mild hepatomegaly, increased liver glycogen content, and mild hypoglycemia. Type IX glycogen disease results from phosphorylase kinase deficiency. There are several forms depending on which subunit (or isoform) is affected. At least five other types exist, but are very rare.

glycogenesis the metabolic formation of glycogen from sugar (i.e. glucose).

glycogenetic of or relating to the production of glycogen. (*Note:* The term is often used confusingly in the senses of **glycogenic** (def. 1, 2).)

glycogenic 1 of, relating to, or involving glycogen. **2** of or relating to the formation of sugar (i.e. glucose), especially in animals; **glucogenic**. (*Note:* the term is often used confusingly in the sense of **glycogenetic**.)

glycogenin EC 2.4.1.186; *recommended name:* glycogenin glucosyltransferase; a protein that is required for the initiation of glycogen synthesis by glycogen synthase. Glycogenin catalyses formation of a glycosidic link between a glucose and one of its own tyrosines (Tyr¹⁹⁴ in human), and then catalyses addition of a further five glucose molecules. UDPglucose is the donor of the glucose units. This forms a primer, which is then extended with further glucose molecules by **glycogen synthase**. Glycogen synthase is only catalytically efficient when it is bound to glycogenin. This has two consequences: first, the number of glycogen granules is determined by the number of molecules of glycogenin, and second, elongation stops when the synthase is sterically prevented from contact with glycogenin, which forms the core of the particle. Hence, the glycogenin–synthase interaction limits the size of glycogen granules. Glycogenin is a monomeric glycoprotein (via its reactivity), tightly bound to the 86 kDa catalytic subunit of glycogen synthase.

glycogenolysis the breakdown of glycogen into glucose, either by hydrolysis or via glucose 1-phosphate and glucose 6-phosphate. The term is sometimes restricted to the phosphorolysis of glycogen to glucose 1-phosphate. —*glycogenolytic adj.*

glycogenesis *an alternative name for glycogen disease.*

glycogen phosphorylase *see phosphorylase.*

glycogen phosphorylase kinase EC 2.7.11.1; *recommended name:* ATP:phosphorylase-*b* phosphotransferase, other names glycogen phosphorylase kinase; PHK; phosphorylase *b* kinase. An enzyme that phosphorylates a specific serine residue in each of the subunits of the dimeric phosphorylase *b*. Requires Ca²⁺ and calmodulin for activity.

glycogen storage disease *an alternative term for glycogen disease.*

glycogen synthase EC 2.4.1.11; *recommended name* (example): glycogen (starch) synthase (the nature of the synthetic product should be included in the name); *systematic name:* UDPglucose:glycogen 4- α -D-glucosyltransferase; *other name:* UDPglucose–glycogen glucosyltransferase. An enzyme that catalyses the reaction between UDPglucose and (1,4- α -D-glucosyl)_n to form (1,4- α -D-glucosyl)_{n+1} with release of UDP. The mammalian enzyme requires glucosylated **glycogenin** as a primer (product of glycogenin glucosyltransferase, EC 2.4.1.186), and is susceptible to allosteric activation by glucose 6-phosphate, and phosphorylation by a cyclic AMP-dependent kinase. *See also dependent form of glycogen synthase, glycogenin, starch synthase.*

[glycogen-synthase-D] phosphatase EC 3.1.3.42; an enzyme that hydrolyses phosphate from glycogen synthase D, thereby activating it.

glycogen synthase kinase-3 *abbr.* GSK-3; a cytosolic serine/threonine protein kinase that (like several other protein kinases) phosphorylates one or more of nine serine residues in each subunit of **glycogen synthase**. It may be regulated by inactivation by protein kinase B in response to insulin. It is an important component of **Wnt** protein signalling during embryonal patterning and development and also thereafter. Wnt signalling inactivates GSK-3 by targeting

it (in a complex with APC protein, β -catenin, and axin) for ubiquitination and proteosomal degradation. Human GSK-3 (420 amino acids) is highly homologous to SHAGGY (514 amino acids) of *Drosophila*. *Arabidopsis thaliana* contains ten GSK-3/SHAGGY-like kinase genes.

glycogen synthase α kinase *see non-specific serine/threonine protein kinase.*

glycoglycerolipid any **glycolipid** containing one or more glycerol residues.

glycohemoglobin or (*esp. UK*) **glycohaemoglobin** *an alternative term for glycated hemoglobin.*

glycoinositolphospholipid *see GPI anchor.*

glycol 1 ethylene glycol; ethane-1,2-diol; HOCH₂–CH₂OH. **2** or **glychol** any dihydric alcohol, i.e. any compound in which two alcoholic hydroxyl groups are on different carbon atoms (which are usually but not necessarily adjacent).

glycolaldehyde hydroxyacetaldehyde; hydroxyethanal; HOCH₂–CHO.

glycolate or (*formerly*) **glycollate 1** *the trivial name for* hydroxyacetate; hydroxyethanoate; the anion, HOCH₂–COO[–], derived from **glycolic acid**. It is an important metabolite in C₃ plants. **2** any mixture of glycolic acid and its anion. **3** any salt or ester of glycolic acid. It is formed from phosphoglycolate, a product of **ribulose biphosphate carboxylase** when this is acting as an oxidase. It is converted to glyoxylate by glycolate oxidase (*see 2-hydroxy-acid oxidase*).

glycolate oxidase an FMN-containing enzyme that oxidizes glycolate to glyoxylate in plant peroxisomes. It is now included with **2-hydroxy-acid oxidase**.

glycolic acid or (*formerly*) **glycollic acid** hydroxyacetic acid; hydroxyethanoic acid; HOCH₂–COOH; a constituent of sugar-cane juice.

glycolipid any compound containing (usually) one to four linked glycosyl residues joined by a glycosyl linkage to a lipid moiety (e.g. to a mono- or diacylglycerol, to a long-chain base such as sphingosine, or to a ceramide) or (in a bacterial glycolipid) joined in ester linkage to one or more fatty-acid molecules. The term embraces **galactolipid**. *See also cerebroside, ganglioside, lipopolysaccharide.*

glycollate *an obsolete variant spelling of glycolate.*

glycoloyl *symbol:* Gc; the acyl group, HOCH₂–CO–, derived from **glycolic acid**.

glycolytic pathway or Embden–Meyerhof(–Parnas) pathway the widely distributed, cytosolic, metabolic pathway by which sugars, sugar phosphates, or their precursors are broken down with an overall negative free energy change favourable to formation of ATP; the pathway yields usually pyruvate aerobically or lactate anaerobically in animal tissues. By extension, the term is also used of similar processes in other organisms yielding, sometimes, other products, e.g. ethanol, glycerol, etc. Overall there is a net yield of 2 ATP for each glucose metabolized, since phosphorylation of the hexose substrates requires 2 ATP, but conversion to pyruvate of the two 3-carbon substrates formed yields 2 ATP for each. The pathway from glucose involves its conversion to glucose 6-phosphate, thence successively to fructose 6-phosphate, fructose 1,6-bisphosphate, glyceraldehyde 3-phosphate plus glycero phosphate (which is converted to glyceraldehyde 3-phosphate in situations in which it is further degraded), 1,3-bisphosphoglycerate, 3-phosphoglycerate, 2-phosphoglycerate, phosphoenolpyruvate, and pyruvate. The enzymes involved are hexokinase, glucose-6-phosphate isomerase, phosphofructokinase, fructose-bisphosphate aldolase, triose-phosphate isomerase, glyceraldehyde-3-phosphate dehydrogenase, phosphoglycerate kinase, phosphoglycerate mutase, enolase, and pyruvate kinase (*see individual entries*). Glycogen breakdown (**glycogenolysis**) by phosphorylase yields glucose 1-phosphate, which is converted by phosphoglucomutase to glucose 6-phosphate, which in muscle is then degraded by the pathway outlined above. The pathway is subject to hormonal regulation, especially by insulin, glucagon, and epinephrine. Flux through the pathway is under powerful regulation by phosphofructokinase, the main modulator of which is **fructose 2,6-bisphosphate**.

glycolytic oscillator any metabolic activity that produces periodic regular oscillations in the concentrations of intermediates of the **glycolytic pathway**, as observed in glycolysing yeast cells and extracts of

skeletal muscle and heart. These oscillations reflect periodic changes in the activity of **phosphofruktokinase** in response to changes in the levels of its activators and inhibitors.

glycome the full array of polysaccharide chains in a cell, tissue, organ, or organism. *Compare* **proteome**.

glycomics the study of all the carbohydrate molecules that are produced by an organism.

glycon or (formerly) **glycone** the carbohydrate moiety of any **glycoside** that also contains a noncarbohydrate component.

glyconeogenesis 1 an alternative name for **gluconeogenesis 2** (sometimes) the formation of glycogen from noncarbohydrate precursors.

glyconic acid an *obsolescent* name for **aldonic acid**.

glycopeptide any compound in which carbohydrate is covalently attached to an oligopeptide composed of residues of L- and/or D-amino acids. The term usually denotes a product of proteolytic degradation of a glycoprotein, but includes glycated peptide. It should be distinguished from **peptidoglycan**, for which it is sometimes considered to be a synonym.

glycophorin any of several type I membrane proteins of the erythrocyte membrane. They are carbohydrate-rich sialoglycoproteins (SGPs – hence the nomenclature for glycophorins: αSGP, etc.), and stain with periodic acid–Schiff (PAS) reagent (hence the nomenclature PAS 1, etc. for bands on electrophoresis). The glycosylated moiety serves as an antigenic determinant and as a receptor for viruses and plant agglutinins. A glycophorin was the first membrane protein to have its full sequence elucidated. There is a single membrane-spanning domain. **Glycophorin A** (or αSGP) is the major sialoglycoprotein of the human erythrocyte membrane. On electrophoresis, it occurs in PAS 1 (dimer). It has a molecular mass of ~31 kDa, contains 60% carbohydrate by weight, and consists of a 131-residue polypeptide chain that spans the cell membrane; all the carbohydrate is attached to the N-terminal half, and is exposed to the exterior of the cell. Glycophorin A displays either M or N blood group activity (*see* **MNSs system**), depending on which of two alternative pairs of amino-acid residues occurs at positions 1 and 5 in the sequence. It binds influenza virus. **Glycophorin B** (or δSGP), also from the human erythrocyte membrane, is a minor sialoglycoprotein, similar to glycophorins A and E. It occurs in PAS 3, and has an amino-acid sequence identical in its N-terminal segment to that of glycophorin A_N. It carries the immunodeterminants for the N and Ss antigens (*see* **MNSs system**). **Glycophorin C** (or βSGP) occurs in PAS 2, glycoconnectin; it is a minor sialoglycoprotein that probably contains blood group Gerbich antigens, and receptors for *Plasmodium falciparum* (malaria) merozoites. **Glycophorin E** is similar to glycophorins A and B.

glycoprotein a conjugated protein in which the non-protein group is a carbohydrate; the sugar moiety occurs most commonly as oligosaccharide or fairly small polysaccharide, but occasionally as monosaccharide. Glycoproteins are widespread in animals and in the primary cell walls of plants. The term includes glycated protein, and is now considered also to include **proteoglycan**. *Compare* **muco-protein**.

glycoprotein hormone any of **follicle-stimulating hormone**, **lutening hormone**, and **thyroid-stimulating hormone** produced by the pituitary, and **chorionic gonadotropin**, produced by the placenta, all of which are heterodimers of glycosylated α and β subunits. In any given species, the amino-acid sequences of the α subunits are identical, or nearly so, whereas the β subunits have greater differences in amino-acid sequence and confer hormonal specificity on the molecules.

glycoprotein Ib *abbr.*: GP-Ib; a surface membrane protein of platelets that participates in the formation of platelet plugs by binding to von Willebrand factor. It is a disulfide-linked heterodimer of α and β subunits.

glycoprotein IIb/IIIa *abbr.*: GpIIb/IIIa; a major glycoprotein complex of the platelet surface. GpIIb consists of a heavy chain (containing seven homologous repeats that form a beta propeller and including four Ca²⁺-binding sites) linked by a disulfide bond to a membrane-anchored light chain. Both chains are derived by cleavage from a precursor (1039 amino acids). GpIIIb (762 amino acids) contains five cysteine-rich regions and a transmembrane segment.

On activation, e.g. by thrombin, the complex binds fibrinogen, fibronectin, and **von Willebrand factor**. Numerous mutations in GpIIb and in GpIIIa cause Glanzmann thrombasthenia.

glycoprotein N-palmitoyltransferase EC 2.3.1.96; an enzyme that catalyses a reaction between palmitoyl-CoA and a glycoprotein to give N-palmitoylglycoprotein with release of CoA.

glycosaemia a variant spelling (*esp. Brit*) of glycosemia (*see* **glycemia**).

glycosamine an older name for **aminodeoxysugar**, now restricted to some trivial names. *Distinguish* from **glycosylamine**.

glycosaminoglycan any glycan (i.e. polysaccharide) containing a substantial proportion of aminomonosaccharide residues.

glycosaminopeptide an alternative name for **peptidoglycan**.

glycosan an old term (*not recommended*) for any anhydrosugar whose formation involves its reducing group. *Distinguish* from **glycan**.

glycose 1 a less frequently used term for any monosaccharide. **2** an obsolete name for **glucose** (*see also* **glyco+** (def. 2)). **3** (sometimes) an alternative name for **corn syrup**.

glycosemia or (*esp. Brit*) **glycosaemia** an alternative name for **glycemia**.

glycosidase any hydrolase of subclass EC 3.2, enzymes that hydrolyse glycosidic linkages. Glycosidases are subdivided into those that hydrolyse O-glycosyl compounds (EC 3.2.1), N-glycosyl compounds (EC 3.2.2), or S-glycosyl compounds (EC 3.2.3). Some glycosidases can also transfer glycosyl residues to oligosaccharides, polysaccharides, or other acceptor alcohols. *See also* (**DNA**) **glycosylase**, **glucosidase**.

glycoside or **oside 1** any compound in which a **glycosyl** group is substituted into a hydroxyl group, a thiol group, or a selenol group in another compound; such a substance may be named, respectively, O-glycoside, S-glycoside (or thioglycoside), or Se-glycoside (or selenoglycoside). A glycoside is either a mixed acetal (if derived from a cyclic form of an aldose) or a mixed ketal (if derived from a cyclic form of a ketose). By extension, any compound formed by attachment of a glycosyl group to a hydrocarbyl group has been termed a C-glycoside and that by attachment of a glycosyl group to an amino or substituted amino group has been termed also N-glycoside (or nitrogen glycoside), but these terms are misnomers and should not be used; the preferred terms are **C-glycosyl compound** and **glycosylamine**, respectively. *See also* **cardiac glycoside**, **nucleoside**. **2** an obsolete term for **glucoside**.

glycosidic 1 of, pertaining to, or being a **glycoside**. **2** an alternative term for **anomeric** (def. 2).

glycosidic bond the covalent bond between the anomeric carbon atom of a saccharide and some other group or molecule with which it forms a glycoside.

glycosiduronate 1 the anion of a **glycosiduronic acid**. **2** any salt or ester of a glycuronic acid.

glycosiduronic acid or (formerly) **glycuronide** a glycoside of any **uronic acid**.

glycosome a microbody-like organelle present in *Trypanosoma brucei* and containing nine enzymes involved in glycolysis, and glycerol kinase.

glycosphingolipid any compound containing residues of a sphingoid and at least one monosaccharide. Glycosphingolipids are subdivided into: (1) neutral glycosphingolipids, comprising monoglycosyl- and oligoglycosylsphingoids and monoglycosyl- and oligoglycosylceramides; and (2) acidic glycosphingolipids, comprising sialosylglycosylsphingolipids (**gangliosides**) and sulfoglycosylsphingolipids (formerly known as sulfatides).

glycostatic maintaining a constant level of sugar, e.g. of glucose or glycogen. *Compare* **glycotropic**.

glycosuria the presence of abnormally high concentrations of glucose and/or other sugars in the urine. *See also* **glucosuria**, **fructosuria**.

glycosyl any chemical group formed by detaching the anomeric, i.e. glycosidic, hydroxyl group from the cyclic form of a monosaccharide or monosaccharide derivative, or (by extension) of a lower oligosaccharide or oligosaccharide derivative.

glycosylamine any compound formed by the replacement of the anomeric, i.e. glycosidic, hydroxyl group of a cyclic form of a monosaccharide or monosaccharide derivative by an amino group

or a substituted amino group. (The term **nitrogen glycoside** (or *N*-glycoside) is a misnomer for glycosylamine and should not be used.) *Distinguish from glycosamine.*

glycosylamino acid any **glycoamino acid** in which the saccharide moiety is in glycosyl (*O*-, *N*- or *S*-) linkage to the amino-acid moiety. These are obtained by enzymic or chemical cleavage of glycoproteins, or by chemical or enzymic synthesis.

glycosylase *see* (DNA) **glycosylase**.

glycosylasparaginase *see* **N⁶-(β-N-acetylglucosaminy)-L-asparaginase**.

glycosylated hemoglobin a misnomer for **glycated hemoglobin**.

glycosylation substitution of one or more **glycosyl** groups into a chemical compound or group. *See also* **glycation**. —**glycosylated** *adj.*

C-glycosyl compound any compound formed by the replacement of the anomeric, i.e. glycosidic, hydroxyl group of a cyclic form of a monosaccharide or monosaccharide derivative by an organyl group. The term *C*-glycoside is a misnomer for *C*-glycosyl compound and should not be used.

glycosyloxy any chemical group formed by detaching the hydrogen atom from the anomeric, i.e. glycosidic, hydroxyl group of the cyclic form of a monosaccharide or monosaccharide derivative.

glycosylphosphatidylinositol *see* **GPI anchor**.

glycosyltransferase *abbr.*: GT; any enzyme transferring a glycosyl group. Glycosyltransferases belong to subclass EC 2.4, which includes hexosyltransferases (EC 2.4.1.1 to 2.4.1.206); pentosyltransferases (EC 2.4.2.1 to 2.4.2.37); and enzymes transferring other glycosyl groups (EC 2.4.99.1 to 2.4.99.11).

glycotropic increasing the concentration of glucose in the blood. *Compare* **glycostatic**.

glycuronan or (formerly) **polyuronide** any glycan composed entirely of uronic-acid residues.

glycuronic acid an obsolete term for **uronic acid**.

glycuronide the former term for **glycosiduronic acid**.

glycyl the acyl group, NH₂-CH₂-CO-, derived from **glycine**.

glycyl chain a name sometimes applied to the **A chain** of any of those species of insulin whose amino-acid sequences were the first to be determined. It is so-called by virtue of the N-terminal glycine residue occurring in those instances.

glycylglycine a dipeptide useful for the preparation of buffers in the pH range around its pK_a (20 °C) of 8.40.

glycyrrhiza also called **liquorice** or (*esp. US*) **licorice**; a preparation obtained from the dried roots of the leguminous shrub, *Glycyrrhiza glabra*, with flavouring and medical uses.

glycyrrhizic acid 20β-carboxy-11-oxo-30-norolean-12-en-3β-yl-2-*O*-β-D-glucopyranuronosyl-α-D-glucopyranosiduronic acid; a glycosiduronic acid extracted from *glycyrrhiza* (*see* **glycyrrhiza**); it has an intensely sweet taste.

glyoxal ethanedial; OHC-CHO; also called **diformyl**; the dialdehyde analogue of glycol and oxalic acid. It is sometimes used to replace formaldehyde in **denaturing agarose gel electrophoresis** of RNA. The basis of denaturation is the formation of an adduct with the imino groups of guanosine.

glyoxalase I EC 4.4.1.5; *recommended name*: lactoylglutathione lyase, *other name*: methylglyoxalase. An enzyme catalysing the reaction:

glyoxalase II EC 3.1.2.6; *recommended name*: hydroxyacylglutathione hydrolase. An enzyme catalysing the reaction:

glyoxalate a former name for **glyoxylate**.

glyoxaline an alternative name for **imidazole**.

glyoxylate or (formerly) **glyoxalate I** the anion, OHC-COO⁻, derived from glyoxylic acid. **2** any salt or ester of glyoxylic acid.

glyoxylate cycle or **glyoxylate pathway** a modification of the **tricarboxylic-acid cycle** occurring in some plants and microorganisms, in which isocitrate, instead of being dehydrogenated, is cleaved as described under **isocitrate lyase** to glyoxylate and succinate. This serves to generate glyoxylate from the acetyl moiety of acetyl-CoA. The glyoxylate can then react with another molecule of acetyl-CoA to

form malate, a reaction catalysed by **malate synthase**. These two reactions taken together allow a four-carbon molecule, malate, and hence carbohydrate, to be formed from acetyl-CoA, which, in turn, may be formed from fatty acids. In some plants the enzymes of the glyoxylate pathway are present in **glyoxysomes**.

glyoxysome a cellular organelle, of density 1.25 gm⁻³, found in the organs of fatty seedlings where fat is being converted to carbohydrate. It contains the enzymes of the **glyoxylate cycle** and most of the particulate beta-oxidation activity.

glyphosate *N*-(phosphonomethyl)glycine; a potent, systemically acting, nonselective herbicide, present as its isopropylamine salt in some commercial weedkillers. It functions by inhibiting 5-enolpyruvylshikimate-3-phosphate (EPSP) synthase. *See also* **shikimate**. *Proprietary names* include Roundup and Tumbleweed.

glypiation the attachment or process of attachment of glycosylphosphatidylinositol to proteins. *See* **GPI anchor**.

glypican any of a family of heparan sulfate proteoglycans that are linked to the cell surface via a GPI anchor. Their core proteins (60–70 kDa) have attachment sites for heparan sulfate chains within the 50 C-terminal residues and, N-terminal to these sites, a conserved globular cysteine-rich domain. They are involved in development and morphogenesis. At least six members occur in mammals and two in *Drosophila*. Mutation in glypican-3 causes the X chromosome-linked Simpson-Golabi-Dahmel syndrome type 1, characterized by overgrowth, dysmorphism, and anomalies of the skeleton, heart, gastrointestinal tract, and central nervous system.

GM or **G-M** *abbr.* for Geiger-Müller (e.g. in **GM counter** for Geiger-Müller counter).

GM-CSF *abbr.* for granulocyte/macrophage colony stimulating factor. *See* **colony stimulating factor**.

GMD (*in clinical chemistry*) *abbr.* for **glutamate dehydrogenase (NAD(P)⁺)**.

GMP *abbr.* for guanosine monophosphate i.e. guanosine phosphate.

GMP synthase EC 6.3.5.2; *recommended name*: GMP synthase (glutamine-hydrolysing); *systematic name*: xanthosine-5-phosphate:L-glutamine amido-ligase (AMP-forming); *other names*: GMP synthetase (glutamine-hydrolysing); glutamine amidotransferase. An enzyme that catalyses a reaction between ATP, xanthosine 5'-phosphate, L-glutamine, and H₂O to form AMP, pyrophosphate, guanosine monophosphate, and L-glutamate. It is inhibited by azaserine and 6-diazo-5-oxonorleucine, in common with other glutamine amidotransferases. It has four motifs and a region conserved in amidotransferases (one motif).

GMT (*in clinical chemistry*) *abbr.* for **glutamyltransferase**.

GNAT *abbr.* for GCN5-related N-acetyltransferase. The GNAT superfamily is one of five families of histone acetyltransferase, a class of enzyme that catalyses the transfer of an acetyl group from acetyl-CoA to the lysine ε-amino groups on the N-terminal tails of histones. GNATs share various functional domains (e.g., a variable-length N-terminal region, an acetyltransferase domain, a coactivator interaction region, and a C-terminal bromodomain) and are involved in transcription and DNA repair, and hence play important roles in the regulation of cell growth and development.

gnotobiotic describing an organism, especially a higher animal, or its environment, that has been deliberately rendered free of microorganisms and other organisms, including parasites, commensals, and symbionts, that it would normally harbour, or that harbours only a few, known, such organisms.

GnRH *abbr.* for gonadotropin-releasing hormone.

GNTR a transcriptional repressor for the gluconate (*gnt*) operon in *Bacillus subtilis*. The *gnt* operon is induced by gluconic acid δ-lactone; this was the first of a family of *gnt* repressors with **helix-turn-helix** motifs.

GNU *abbr.* for Gnu is Not Unix; a humorous recursive title for a very large open source software project that is an important source of academic software and the GNU Public Software License (known as 'copyleft', in contrast to copyright). This is widely used for free software distribution on terms that are well tested particularly under US jurisdiction.

GO *abbr.* for gene ontology.

goblin a protein of avian erythrocyte plasma membranes, *M_r* 260

000. It undergoes phosphorylation, and is highly similar to **ankyrin**, of which it is the avian equivalent.

GOD 1 (sometimes) *abbr.* for glucose oxidase. **2** *abbr.* for generation of diversity.

godnose a name proposed for ascorbic acid by A. Szent-Györgyi, as an alternative to **ignose**, before he knew its structure.

GOGAT *abbr.* for glutamine (amide):2-oxoglutarate aminotransferase (oxidoreductase NADP⁺). It comprises two separate enzymes, named **glutamate synthase (ferredoxin)** and **glutamate–ammonia ligase**.

goitre or (*US*) **goiter** any swelling of the thyroid gland. Although common in areas where dietary iodine is insufficient, the condition is not related to thyroid state and patients with goitre may be euthyroid, hyperthyroid, or hypothyroid.

goitrogen any agent or factor causing goitre.

GOLD *abbr.* for genomes online database.

Gold book *informal name* for the IUPAC *Compendium of Chemical Terminology*, in recognition of the contribution of Victor Gold (1922–1985), who initiated work on the first edition.

Golgi apparatus or **Golgi body** or **Golgi complex** or **Golgi** a compound membranous cytoplasmic organelle of eukaryotic cells, consisting of flattened, ribosome-free vesicles arranged in a more or less regular stack. It differs from the endoplasmic reticulum in often having slightly thicker membranes, appearing in sections as a characteristic shallow semicircle so that the convex side (*cis* or entry face) abuts the endoplasmic reticulum, secretory granules emerging from the concave side (*trans* or exit face). In vertebrate cells there is usually one such organelle, while in invertebrates and plants, where they are known usually as **dictyosomes**, there may be several scattered in the cytoplasm. The Golgi apparatus processes proteins produced on the ribosomes of the rough endoplasmic reticulum; such processing includes modification of the core oligosaccharides of glycoproteins, and the sorting and packaging of proteins for transport to a variety of cellular locations, e.g. to storage granules, lysosomes, or secretory vesicles. The Golgi is a major site of synthesis of polysaccharides, including the **pectin** and hemicellulose of the plant cell wall and most of the glycosaminoglycans of the extracellular matrix in animals. Three different regions are recognized in terms of structure and function: *cis*, in the vicinity of the *cis* face, *trans*, in the vicinity of the *trans* face, and *medial*, lying between the *cis* and *trans* regions. While the **luminal proteins** of the endoplasmic reticulum leave it together with the proteins to be secreted, they are retrieved from the *cis* network and returned to the endoplasmic reticulum. Thus transport occurs in both directions. **Brefeldin A** blocks protein secretion through the Golgi but does not appear to block the return pathway. **Galactosyltransferase** is a marker enzyme for the *trans* membranes while **N-acetylglucosaminyltransferase III** serves this role for the medial membranes. [After Camillo Golgi (1843–1926), Italian anatomist, cytologist, neurologist, and pathologist, who, in 1898, was the first to describe it.]

Golgi mannosidase EC 3.2.1.114; *recommended name*: mannosyl-oligosaccharide 1,3-1,6- α -mannosidase; *systematic name*: 1,3-(1,6-)mannosyl-oligosaccharide α -D-mannohydrolase; *other name*: mannosidase II. An enzyme that catalyses the hydrolysis of the terminal 1,3- and 1,6-linked α -D-mannose residues in the mannosyl-oligosaccharide Man₅GlcNAc₃. It is a type II membrane protein, and a glycosyl hydrolase enzyme in all tissues, mostly in adrenal and thymus. It belongs to a family of glycosyl hydrolases.

golgin any protein from the Golgi apparatus that is identified as an antigen in autoimmune conditions. The normal function of golgins may be to maintain the structure of the apparatus or to participate in membrane trafficking. *See* **giantin**.

golgiosome *an alternative name for dictyosome*.

GoLoco motif a 20-residue protein sequence in some proteins that regulate G-protein signalling via G_{α0} and G_{αi}. It is present in two proteins required for asymmetric spindle positioning in *Caenorhabditis elegans* embryos.

gonad any animal organ that produces gametes. In some species the gonads also produce hormones. —**gonadal adj.**

gonadoliberin *recommended name for gonadotropin-releasing hormone*.

gonadotropic hormone or **gonadotrophic hormone** *a former name for gonadotropin*.

gonadotropin or (*formerly*) **gonadotrophin** or **gonadotrophic hormone** or **gonadotrophic hormone 1** any mammalian glycoprotein hormone that stimulates gonadal function. Strictly, gonadotropins comprise the adenohipophyseal hormones **follicle-stimulating hormone** (FSH) and **luteinizing hormone** (LH) together with the placental hormone **choriogonadotropin**, but the term is often extended to include also the adenohipophyseal hormone **prolactin** (which is not a glycoprotein but has gonadotropic activity). **2** any single substance having the combined activities of FSH and LH, such as **choriogonadotropin** or the gonadotropic hormones of cold-blooded vertebrates. **3** any impure hormonal preparation displaying the separate activities of FSH and LH, such as (human) menopausal gonadotropin (i.e. urogonadotropin) and **pregnant mare's serum gonadotropin**. —**gonadotropic adj.**

gonadotropin-releasing factor *abbr.*: GnRF; *another name for gonadotropin-releasing hormone*.

gonadotropin-releasing hormone (*abbr.*: GnRH) or **gonadoliberin** (recommended name) or **luteinizing hormone/follicle-stimulating hormone releasing factor** (*abbr.*: LH/FSH-RF) a family of decapeptide amides containing at least seven members and present in many vertebrate species from jawless fish (lamprey) to higher mammals. The structure is highly conserved; the sequence Gln-His-Trp-Ser-Tyr-Gly-Leu-Arg-Pro-Gly-NH₂ is common to all mammals; among other species, position 8 is most variable, positions 1, 2, 4, 9, and 10 being invariant. In mammals it is released by the hypothalamus, where it localizes with galanin, into the hypophyseal portal circulation in response to neural and/or chemical stimuli, and causes the release of FSH and LH by the anterior pituitary. It is also expressed in the placenta, and may act as a neurotransmitter, neuromodulator, or local hormone. It is derived from a larger precursor. For example, the rat precursor protein consists of 93 amino acids; residues 24–33 form GnRH and residues 37–92 form a peptide (GnRH-associated peptide, *abbr.*: GAP) that is poorly conserved and of unclear function. *See* **KAL**.

gonadotropin-releasing hormone receptor *abbr.*: GnRHR; any of a family of G-protein-associated membrane receptors that bind gonadotropin-releasing hormone (GnRH) and stimulate the phosphatidylinositol Ca²⁺ second messenger system. They are present in pituitary, ovary, testis, breast, and prostate.

gonane the parent 17-carbon tetracyclic hydrocarbon of steroids and bile acids.

gondoic acid *see eicosenoic acid*.

gonosome any motile animal germ cell, e.g. a spermatozoon.

Good buffer substance or **Good's buffer (substance)** any member of a collection of **zwitterionic buffer** substances selected or devised for suitability in experimental biological systems according to a number of predetermined criteria. These include: ease of preparation and purification; high solubility in water; low temperature coefficient of pK_a; and high transparency to light or ultraviolet light of wavelengths greater than 230 nm. The original lists included substances having the following trivial names (pK_a values at 20°C are in parentheses): **Mes** (6.15), **Ada** (6.6), **Pipes** (6.8), **Aces** (6.9), **Bes** (7.15), **Mops** (7.2), **Tes** (7.5), **Hepes** (7.55), **Hepps** (8.0), **Tricine** (8.15), **Bicine** (8.35), and **Taps** (8.4); **Ches** (9.3 at 25°C) and **Caps** (10.4) have similar properties. [After Norman Everett Good (1917–), US plant pathologist.]

gossypol a pigment found in cottonseed and containing two naphthalene rings with multiple –OH and other groups. It has antispermatogenic activity, and has been used (in China) as a male contraceptive. It is a potent inhibitor of contractions of strips of guinea-pig lung induced by platelet-activating factor or leukotriene, and it inhibits 5- and 12-lipoxygenase.

GOT (*in clinical chemistry*) *abbr.* for glutamate-oxaloacetate transaminase (AST preferred). *See* **transaminase**.

Goto-Kakizaki rat a strain of laboratory rats that have an inherited predisposition to develop diabetes. [Named after Y Goto and M Kakizaki, Tohoku University, Japan.]

gout a condition characterized by inflammation of the joints and cartilage due to hyperuricemia and consequent deposition of monosodium urate crystals in the joints, often within polymor-

phonuclear leukocytes. The hyperuricemia results from overproduction of uric acid, which may be due to elevated activity of ATP phosphoribosyltransferase (PRPP synthetase; EC 2.4.2.17), an abnormal **amidophosphoribosyltransferase**, or deficiency of hypoxanthine phosphoribosyltransferase (EC 2.4.2.8). **Allopurinol** is useful in treatment.

gp *abbr.* for glycoprotein used in conjunction with the relative molecular mass (e.g. gp115).

gp32 an envelope glycoprotein from HIV-related viruses, including SIV types. *See* **HIV protein**.

gp96 *abbr.* for glycoprotein of 96 kDa; *other name:* glucose-regulated protein of 94 kDa (*abbr.:* Grp94); an abundant molecular chaperone glycoprotein endoplasmic reticulum, and an orthologue of heat shock protein 90 (Hsp90).

G1P or **G-I-P** *abbr.* for glucose 1-phosphate.

G6P or **G-6-P** *abbr.* for glucose 6-phosphate.

G-patch a conserved protein sequence of ≈ 48 residues that contains six highly conserved glycine residues. It is present in some eukaryotic RNA-processing proteins and certain retroviral polyproteins. It usually occurs singly, and is often associated with other RNA-binding sequences.

GPCR *abbr.* for G-protein-coupled receptor.

GPD (*in clinical chemistry*) *abbr.* for glucose-6-phosphate dehydrogenase.

G₀ phase G-'zero' phase; a state of withdrawal from the eukaryotic **cell-division cycle**. It occurs if no stimulus for cell division occurs during G₁ phase, leaving the cell in a quiescent G₁ phase. It is often seen in differentiated cells.

G₁ phase Gap 1 phase; the phase of the eukaryotic **cell-division cycle** between the end of **cytokinesis** and the start of DNA synthesis, i.e. the gap between M phase and S phase.

G₂ phase Gap 2 phase; the phase of the eukaryotic **cell-division cycle**, between the end of DNA synthesis and the beginning of mitosis, i.e. the gap between S phase and M phase.

GPI (*in clinical chemistry*) *abbr.* for glucose-6-phosphate isomerase.

GPI anchor *abbr.* for glycosylphosphatidylinositol anchor; a molecular mechanism for attaching a membrane protein to the lipid bilayer of a cell membrane. Structurally it consists of a molecule of phosphatidylinositol (*abbr.:* PI) to which is linked, via the C-6 hydroxyl of the inositol, a carbohydrate chain. This chain is in turn linked to the protein through an ethanolamine phosphate moiety, the amino group of which is in amide linkage with the C-terminal carboxyl of the protein chain, the phosphate group being esterified to the C-6 hydroxyl of the terminal mannose of the core carbohydrate chain. The carbohydrate chain varies in composition between species, but invariably contains a core tetrasaccharide, the first component of which is a glucosamine residue in glycosidic linkage with the inositol C-6 hydroxyl. The tetrasaccharide has the structure Man(α 1-2)Man(α 1-6)Man(α 1-4)GlcNH₂. Variation frequently occurs in the presence of additional α -mannose residues on the anchors of *Trypanosoma cruzi*, yeast, slime mould, and mammalian proteins. Anchors of *Trypanosoma brucei* have more elaborate carbohydrate side-chains containing galactose, glucosamine, and sialic-acid residues. In the case of metazoan eukaryotes, additional ethanolamine phosphate substituents may occur on mannose residues, and the inositol is often palmitoylated. Biosynthesis begins with attachment of the glucosamine moiety to phosphatidylinositol, followed by sequential addition of other sugars; the GPI moiety is attached to protein during processing in the endoplasmic reticulum, the signal being a hydrophobic sequence at the C terminus, which is removed during the attachment process. GPI-anchored proteins are released from membranes by PI-specific phospholipases. While the general function of the GPI anchor is to anchor the protein to the membrane, wider functions may include: location of the protein at specific sites, particularly the apical membrane of polarized epithelial cells; promotion of sequestration into membrane microdomains, these proteins being excluded from clathrin-associated regions but found in **caveolae**; anchoring of proteins of the glycocalyx, and cell signalling and cell recognition proteins. In addition to protein-linked GPIs, *Leishmania* spp. also synthesize two classes of free GPIs, the polydisperse **lipophosphoglycans** (LPGs) and the low molecular mass **glycoinosi-**

tolphospholipids (GIPLs). LPGs are restricted in occurrence (e.g. promastigote stage) but GIPLs are relatively abundant on the cell surface of promastigote and amastigote stages. GIPLs are also found on the surface of many other trypanosomatid parasites, e.g. *T. cruzi*, *Leptomonas*, *Herpetomonas*, and *Phytomonas*.

gp22-phox *see* **phagocyte NADPH oxidase**.

gp91-phox *see* **phagocyte NADPH oxidase**.

gp 43 processing protease *see* **oviductin**.

G protein guanine nucleotide binding protein; any heterotrimeric GTP-binding and hydrolysing protein belonging to a superfamily of GTPases that includes the monomeric proteins EF-Tu (*see* **EF-T**) and p21^{ras} (*see* **RAS**). G-proteins participate in activation or inhibition of **adenylate cyclase** and other **second messenger** systems, e.g. **phosphatidylinositol cycle**. They are associated with membrane receptors that contain seven transmembrane helices and bind hormones, growth factors, and cytokines. The system is unique to eukaryotes. G-proteins consist of three subunits; the α subunit (39–46 kDa) contains the guanine nucleotide binding site and possesses GTPase activity; the β (37 kDa) and γ (8 kDa) subunits are tightly associated and function as a β gamma; heterodimer. There are 23 types (including some splicing isoforms) of α subunits, 6 of β , and 11 of γ . The classes of G-protein and subunits are subscripted: thus the α subunit of G-protein S (which activates **adenylate cyclase**) is G_{S α} ; other G-proteins include G_i, which differs from G_S structurally (different type of α subunit) and inhibits **adenylate cyclase**; G_o, a G-protein detected by cDNA probes, of wide tissue distribution in mammals but of unclear role; G_p, a G-protein that activates phospholipase C (*see* **phospholipase**), release of Ca²⁺ and activation via **calmodulin** and **protein kinase C** (*see also* **phosphatidylinositol cycle**). Binding of G _{$\alpha\beta\gamma$} to liganded receptor occurs when GDP bound to the G-protein ($\alpha\beta\gamma$ -GDP) exchanges for GTP, which causes the heterotrimer to dissociate into α -GTP and β gamma; units, either of which may interact with an effector. The GTPase activity of α yields α -GDP, which inactivates it. α -GDP has a high affinity for β gamma; thus reforming $\alpha\beta\gamma$ -GDP, which becomes available for association with an activated receptor. G_T, *see* **transducin**. In some tissues heterotrimeric G-proteins may be present in tight complexes that include: membrane receptor, adenylate cyclase, cAMP-dependent protein kinase, calcium channel, and a phosphoprotein phosphatase.

G protein-coupled receptor (*abbr.:* GPCR) or **G protein-associated receptor** or **G protein-linked receptor** member of a diverse family of cell-surface proteins that has adapted a common heptahelical framework to mediate a range of physiological processes (e.g., vision, olfaction, chemotaxis). Their functional diversity is achieved via interactions with a variety of ligands (e.g., peptides, glycoproteins, small molecule messenger molecules, vitamin derivatives), the effects of which stimulate a range of intracellular pathways through coupling to different G proteins. GPCRs are medically very important – they are involved in several major pathophysiological conditions (e.g., cardiovascular disease, cancer, obesity), and are the targets of the majority of prescription drugs. *See* **G protein**.

gpt *symbol* for a prokaryotic gene for xanthine–guanine phosphoribosyltransferase. It is used as a dominant selectable marker in transfection of mammalian cells with exogenous DNA. Its expression enables mammalian cells to grow in the presence of **mycophenolic acid** in a medium supplemented with xanthine.

GPT (*in clinical chemistry*) *abbr.* for glutamate–pyruvate transaminase (EC 2.6.1.2) (ALT preferred).

G-quartet or **G-tetrad** a cyclic H-bonded array of guanines that can occur in both RNA and DNA to form a quadruple helix structure. Sequences that form such structures are found in telomeric sites, the switch regions of immunoglobulin heavy-chain genes, and elsewhere. *See* **KEM1**.

Gra *symbol* for a residue of **glyceraldehyde**.

Graafian follicle a spherical vesicle occurring in the mature mammalian ovary and in which the ovum develops. When the ovum matures it is discharged after rupture of the follicle, which is then transformed into a **corpus luteum**. [After Reijnier (Regnier) de Graaf (1641–73), Dutch physician and anatomist.]

grade 1 a degree or position in a scale, as of quality, size, etc., e.g.

analytical grade, commercial grade. **2** a unit of angle equal to one-hundredth of a right angle, i.e. 0.9° .

gradient the change in the value of a specified (chemical or physical) property or value per unit distance in a specified direction.

gradient elution a chromatographic elution procedure in which the concentration of a component of the eluent is increased continuously. The gradient may be linear, concave – i.e. increasing slowly at first and more rapidly as elution proceeds – or convex – i.e. increasing rapidly at first and more slowly as elution proceeds. More complex or discontinuous (stepped) elution gradients are sometimes used.

gradient former or **gradient mixer** any device for producing solutions of varying, but defined, composition containing one or more components.

gradient gel electrophoresis or **gradient acrylamide gel electrophoresis** or **polyacrylamide gradient gel electrophoresis** (*abbr.*: PAGE) a type of **zone electrophoresis** in which the supporting medium is a pore-gradient gel, i.e. one where an increasing concentration of polyacrylamide in the direction of electrophoretic mobility decreases the sizes of the pores in the gel in that direction to the point where molecules of more than a certain size are prevented from moving further in the electric field. The concentration gradient may be either discontinuous, i.e. stepped, or continuous. Advantages of the technique over electrophoresis in uniform gels (*see gel electrophoresis*) are sharper zones and an ability to resolve, on a single gel, mixtures of macromolecules of a wider range of sizes.

gradient layer or **gradient packing** a chromatographic layer, or column packing, incorporating a continuous change of some property that affects separations, e.g. a pH gradient or a pore gradient.

graft 1 any part of an organism, animal or plant, that is inserted into and unites with a larger part of another or the same organism. **2** to transplant (tissue) to another organism or to another site on the same organism.

graft versus host disease a condition where immunocompetent donor cells recognize and react against the recipient's tissues, because the recipient is immunosuppressed or cannot recognize the different genetic constitution of the donor cells.

Graham's law of diffusion a law stating that at equal temperatures and pressures the rates of diffusion of gases are inversely proportional to the square roots of their densities and hence to the square roots of their relative molecular masses (M_r s). Thus for two gases *A* and *B*,

$$J_A/J_B = \bar{v}_A/\bar{v}_B = M_{rB}^{1/2}/M_{rA}^{1/2},$$

where J_A and J_B , \bar{v}_A and \bar{v}_B , and M_{rA} and M_{rB} are the fluxes, mean velocities, and relative molecular masses of *A* and *B*, respectively. [After Thomas Graham (1805–69), Scottish chemist.]

grain 1 any small, hard particle, e.g. a grain of sand. **2** any simple single-seeded indehiscent fruit in which the seed wall fuses with the carpel wall during development. Technically called a **caryopsis**, it is typical of the cereals and other grasses. **3** (*in photography*) any of the many particles of silver halide in a photographic emulsion. The resolution possible in the image is inversely proportional to the grain size in the emulsion. **4** any of the dried insect bodies present in dyes such as cochineal.

gram *symbol*: g; a unit of mass equal to a thousandth part of the kilogram in both the Système International (SI) and the metric system (cgs or mks) of units.

+gram *comb. form* indicating a drawing, something written or recorded; the record produced by an instrument, e.g. spectrogram; the visible result of a procedure, e.g. autoradiogram, chromatogram.

gram-atom or **gram-atomic weight** *abbr.*: g-atom; the atomic weight of an element expressed in grams; it has now been replaced by amount of substance, measured in moles.

gram-equivalent or (*formerly*) **gram-equivalent weight** *abbr.*: g-equiv; an equivalent (def. 3) expressed in grams.

gramicidin any of a group of linear polypeptide antibiotics that are active against Gram-positive microorganisms and are isolated from cultures of *Bacillus brevis*. The commercial material is a mixture of gramicidins A, B, C, and D, all of which consist of chains of 15 amino-acid residues in a pattern of alternating D- and L-forms; all

have a formyl group at the N terminus and an ethanolamine residue at the C terminus. Gramicidins increase the permeability of biological membranes to protons and alkali-metal cations by forming transient dimeric ionophoric channels through the membrane. Gramicidins are classified in the TC system under number 1.D.1. *See also* gramicidin S.

gramicidin S a homodetic cyclic decapeptide antibiotic, *cyclo*(-Val-Orn-Leu-DPhe-Pro-Val-Orn-Leu-DPhe-Pro-), produced by a strain of *Bacillus brevis* and active against Gram-positive bacteria. Gramicidin S is more closely related to **tyrocidins** in its biological and chemical properties than to true **gramicidins**. Its biosynthesis occurs by a mechanism that is not dependent on the presence of ribosomes or mRNA. It was the first peptide antibiotic to be chemically synthesized, and is so named because it was first isolated in Soviet Russia, where it was widely used.

gram-molecule or **gram-molecular weight** *symbol*: g-mol; the molecular weight of a compound (or element) expressed in grams; it has now been replaced by the mole.

Gram-negative describing a bacterial cell that, during **Gram staining**, does not retain the basic dye in its cell wall. The walls of Gram-negative organisms are thin, about 10 nm across, but complex, having a lipopolysaccharide layer outside the peptidoglycan layer; they are also resistant to digestion by lysozyme. *Compare* **Gram-positive**.

Gram-positive describing a bacterial cell that, during **Gram staining**, retains the basic dye in its cell wall. The walls of Gram-positive organisms are relatively thick, 15–80 nm across, and consist of a network of peptidoglycan; they are readily digested by lysozyme. *Compare* **Gram-negative**.

Gram staining or **Gram stain** a staining procedure used for bacteria in which the cells are first heat-fixed and stained with a basic dye, e.g. Crystal Violet, then treated with I_2 -KI solution to fix the stain, washed with ethanol or acetone, and finally counterstained with another dye, e.g. carbolfuchsin or safranin. Cells that retain the basic dye after this procedure are called **Gram-positive**; those that do not are called **Gram-negative**. [After Hans Christian Joachim Gram (1853–1938), Danish physician and bacteriologist, who described the method in 1884.]

grancalcin a Ca^{2+} -binding protein containing four **EF hands**, and abundant in neutrophils and monocytes. It shares strong similarity with **sorcini**. It is a homodimer.

β granin *see* **chromogranin**.

granular or **granulose** or **granulate** being composed of, or having the character of small particles or **grains** (def. 1).

granular endoplasmic reticulum or **rough endoplasmic reticulum** *see* **endoplasmic reticulum**.

granulate 1 to make (something) into **grains** (def. 1). **2** (of a wound, ulcer, etc.) to form **granulation tissue**. **3** *another word for* **granular**.

granulation 1 the act or process of subdividing a solid into small, usually rounded **grains** (def. 1). **2** the formation of one or more small, rounded lumps (grains (def. 1)) in a tissue. **3** the development of **granulation tissue**.

granulation tissue the mass of young connective tissue and blood vessels formed on the surface of a wound or ulcer in the early stages of healing.

granule any small **grain** (def. 1), especially any small intracellular particle containing stored material that can be seen by (electron) microscopy, e.g. insulin-containing β granules in the B cells of the islets of Langerhans, starch granules in potato tubers.

granulocyte a category of white blood cells distinguished by the presence of conspicuous cytoplasmic granules. Granulocytes include **neutrophils**, **basophils**, and **eosinophils**.

granulocyte-colony stimulating factor *see* **colony stimulating factor**.

granulose 1 *another word for* **granular**. **2** *an obsolete name for* **starch** or amylose.

granum (*pl.* **grana**) a stack of disclike **thylakoids** resembling a pile of coins. Grana occur in **chloroplasts**, especially in higher plants.

granzyme any of three related serine proteases (EC 3.4.21) that occur (with perforin) in cytoplasmic vesicles of killer T-lymphocytes and induce death in target cells.

granzyme A enzyme of sub-subclass EC 3.4.21; *other names*: cytotoxic T-lymphocyte protease 1; Hanukkah factor (HF); granzyme

1; CTL tryptase; fragmentin 1; trypsin-like serine protease. An enzyme necessary for target-cell lysis in cell-mediated immune responses; it cleaves on the carbonyl side of Lys or Arg. It occurs in cytoplasmic granules, and may be involved in **apoptosis**. The molecule is a disulfide-linked homodimer.

grape sugar *a former name for D-glucose. See glucose.*

graph 1 a diagram showing the relation between two variable quantities, or the relation between a mathematical function and different values of one of the variables in the function, usually plotted between axes at right angles to each other. **2** to plot or draw a graph.

+graph *comb. form 1* denoting (something) drawn, recorded, or written (in the way specified), e.g. autoradiograph, photograph. **2** denoting an instrument or device that draws or records (observations), e.g. spectrograph. **3** denoting the act or process of producing such a drawing or record. *Compare +gram. —+graphic or +graphical adj. comb. form.*

graphics (*functioning as sing.*) **1** the use of diagrams in calculation. **2** the production of diagrams, representations of molecular structures, etc., often by computer.

+graphy *comb. form* denoting a method, process, or technique that produces a drawing or record, e.g. chromatography. *See +graph.*

grating *see* diffraction grating.

gratuitous inducer any compound that causes the induction of gene expression and is not itself metabolized by the enzymes so induced. A well-known example is the induction of the *lac* operon by isopropylthiogalactoside (IPTG).

Graves' disease or **Basedow's disease** a disease characterized by diffuse goitre, thyrotoxicosis, and exophthalmia. It is an autoimmune condition associated with serum antibodies against the thyrotropin receptor. [After Robert James Graves (1796–1853), Irish physician.]

Graves' disease carrier protein *see* GDC.

gravimetric analysis quantitative analysis of the chemical composition of substances or materials based on the separation of each component of interest and weighing either the purified compound or a derivative of it.

gravimetry measurement by weighing. —**gravimetric** or **gravimetrical** *adj.*

gravitation the attractive force that bodies exert on one another as a result of their mass; any process or result caused by such an attractive force. —**gravitational** *adj.*

gravitational constant *symbol:* *G*; the proportionality constant relating the attractive force, *F*, between two bodies of mass *m*₁ and *m*₂, and the distance between them, *s*, in Newton's law of gravitation:

$$G = F s / m_1 m_2 = 6.67259(85) \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}.$$

gravitational field any field (def. 1) associated with a mass by which a force is exerted on a second mass placed in this field.

gravitational interaction any interaction between bodies or particles that results from their masses.

gravitational mass *see* mass.

gravity 1 the attractive force that moves or tends to move bodies towards the centre of any celestial body such as the earth or the moon. **2** the attribute of having weight. **3** **specific gravity**.

gray *symbol:* Gy; the SI derived unit of **absorbed dose** of radiation, equal to one joule per kilogram of living tissue;

$$1 \text{ Gy} = 1 \text{ J kg}^{-1} = 1 \text{ m}^2 \text{ s}^{-2}.$$

Compare sievert. See also rad. [After Louis Harold Gray (1905–65), British physicist and radiobiologist.]

Grb2 growth factor receptor-bound protein 2; *also called* **Ash protein**; a cytosolic adaptor protein, related to sem-5 (*see sem-5*), that participates in downstream signalling after activation of epidermal growth factor and platelet-derived growth factor receptors; it can also be recruited by G-protein-coupled receptors through tyrosine phosphorylation of Shc (*see SHC*). Grb2 binds to activated Shc and the complex then recruits Sos (*see sos*). The Shc–Grb2–Sos complex binds to the plasma membrane where Sos catalyses **Ras** guanine nucleotide exchange, leading to MAP kinase activation. Grb-10 is activated by RET.

GRE *abbr. for* glucocorticoid response element.

green fluorescent protein *abbr.:* GFP; a protein isolated from the

jellyfish, *Aequorea victoria*, that fluoresces when exposed to excitation light (there are several spectral variants, including yellow, cyan, blue, and red). GFP has important applications in research: the gene can be expressed in other living organisms, making it possible to create gene fusions and hence to visualize the localization of specific gene products inside living cells. GFP comprises 238 amino acids arranged in a helical basket motif, within which three amino acids form an annular structure that mediates its fluorescent properties. *See also enhanced green fluorescent protein.*

GRF *abbr. (sometimes) for* growth hormone releasing factor (i.e. GHRH).

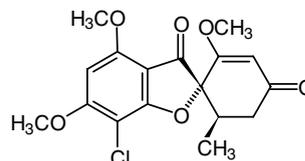

Gri *symbol for* glyceric acid or glycerate.

grid 1 a framework made up of fine wires arranged in two sets at right angles to each other, especially a device for supporting the specimen in an electron microscope. **2** an electrode controlling the current flowing through a thermionic valve.

Grid the basis for the rapidly developing field of grid computing. It enables scalable virtual organizations (VOs), has some parallels with the World Wide Web, but differs in that the members of the VO can not only access data but also run applications on computers in the grid. The Grid has its own **protocols** and **APIs** and has enormous implications for bioinformatics.

Grim a protein of *Drosophila* that functions, like mammalian **Diablo**, in promoting apoptosis. It binds **IAP**, releasing any associated caspase, and thereby is essential for apoptosis.

griseofulvin [2*S*]-*trans*-7-chloro-2',4,6-trimethoxy-6'-methylspiro[benzofuran-2(3*H*),1'-(2)cyclohexene]-3,4'-dione; a chlorine-containing **polyketide** metabolite of *Penicillium griseofulvum* and *P. janczewskii*. It has antifungal properties and is used therapeutically, e.g. for treatment of ringworm. It inhibits spindle formation in mitosis, microtubule function, and possibly nucleic-acid synthesis.

GRK *abbr. for* G-protein coupled receptor kinase; a widely expressed protein kinase that can phosphorylate many G-protein-coupled receptors. There are three isoforms: GRK2 and GRK3 contain an N-terminal RGS domain (*see RGS protein*), a central protein kinase domain, and a C-terminal pleckstrin homology (PH) domain. GRK1 lacks the PH domain.

Grn *symbol for* glycerone.

gRNA *abbr. for* guide RNA; small RNA molecules, 60–80 nucleotides long, that may be involved in editing of RNA by supplying information concerning nucleotide deletion or addition. *See also editosome.*

gro the symbol for any of a group of related genes found in bacteria (especially *Escherichia coli*), mutations in which affect the growth of phages.

Gro *symbol for* glycerol.

groEL symbol for any of a family of bacterial genes encoding **chaperonins**. Eukaryotic homologs are the hsp60 and Cpn60 proteins respectively of mitochondria and chloroplasts. Example of a *groEL* protein from *Escherichia coli*: oligomer of 14 subunits composed of two stacked rings of seven subunits; it has ATPase activity.

groES symbol for any of a family of bacterial genes encoding **cochaperonins** that functions with *groEL*. Eukaryotic homologs are the hsp 10 and Cpn 10 proteins respectively of mitochondria and chloroplasts, that cycle on and off the hsp60 or Cpn60 cylinder in response to its ATPase activity. Example of a *groES* protein product from *Escherichia coli*: seven subunits arranged in a ring. *See chaperonin.*

Grotthus and Draper law a law stating that only those radiations absorbed by a system are effective in producing chemical change in the system.

groundplasm or **cytoplasmic matrix** the sub-electron-microscopic material of the **cytoplasm**, excluding the cell organelles, cell particles,

and other microscopically resolvable structures. It contains the cytoplasmic enzymes and metabolites together with components of the **cytoskeleton**.

ground state the state of lowest energy of any system.

ground substance an alternative name for the **matrix** (def. 2) of connective tissue.

ground tissue a collective term for plant tissue other than the epidermis or peridermis and vascular tissue.

group (*in chemistry*) or (*formerly*) **radical 1** any defined continuously linked collection of atoms within a molecular entity. In organic chemical nomenclature the meaning within this general sense is restricted to any covalently bonded collection of atoms that behaves as a unit in chemical reactions; **functional group**, **substituent group**. **2** any of the columns of chemical elements in the **periodic table**. **3** a **blood group**.

group pK the **pK** of a specific group in a molecule with two or more acid groups. In general the term applies only to a particular ionic form of the molecule, because the **pK** of a group changes when any other group in the molecule changes its ionization state, and thus changes as the substance is titrated. *Compare* **molecular pK**, **titration pK**.

group potential the tendency of a **group** (def. 1) to escape from a molecular entity.

group-transfer potential the Gibbs energy change (free energy change, ΔG) occurring when a **group** (def. 1) is transferred from a donor compound to the nucleophile water, i.e. when the group is removed by hydrolysis of the donor. It reflects the thermodynamic tendency for the group to be transferred.

group-transfer reaction any chemical reaction in which a **group** (def. 1) is transferred from a donor compound to an acceptor compound. Such reactions may be catalysed by a **transferase** enzyme of EC class 2.

group translocation any process in which a substance to be transported across a biological membrane undergoes covalent modification concomitant with crossing the membrane. The best-known example is the group of bacterial phosphotransferases, which catalyse phosphorylation of some mono- and disaccharides, and of sugar alcohols during their import into cells.

growth curve the change, as a function of time, in the number of cells of a growing culture or in some measure of the size of an organism.

growth factor 1 any specific substance that must be present in a culture medium for multiplication of the cultured cells to take place. **2** a specific substance that is a necessary constituent of the diet for the normal growth of a particular animal, or is required in the soil for the normal growth of a particular plant.

growth factor receptor-bound protein 2 *see* **Grb2**.

growth hormone another name for **somatotropin**.

growth hormone inhibitory factor *abbr.*: GHIF or GIF; a former name for **somatostatin**.

growth hormone release-inhibiting hormone *abbr.*: GH-RIH; a former name for **somatostatin**.

growth hormone releasing factor *abbr.*: GHRF or GRF; another name for **GHRH**.

growth hormone releasing hormone *see* **GHRH**.

growth hormone-releasing peptide *abbr.*: GHRp; a synthetic hexapeptide that stimulates release of somatotropin by binding to a highly conserved G-protein-coupled receptor in the pituitary for which the physiological ligand is unidentified.

Grp94 an alternative term for **gp96**.

GRP *see* **Grb2**.

GRP 75 *see* **mortalin**.

GRS (*in clinical chemistry*) *abbr.* for β -glucuronidase.

Grunstein-Hogness procedure an alternative name for **colony hybridization**.

GSH *abbr.* for **glutathione**.

GSK-3 *abbr.* for **glycogen synthase kinase-3**.

GSS *abbr.* for genome survey sequence.

GSSG *abbr.* for oxidized glutathione (*see* **glutathione**).

GST *abbr.* for **glutathione S-transferase** (*see* **glutathione transferase**).

GST fusion protein any protein that has been genetically engineered to have glutathione-S-transferase (GST) fused at its N-terminal end.

A range of **pGEX vectors** are designed to facilitate such expression in *E. coli*. The fusion protein can be purified by affinity chromatography on columns of immobilized glutathione.

GT *abbr.* for **glycosyltransferase**.

GT-AG rule a rule stating that in RNA there is a requirement for a **GT** at the 5' side of a splice junction and an **AG** at the 3' side.

GTBP *abbr.* for **G/T binding protein**; a human homologue (1292 amino acids) of *E. coli* **MutS** protein that is essential for DNA G/T mismatch recognition and binding. It forms a heterodimer with **MutS** homologue 2 (**hMSH2**). Mutations in **GTBP** are present in many hereditary, and some sporadic, colorectal cancers.

GTD (*in clinical chemistry*) *abbr.* for **glutathione reductase**.

G-tetrad an alternative name for **G-quartet**.

GTF *abbr.* for **glucose-tolerance factor**.

GTP *abbr.* for **guanosine triphosphate**.

GTPase any enzymic activity that hydrolyses **GTP** to **GDP** and orthophosphate. It is associated with **G-proteins**, **EF-Ts**, and **HIV protein**.

GTP-binding protein any of various proteins that bind **GTP** as a regulatory molecule; this binding is frequently associated with a **GTPase** activity. **GTP-binding** proteins include elongation and initiation factors (e.g., **EF-Tu**), **G proteins**, **G25K GTP-binding protein**, **Ras proteins**, and yeast **CDC42** (*see* **CDC markers**). Binding of **GTP** normally activates the protein, an effect that is reversed by hydrolysis of the **GTP** to **GDP**.

GTP[S] or **GTP γ S** *abbr.* for **guanosine 5'- γ -thiotriphosphate**.

GTR1 a representative 12-transmembrane domain transport protein that effects the facilitated diffusion of glucose in certain mammalian tissues.

GTT *abbr.* for **glucose tolerance test**.

Gu *symbol* for **guanidine**.

Gua *symbol* for a residue of the purine base **guanine** (alternative to **G**).

GUA a codon in mRNA for **L-valine**.

guanidine *symbol*: **Gu**; the strongly basic substance, iminouric acid; aminomethanamide; $(\text{H}_2\text{N})_2\text{C}=\text{NH}$.

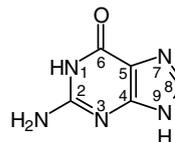

guanidinium the cation, $[\text{C}(\text{NH}_2)_3]^+$, derived from **guanidine** by uptake of a hydron.

guanidinium isothiocyanate a powerful **chaotrope** used as a protein denaturant in the extraction of RNA from biological materials. Both the **guanidinium** cation and the **isothiocyanate** anion are strong chaotropic agents.

guanidino the amidinoimino group, $-\text{HN}-\text{C}(\text{=NH})-\text{NH}_2$, derived from **guanidine**.

guanidinoacetate *N*-methyltransferase EC 2.1.1.2; an enzyme of the pathway for *de novo* synthesis of **creatine**, by reaction of *S*-adenosyl-L-methionine with **guanidinoacetate** releasing *S*-adenosyl-L-homocysteine.

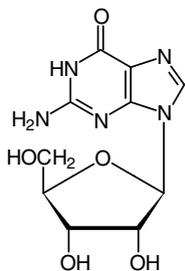

guanine *symbol*: **G** or **Gua**; 2-amino-6-hydroxypurine; 2-amino-1,7-dihydro-6H-purin-6-one; a purine that is one of the five main bases found in nucleic acids and a component of a number of phosphorylated **guanosine** derivatives whose metabolic or regulatory functions are important.

guanine nucleotide binding protein *see* **GTP-binding protein**.

guanine nucleotide releasing protein *abbr.*: **GNRp**; or **guanine nucleotide releasing factor**, *abbr.*: **GRF**; a protein that binds to a **Ras** protein (*see* **Ras family of proteins**) or **Ras-related GTP-binding protein**, and activates it by stimulating it to release its bound **GDP** and to bind **GTP** in its place. The C-terminal 310 amino acids share similarity with **Cdc25** (*see* **cdc gene**) and **Sos**, the product of **sos**.

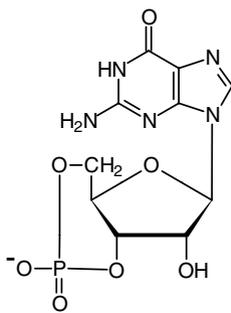

guanosine *symbol*: **G** or **Guo**; **guanine** riboside; β -D-ribofuranosylguanine; a **nucleoside** with a wide species distribution.

guanosine

guanosine 2',3'-(cyclic)phosphate *see* guanosine phosphate.

guanosine 3',5'-(cyclic)phosphate or **guanosine 3',5'-cyclophosphate** *see* guanosine 3',5'-phosphate.

guanosine 5'-diphosphate *symbol:* Guo5'PP or ppG; *the recommended name for* guanosine diphosphate (*abbr.:* GDP), 5'-diphosphoguanosine, 5'-guanylyl phosphate, guanosine 5'-(trihydrogen diphosphate), a universally distributed nucleotide that occurs in both the free state and as a component of **guanosinediphosphoguanosine**. It is a metabolic precursor of guanosine 5'-triphosphate, GTP, and is a substrate, a product, or a regulatory agent in many metabolic systems.

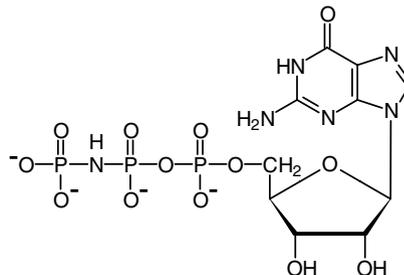

guanosine 3'-diphosphate 5'-diphosphate *symbol:* ppGpp; *see* *relA*, *spoT*.

guanosinediphosphomannose or **guanosine(5')diphospho(1)- α -D-mannose** *symbol:* GuoPPMan; *the alternative recommended names for* guanosine diphosphate mannose (*abbr.:* GDPM or GDP-mannose); guanosine 5'-(α -D-mannopyranosyl diphosphate); α -D-mannopyranosyl 5'-guanylyl phosphate; the most important **guanosinediphosphosugar**. It is synthesized from α -D-mannose 1-phosphate and guanosine 5'-triphosphate by the action of **mannose-1-phosphate guanylyltransferase** (EC 2.7.7.13). It is an intermediate in the synthesis of mannose-containing homo- and heteroglycans in plants. In animal cells GDPmannose is an intermediate in the incorporation of residues of both mannose and fucose into *N*-linked oligosaccharides of glycoproteins, its conversion to GDP-L-fucose having first taken place in the case of fucose.

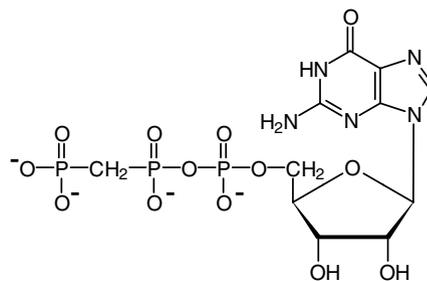

guanosinediphosphosugar or **guanosine diphosphate sugar** *abbr.* GDPsugar; any of several **nucleosidediphosphoguanosine**s in which the distal phosphoric residue of guanosine 5'-diphosphate is in glycosidic linkage with a monosaccharide (or a derivative of a monosaccharide). Included are GDP-L-fucose, GDP-D-glucose, GDP-L-guluronic acid, GDP-D-mannose (*see* **guanosinediphosphomannose**), and GDP-D-mannuronic acid.

guanosine 5'-[β , γ -imido]triphosphate *symbol:* Guo-PP[NH]P or p[NH]ppG; *the recommended name for* β , γ -imidoguanosine 5'-triphosphate (*abbr.:* GTP[β , γ -NH]), 5'-guanylyl imidodiphosphate (*abbr.:* GMP-PNP), 5'-guanylyl iminodiphosphonate, guanosine

(5' \rightarrow O³)-1,2- μ -imidotriphosphate, a synthetic nonhydrolysable analogue of guanosine triphosphate, GTP, in which the oxy group between the latter's intermediate and terminal phosphorus atoms is replaced by an imido group. It stimulates G-proteins and systems activated thereby.

guanosine 5'-[β , γ -methylene]triphosphate *symbol:* GuoPP-[CH₂]P or p[CH₂]ppG; *the recommended name for* β , γ -methylene-guanosine 5'-triphosphate, (*abbr.:* GTP[β , γ -CH₂]), 5'-guanylyl methylenediphosphonate (*abbr.:* GMP-PCP), guanosine (5' \rightarrow O³)-1,2- μ -methylenetriphosphate, a synthetic nonhydrolysable analogue of guanosine 5'-triphosphate, GTP, in which the oxy group between the latter's intermediate and terminal phosphorus atoms is replaced by a methylene group. It is an effective activator of ADP-ribosylation factor but not of G_s (*see* **G-protein**).

guanosine monophosphate *abbr.:* GMP; *an alternative name for* any guanosine phosphate, but in particular for **guanosine 5'-phosphate**, especially when its distinction from guanosine (5'-)diphosphate and guanosine (5'-)triphosphate requires emphasis.

guanosine phosphate *symbol:* GuoP; guanosine monophosphate (*abbr.:* GMP); any phosphoric monoester or diester of guanosine. There are three monoesters – guanosine 2'-phosphate, guanosine 3'-phosphate, and **guanosine 5'-phosphate** – and two diesters – guanosine 2',3'-phosphate and **guanosine 3',5'-phosphate** – although guanosine 5'-phosphate, guanylic acid is the ester commonly denoted (the locant being omitted if no ambiguity may arise). Guanosine 2',3'-phosphate (*symbol:* Guo-2',3'-P), also named guanosine 2',3'-(cyclic)phosphate or cyclic guanosine 2',3'-monophosphate (*abbr.:* 2',3'-cyclic GMP), is formed as an intermediate during the alkaline hydrolysis of ribonucleic acid. This diester then readily hydrolyses to a mixture of the two monoesters guanosine 2'-phosphate (*symbol:* Guo2'P), also named guanosine 2'-monophosphate (*abbr.:* 2'GMP) or 2'-guanylic acid or guanylic acid a, and guanosine 3'-phosphate (*symbol:* Guo3'P), also named guanosine 3'-monophosphate (*abbr.:* 3'GMP) or 3'-guanylic acid or guanylic acid b.

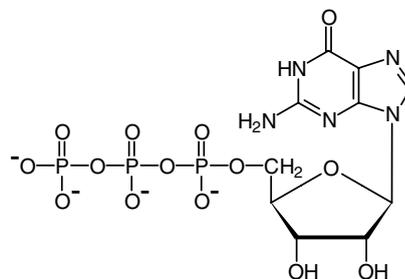

guanosine 2'-phosphate *see* **guanosine phosphate**.

guanosine 2',3'-phosphate *see* **guanosine phosphate**.

guanosine 3'-phosphate *see* **guanosine phosphate**.

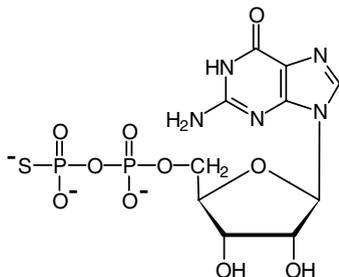

guanosine 3',5'-phosphate *symbol:* Guo-3',5'-P; *the recommended name for* cyclic guanosine 3',5'-monophosphate (*abbr.:* 3',5'-cyclic GMP or cyclic GMP or cGMP), guanosine 3',5'-cyclophosphate, guanosine 3',5'-(cyclic) phosphate, a monophosphoric diester of

guanosine found in practically all mammalian tissues. It is a cyclic nucleotide similar in structure and the regulation of its metabolism to **adenosine 3',5'-phosphate**, cyclic AMP, but the levels in tissues are commonly less than 5 percent of those of cyclic AMP. Also like cyclic AMP, it acts as a **second messenger** in many systems, and it activates a number of distinct cyclic-GMP-dependent protein kinases that share some of their properties with their cyclic AMP counterparts; in some instances it antagonizes the action of cyclic AMP. Cyclic GMP is produced by the action of **guanylate cyclase** on guanosine 5'-triphosphate, GTP, and it mediates signal transduction for systems that activate this enzyme.

guanosine 5'-phosphate or **5'-guanylic acid** or **5'-phosphoguanosine** or **5'-O-phosphoguanosine** *symbol*: Guo5'P; *alternative recommended names for guanosine 5'-monophosphate (abbr.: 5'GMP)*, guanosine 5'-(dihydrogen phosphate), guanine (mono)ribonucleotide. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation.) It is biosynthesized from inosine 5'-phosphate, 5'-inosinic acid, via xanthosine 5'-phosphate and also from free guanine by the **salvage pathway**.

guanosine 5'-β-thiodiphosphate *symbol*: Guo5'PP[S] or [S]ppG; *the recommended name for guanosine 5'-[β-thio]diphosphate (abbr.: GDPβS)*, guanosine 5'-(2-thiodiphosphate) (*abbr.*: GDP[S]), guanosine (5'→O²)-1-thiodiphosphate, a synthetic nonhydrolysable analogue of guanosine 5'-diphosphate, GDP, in which an oxygen atom of its terminal phosphoric residue is replaced by a sulfur atom. It is a competitive inhibitor of the activation of G-proteins by guanosine 5'-triphosphate and of the stimulation of adenylate cyclase by guanosine 5'-triphosphate and fluoride.

guanosine 5'-γ-thiotriphosphate *symbol*: GuoPPP[S] or [S]pppG; *the recommended name for guanosine 5'-[γ-thio] triphosphate (abbr.: GTP-γ-S)*, guanosine 5'-(3-thiophosphate) (*abbr.*: GTP[S]), guanosine (5'→O³)-1-thiotriphosphate, a synthetic nonhydrolysable analogue of guanosine 5'-triphosphate, GTP, in which an oxygen atom of its terminal phosphoric residue is replaced by a sulfur atom. It is used in membrane studies to stimulate G-proteins and in studies of DNA synthesis.

guanosinetriphosphatase a GTP-hydrolyzing enzyme belonging to group EC 3.6.1 and involved in transduction of information (EC 3.6.1.46, EC 3.6.1.49), protein synthesis (EC 3.6.1.48), and movement of intracellular particles (EC 3.6.1.47, EC 3.6.1.50, EC 3.6.1.51).

guanosine 5'-triphosphate *symbol*: Guo5'PPP or pppG; *the recommended name for guanosine triphosphate (abbr.: GTP)*, 5'-triphosphoguanosine, 5'-guanylyl diphosphate, guanosine 5'-(tetrahydrogen triphosphate), an important coenzyme and enzyme regulator present in all cells. It is formed from guanosine 5'-diphosphate by substrate-level phosphorylation or by transfer of the terminal phosphoric residue from **adenosine 5'-triphosphate** through the action of nucleoside-diphosphate kinase (EC 2.7.4.6). Reactions in which GTP participates are often driven in the direction leading to hydrolysis, the free energy change then being utilized for energy-requiring purposes, e.g. microtubule assembly or protein biosynthesis. GTP also participates in various synthetic reactions by the transfer of a phosphoric residue to other metabolites, e.g. to oxaloacetate to form phosphoenolpyruvate in gluconeogenesis.

guanosine triphosphate cyclohydrolase EC 3.5.4.16; the first enzyme in the biosynthesis of tetrahydrobiopterin. It catalyses the reaction:

The enzyme, whose subunits each contain 250 amino acids and form a stack of two pentamers, occurs mainly in monoaminergic neurons, adrenal medulla, and liver. Deficiency is rare and results from numerous mutations associated with dopa-sensitive dystonia. *See biopterin*.

guanosyl any chemical group formed by the loss of a 2', a 3', or a 5'-hydroxyl group from the ribose moiety of guanosine. *Compare guanylyl*.

guanyl *misnomer for 1 guanylyl. 2 guanylate*.

guanylate **1** the mono- or the di-anion of **guanylic acid**. **2** any mixture of guanylic acid and its anions. **3** any salt or ester of guanylic acid.

guanylate cyclase EC 4.6.1.2; *systematic name*: GTP pyrophosphate-lyase (cyclizing); *other names*: guanylyl cyclase (not recommended but often used); guanyl cyclase (incorrect). An enzyme that catalyses the elimination of pyrophosphate from guanosine 5'-triphosphate, GTP, by formation of guanosine 3',5'-phosphate, cyclic GMP. There are two types: (1) a heterodimer of α and β chains; and (2) a membrane-bound form, typical of some receptors. A retina-specific receptor guanylate cyclase (retGC-1) is present in the outer segment of cone cells and is activated by retina-specific activator proteins. Many mutations in the gene for retGC-1 at 17p13.1 result in Leber's congenital amaurosis (a form of blindness). *See GCAP*.

guanyl cyclase *incorrect name for guanylate cyclase*.

guanylic acid *the trivial name for any phosphoric monoester of guanosine*. The position of the phosphoric residue on the ribose moiety of a given ester may be specified by a prefixed locant. *see guanosine phosphate*. However, 5'-guanylic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-Guanylic acid is also an alternative recommended name for **guanosine 5'-phosphate**.

guanylin a pentadecapeptide paracrine hormone that contains four disulfide bonds and represents the C-terminal segment of preproguanylin (115 amino acids). It is secreted by enterochromaffin cells along the intestinal tract, secretory cells in bronchioles, and probably the kidney. Its receptor is a membrane receptor guanylate cyclase that also binds the heat-stable enterotoxin of several Gram-negative bacteria. It acts to increase secretion of NaCl.

guanylyl the guanosine[mono]phospho group; the acyl group derived from **guanylic acid**.

guanylylation the process of introducing guanylyl groups into a substance.

guanylyl cyclase *see guanylate cyclase*.

guaran a mucilaginous **galactomannan** of ≈ 220 kDa that serves as a storage polysaccharide in the seeds of guar and is the prime constituent of **guar gum**. It consists of long chains of (1 \rightarrow 4)-linked β -D-mannopyranose residues, to every alternate one of which a single α -D-galactopyranose residue is attached in (1 \rightarrow 6)-linkage.

guard cell either of a pair of crescent-shaped cells that surround a **stoma** in plants.

guard column a small column fitted in front of the main column as a device to prolong the life of columns in high-performance liquid chromatography by removing from the sample any particulate matter, aggressive agents, or components that bind irreversibly to the column packing.

guar gum a greyish-white powder consisting predominantly of the polysaccharide **guaran** and obtained by grinding the endosperm of the seeds of guar, an Indian leguminous plant, *Cyamopsis tetragonoloba* (*psoralioides*), also called cluster bean. It hydrates and disperses readily in cold water to give colloidal solutions of very high viscosity that are stable over a very wide pH range and have very good suspending and lubricating properties. It is used for sizing paper and textiles, and as a stabilizing, suspending, and thickening agent in the food and pharmaceutical industries, etc. It has also been suggested as a nonabsorbable dietary additive to improve glycemic control in diabetes mellitus, possibly by slowing the uptake of ingested absorbable carbohydrate.

GUC a codon in mRNA for L-valine.

guessmer an oligonucleotide probe assembled on the basis of partial protein sequence information coupled with intelligent guesswork guided by knowledge of codon usage. Such a probe is used to screen a cDNA library for the corresponding gene.

GUG a codon in mRNA for L-valine.

Guggenheim plot a procedure that makes it possible to obtain rate constants for first-order reactions when neither the initial nor the final reactant concentrations are known. Measurements of the concentration of the reactant (or of some physical quantity that measures it), $c_1, c_2, c_3, \dots, c_n$, are made at times $t_1, t_2, t_3, \dots, t_n$ and also at times $(t_1 + \delta t), (t_2 + \delta t), (t_3 + \delta t), \dots, (t_n + \delta t)$, when the concentrations of the reactant are $c_1', c_2', c_3', \dots, c_n'$, where δt is a constant time difference, then

$$\ln(c_i - c_i') = \ln(c_0 - c_\infty)(1 - e^{-k\delta t}) - kt,$$

or

$$\ln(c_i - c_i') = \text{a constant} - kt_i,$$

hence a plot of $\ln(c_i - c_i')$ versus t_i has a slope of $-k$. [After Edward Armand Guggenheim (1901–70), British physical chemist.]

guide RNA *see* **gRNA**.

guinea pig any of several species of wild or domesticated hystriomorph rodents, or cavies, in the genus *Cavia*, especially *Cavia porcellus*, which is widely used in biomedical research and testing.

Guinier plot a method of plotting the results of small-angle X-ray scattering to obtain the radius of gyration of a molecule, r_G , in the absence of information about the relative molecular mass of the component in question. It can be shown that

$$\ln(I_\theta/I_0) = -(4\pi r_G \sin\theta / \lambda)^2/3,$$

where I_θ and I_0 are the intensities of the scattered radiation at angles θ and 0 respectively, and λ is the wavelength of the radiation; hence a plot of $\ln(I_\theta/I_0)$ versus $-(4\pi \sin\theta / \lambda)^2/3$ will yield r_G .

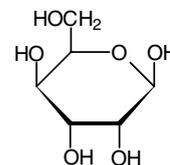

Gul *symbol* for a residue (or sometimes a molecule) of the aldohexose gulose.

GulA *symbol* for a residue (or sometimes a molecule) of the uronic acid gularonic acid.

gulo- *prefix (in chemical nomenclature)* indicating a particular configuration of a set of (usually) four contiguous >CHOH groups, as in the acyclic form of D- or L-gulose. *See* **monosaccharide**.

L-gulonolactone oxidase EC 1.1.3.8; *other name*: L-gulonolactone oxidase; a flavoprotein enzyme that catalyses the oxidation by dioxygen of L-gulonolactone to L-xulo-hexulonolactone (I) and H₂O₂. I isomerizes spontaneously to L-ascorbate. The flavin is FAD. The enzyme is essential for the formation of ascorbate, and a deficiency of the enzyme, as in humans, results in dependency on a dietary supply of ascorbate (*see* **ascorbic acid**). Example from rat: GGLO_RAT, 439 amino acids (50.42 kDa).

gulose *symbol*: Gul; *the trivial name* for the aldohexose gulo-hexose; a stereoisomer of glucose in which the configurations at both C-3 and C-4 are inverted. There are two enantiomers. (Illustrated opposite.)

gulose (β -D-pyranose form)

gularonic acid *symbol*: GulA; *the uronic acid* resulting from the oxidation of the hydroxymethylene group at C-6 of gulose to a carboxyl group. L-Gularonic acid is a component of **alginic acid**.

gum any of numerous water-soluble or water-dispersible heteroglycans, frequently containing uronic acids, that are produced as exudates from certain plants, especially trees, following physical injury. Gums are tacky, slimy substances that harden when dry. *See also* **gum arabic**, **gum ghatti**.

gum arabic a **gum** exuded from trees of the genus *Acacia*. Structurally it is a heteroglycan containing D-galactose, L-arabinose, L-rhamnose, and D-guluronic acid. It is used in industry, e.g. in the manufacture of thickening agents, emulsifiers, inks, and pills. It is also used in glues and pastes.

gum ghatti a **gum** from the tree *Anogeissus latifolia*. It has a complex structure and contains as major components D-mannose, D-galactose, and L-arabinose, the latter in both furanose and pyranose arrangement. Small amounts of D-xylose and D-glucuronic acid are also present.

GUN4 a nuclear-encoded protein (266 amino acids) of *Arabidopsis thaliana* chloroplasts that controls synthesis of Mg-protoporphyrin IX through its action on Mg-chelatase. GUN4 binds the product and the substrate of Mg-chelatase and represses many nuclear genes that control plastid differentiation. The name derives from the chlorophyll-deficient mutant *gun4*. A similar protein is present in other plants.

Gunn rat any member of a mutant strain of Wistar rats with hereditary hyperbilirubinemia. The defect affects the rate of glucuronidation of a number of substrates, but not equally. [After C. H. Gunn.]

Güntelberg-Müller charging process a method of calculating the electrical energy of an ion. According to the process, only the ion under consideration is supposed to receive a charge; the surrounding ions are assumed to be already charged, and the only change that they undergo during the process is a gradual redistribution as the central ion receives its charge.

Guo *symbol* for a residue of the ribonucleoside guanosine (alternative to G).

GuoP *symbol* for guanosine phosphate.

Guo2'P *symbol* for guanosine 2'-phosphate; *see* **guanosine phosphate**.

guo-2',3'-P *symbol* for guanosine 2',3'-phosphate; *see* **guanosine phosphate**.

Guo3'P *symbol* for guanosine 3'-phosphate; *see* **guanosine phosphate**.

Guo-3',5'-P *symbol* for guanosine 3',5'-phosphate.

Guo5'P *symbol* for guanosine 5'-phosphate.

Guo5'PP *symbol* for guanosine diphosphate (alternative to ppG).

GuoPP(CH₂)P *symbol* for guanosine 5'-[β , γ -methylene] triphosphate (alternative to p[CH₂]ppG).

GuoPPMan *symbol* for guanosediphosphomannose.

GuoPP(NH)P *symbol* for guanosine 5'-[β , γ -imido]triphosphate (alternative to p[NH]ppG).

Guo5'PPP *symbol* for guanosine 5'-triphosphate (alternative to pppG).

Guo5'PPP[S] *symbol* for guanosine 5'- γ -thiotriphosphate.

Guo5'PP[S] *symbol* for guanosine 5'- β -thiodiphosphate.

Gurken a transforming growth factor α -related protein produced in the dorsal region of *Drosophila* embryos, where it is involved in dorsoventral specification. It binds a membrane tyrosine kinase receptor that activates Ras.

gustducin a taste-cell-specific G protein α subunit closely related to the transducins, and comprising 354 amino acids.

gut a term variously used to describe the whole of the alimentary canal or only the intestine, i.e. the part from the stomach to the anus.

gut glucagon (*sometimes*) an alternative term for **enteroglucagon**.

gut hormone a general, inaccurate, but widely used term for all the various regulatory peptides of the gut. They are neither confined to the gut, nor are they exclusively hormones.

Guthrie test a microbiological test in which a strain of *Bacillus subtilis* that requires phenylalanine for growth is used to test for excessive levels of plasma phenylalanine in conditions such as **phenylketonuria**. [After R. Guthrie (1916–).]

gutta-percha a *trans*-1,4-polyisoprene derived by coagulation of the latex of various Malayan trees of the genus *Palaquium*. It has a lower molecular mass than rubber and is thermoplastic.

GUU a codon in mRNA for L-valine.

g-value or **g-factor** a factor that specifies the position at which the absorption of a paramagnetic species occurs in an EPR spectrum. For a free electron in a vacuum, *g* has the value 2.002 319 304 4.... In a paramagnetic molecule, the energy difference between the two states is affected by interaction of the unpaired electron spin with electron orbitals. For the purposes of EPR spectroscopy, these interactions are taken into account by allowing the *g*-value to be a

spectroscopic variable. For a field B_0 and frequency ν , resonance occurs when $h\nu = g\mu_B B_0$, where h is the Planck constant and μ_B is the Bohr magneton.

G value (in nuclear chemistry) the number of specified chemical events in an irradiated substance produced per 100 eV of energy absorbed from ionizing radiation.

Gy symbol for gray.

gynaminic acid formerly, a name for a constituent of human milk, now known to be identical with **sialic acid**.

gynogamone see **gamone**.

gyrase see type II DNA topoisomerase.

gyrate atrophy of choroid and retina see OAT.

gyrin any of several membrane proteins, including synaptogyrins 1 to 4, that occur as components of transport vesicles and neurotransmitter vesicles. They contain four transmembrane segments, have intracellular N- and C-termini, and resemble the physins in both their architecture and function. **Synaptogyrin 2** (also called cel-lugyrin) is also present in vesicles that contain glucose transporter 4 (GLUT4). Homologues occur in *Drosophila* and *Caenorhabditis*.

gyromagnetic ratio or **magnetogyric ratio** symbol: γ ; the ratio of the magnetic moment, μ , of a given atomic particle to its angular momentum, L ; i.e. $\gamma = \mu/L$. See also **proton magnetogyric ratio**.

Hh

h symbol for 1 hecto+ (SI prefix denoting 10^2 times). 2 hour (supercedes hr.).

h symbol for 1 Planck constant. 2 Hill coefficient (alternative to n_H). 3 height.

h+ or (not recommended) **H+** prefix to abbreviations for peptide hormone (names) denoting human, i.e. of (or as if of) human origin; e.g. hGH (for human growth hormone).

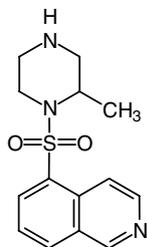

H symbol for 1 hydrogen; see also **protium**, **deuterium**, **tritium**. 2 a residue of the α -amino acid **histidine** (alternative to His). 3 a residue of an incompletely specified base in a nucleic-acid sequence that may be adenine, cytosine, or either thymine (in DNA) or uracil (in RNA).

4 henry. 5 histone. 6 histamine (see **histamine receptor**).

H+ see **h+**.

H1 a DNA-binding protein from *Escherichia coli* belonging to the **HNS** family of proteins.

H7 1-(5-isoquinolinylnsulfonyl)-2-methylpiperazine; an inhibitor of protein kinase C ($K_i = 6.0 \mu\text{M}$), protein kinase A ($K_i = 3.0 \mu\text{M}$), and cyclic GMP-dependent protein kinase ($K_i = 5.8 \mu\text{M}$).

H₂ symbol for 1 dihydrogen. 2 the prefix **dihydro+** in a trivial chemical name, e.g. H₂folate for dihydrofolate.

H₄ symbol for the prefix **tetrahydro+** in a trivial chemical name, e.g. H₄folate for tetrahydrofolate.

H symbol for 1 fluence (alternative to *F*). 2 enthalpy. 3 magnetic field strength (light italic in nonvector equations; bold italic in vector equations).

-H conformational descriptor designating the half-chair conformation of a six-membered ring form of a monosaccharide or monosaccharide derivative. Locants of ring atoms that lie on the side of the structure's reference plane from which the numbering appears clockwise are indicated by left superscripts and those that lie on the other side of the reference plane by right subscripts; e.g. methyl 2,3-anhydro-5-thio- β -L-lyxopyranoside-5-*H*_s. See also **conformation**.

H- or (sometimes) **H** (in chemical nomenclature) symbol for indicated hydrogen (at the position specified by a prefixed locant).

Habc domain abbr. for helix a, b, and c domain; a protein sequence in the N-terminal region of syntaxins that forms a triple alpha-helix bundle that folds back on the SNARE domain (which consists of heptads) and prevents it from forming complexes with other SNAREs.

Haber-Weiss reaction the iron-catalysed reaction of a superoxide anion with hydrogen peroxide to form oxygen, a hydroxyl radical, and a hydroxyl ion. It is thought to proceed as follows:

[After Fritz Haber (1868–1934), German chemist, and Joseph Weiss.]

HAc abbr. for acetic acid.

HACBP see **calreticulin**.

HaeII a type 2 **restriction endonuclease**; recognition sequence: [AG]GCGC↑[TC].

HaeIII a type 2 **restriction endonuclease**; recognition sequence: GG↑CC. The *M.HaeIII* modification site is C3.

haem a variant spelling (esp. Brit.) of **heme**.

haema+ or (before a vowel) **haem+** variant spellings (esp. Brit.) of **hema+**.

haemadin a 57-amino-acid anticoagulant peptide from the Indian leech, *Haemadipsa sylvestris*. It is a slow, tight-binding inhibitor of thrombin, but does not inhibit trypsin, chymotrypsin, factor Xa, or plasmin.

haemato+ or (before a vowel) **haemat+** variant spellings (esp. Brit.) of **hemato+**.

haemo+ a variant spelling (esp. Brit.) of **hemo+**.

haemoglobin a variant spelling (esp. Brit.) of **hemoglobin**.

Hageman factor an alternative name for factor XII; see **blood coagulation**.

hairpin any part of a linear molecular structure, e.g. of a polynucleotide strand or a prostaglandin, in which two adjacent segments of the molecule are folded back one on the other and held in that conformation by secondary molecular forces such as hydrogen bonds or van der Waals interactions. **Hairpin DNA** (or foldback DNA or loopback DNA) contains **inverted repeats**; when denatured it renatures extremely rapidly by intrachain base-pairing between complementary sequences of the inverted repeat. Similar structures occur in large RNA molecules. The hairpin conformation of a prostaglandin molecule is thought to be necessary for expression of its hormonal activity; in this conformation the α and κ chains of each molecule are extended, parallel to one another, at van der Waals contact distance for their full lengths. See also **ribozyme**, **beta bend**.

hairy a pair-rule gene of *Drosophila*.

Hakai a protein belonging to the E3 ubiquitin ligase family that specifically binds to phosphotyrosyl residues on E-cadherin, targeting it for ubiquitination and endocytosis. [Japanese for 'destruction'.]

Haldane coefficient the difference, per bound dioxygen molecule, in the number of hydrons bound by oxy- and deoxyhemoglobin, at constant pH. [After John Scott Haldane (1860–1936), British physiologist.]

Haldane effect the observation that oxygenated blood absorbs less carbon dioxide than deoxygenated blood. It is the reciprocal of the **Bohr effect**.

Haldane gas-analysis apparatus an apparatus once used for the estimation of the carbon dioxide and dioxygen contents of a gas sample.

Haldane relation a relation for reversible enzyme reactions. In the single-substrate, essentially reversible reaction:

the overall equilibrium constant,

$$K = C_P/C_S = k_1k_2k_3/k_{-1}k_{-2}k_{-3},$$

where C_S and C_P are the concentrations of substrate, S, and product, P, respectively. It can further be shown that

$$K = V_S K_{mP} / V_P K_{mS},$$

where V_S and V_P are the maximum velocities of the reactions $S \rightarrow P$ in the absence of P and of $P \rightarrow S$ in the absence of S, and K_{mS} and K_{mP} are the respective Michaelis constants for these reactions. [After John Burdon Sanderson Haldane (1892–1964), British biochemist, physiologist, and geneticist.]

half-boat conformation either of the **conformations** of a nonplanar monounsaturated six-membered ring compound when the two ring atoms not directly bound to the doubly bonded atoms lie on the same side of the plane containing the other four (adjacent) atoms.

half-cell one half of an **electric cell**, consisting of one reversible electrode inserted into a solution. Electrical connection between this so-

lution and that in another half-cell is required to complete the electric circuit.

half-chair conformation 1 either of the conformations of a nonplanar monounsaturated six-membered ring compound when the two ring atoms not directly bound to the doubly bonded atoms lie on opposite sides of the plane containing the other four (adjacent) atoms. **2** any conformation of the six-membered ring form of a monosaccharide or monosaccharide derivative when four adjacent ring atoms are coplanar and the other two lie on opposite sides of the plane. The conformational descriptor *-H* may be added to the name of such compounds.

half-cystine or **hemicycstine** *symbol*: C_{ys}^1 or C_{ys}^2 ; the group formally derived by removal of a hydrogen atom from the thiol group on the side chain of cysteine (or of a cysteine residue), or by homolysis of the dithio linkage of cystine (or of a cystine residue). It is used to describe or depict the content or linear sequence of amino-acid residues in a polypeptide when it contains more than two apparent cysteine residues, and the positions of any dithio linkages between them are not known.

half-cystyl or **hemicycstl** the acyl group, $-S-CH_2-CH(NH_2)-CO-$, derived from the **half-cystine** group. *Compare* **cysteinyl**.

half-ester any monoester of a dibasic acid.

half-life 1 *symbol*: $t_{1/2}$ or $T_{1/2}$; the time for one half of the atoms of an amount of radionuclide to undergo radioactive decay. **2** a similar measure of the stability (i.e. rate of decay) of an excited atom or molecule, a radical, an unstable elementary particle, etc. **3** the time for one half of the amount of an administered substance to be metabolized or excreted. If the substance is radioactive, the time required for one half of the dose to be eliminated biochemically or physiologically is termed the **biological half-life** and that required for one half to disappear by radioactive decay as well as by the elimination is the **effective half-life**. **4** or (*sometimes*) **half-time** *symbol*: $t_{1/2}$; the time required for the concentration of a reactant in a chemical reaction to reach a value that is the arithmetic mean of its initial and final (equilibrium) values. **5** the time for one half of the number of cells in a tissue or organ to be replaced by new cells.

half-of-the-sites reactivity or **half-site reactivity** a phenomenon shown by many enzymes that exhibit **negative cooperativity**, in which the maximal stoichiometric yield of either an enzyme–substrate intermediate or a product in a single turnover amounts to only half the number of apparently equivalent active sites. This may be caused by the binding of substrate to one site of a dimeric enzyme, e.g., inducing a conformational change in the enzyme so as to abolish completely the binding affinity of the other site.

half-reaction either of the two coupled chemical changes that together constitute an oxidation–reduction reaction. In one half-reaction there is a gain of electrons and in the other half-reaction a corresponding loss of electrons.

half-shotgun coverage *see* **depth of coverage**.

half-site reactivity *an alternative name for* **half-of-the-sites reactivity**.

half-thickness the thickness of a piece of a specified material that will reduce the intensity of a beam of transmitted electromagnetic radiation to one half that of the incident beam.

half-time *an alternative name for* **half-life** (def. 4) for a first-order process.

half-time of exchange the time taken for one half of the exchangeable atoms (or molecules) to be exchanged in a reaction involving such an exchange.

half-transporter a member of the **ABC transporter** superfamily usually found in peroxisomal or in microbial membranes. It contains a membrane-spanning region (with six transmembrane segments) and a nucleotide-binding domain.

half-wave potential the electrical potential at the mid-point of the current–voltage curve in **polarography**.

halide or **halogenide 1** an anion of any halogen. **2** a salt of any halogen acid (halogen hydride). **3** any compound containing halogen atoms in organic linkage.

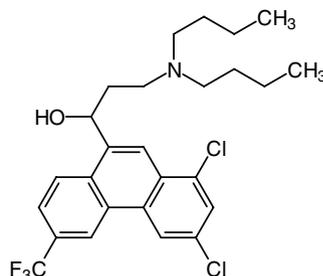

Hallervorden–Spatz syndrome an early-onset neurodegenerative syndrome of parkinsonism, dystonia, and iron accumulation in the brain. It is caused by deficiency of **pantothenate kinase**. [After Julius Hallervorden (1882–1965) and Hugo Spatz (1888–1969), German neurologists.]

hallucinogen any drug or other substance that causes hallucinations. —**hallucinogenic** *adj.*

halo+ or (*sometimes before a vowel*) **hal+** *comb. form 1* relating to or containing a halogen. **2** relating to the sea or salt.

halochromism the phenomenon or property of the formation of strongly coloured compounds on the addition of strong acids or certain metallic salts to colourless or faintly coloured substances.

halofantrine 1,3-dichloro- α -[2-(dibutylamino)-ethyl]-6-(trifluoromethyl)-9-phenanthrenemethanol; a derivative of 9-phenanthrenemethanol that is effective against chloroquine-resistant malarial infections.

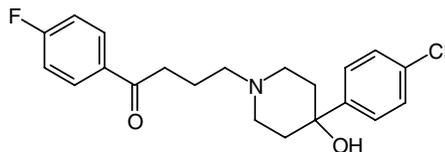

halogen any of the monovalent chemical elements of group 17 of the IUPAC **periodic table**: fluorine, chlorine, bromine, iodine, and astatine.

halogenate to treat or react (a substance) with a halogen; to introduce one or more halo groups into an organic compound. —**halogenation** *n.*

halogenide *an alternative name for* **halide**.

haloperidol 4-[4-(4-chlorophenyl)-4-hydroxy-1-piperidinyl]-1-(4-fluorophenyl)-1-butanone; one of the butyrophenone group of **neuroleptic** drugs.

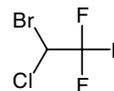

haloperoxidase one of a group of enzymes that halogenate organic substrates using hydrogen peroxide and a halide ion (Cl^- , Br^- , or I^-). Haloperoxidases contain either heme or vanadium.

halophile 1 an organism that grows in or tolerates saline conditions, especially concentrations of sodium chloride equal to or greater than that in sea water. **2** describing such an organism. —**halophilic** *adj.*

halorhodopsina pigment identified in membranes of *Halobacterium halobium*. It is similar to **bacteriorhodopsin** and, upon absorption of a photon, catalyses inward transport of chloride ions.

halothane *the trivial name for* 2-bromo-2-chloro-1,1,1-trifluoroethane, a widely used, volatile, lipid-soluble general inhalational anesthetic agent.

hamamelose 2-C-(hydroxymethyl)-D-ribose; a substance found principally in **tannin** of witch hazel (*Hamamelis virginiana*).

hamartin a protein (1164 amino acids) that is widely expressed, con-

tains a potential transmembrane segment and a predicted coiled-coil domain, and has no homology to any other protein. It may be a tumour suppressor, and forms a mainly cytosolic complex with **tuberin**. Many mutations in the gene at 9q34 produce the autosomal dominant tuberous sclerosis type 1 (TSC1).

Hamburger shift *an alternative name for chloride shift*. [Named after Hartog Jakob Hamburger (1859–1924), Dutch physiologist.]

Hamiltonian operator *symbol: H*; a function used to express the total energy of a system in joules: $H = T + V$, where T is the kinetic energy operator and V the potential energy operator. For a particle of mass m and momentum p ,

$$H = p^2/2m + V.$$

[After William Rowan Hamilton (1805–65), Irish astronomer and mathematician.]

hamlet a protein that acts as a binary genetic switch between single- and multi-dendrite neuron morphology in *Drosophila* embryos. It is predicted to contain 990 amino acids, with six zinc fingers in the N-terminal half and three more towards the C-terminus. It may be a nuclear transcription factor.

hammerhead *see ribozyme*.

Ham's F10 medium, **Ham's F12 medium** formulations of culture media for the propagation of mammalian cells based on saline F. [Named after Richard G. Ham.]

handedness a form of terminology (based on the human left and right hands) for describing objects and compounds that are mirror images of each other and hence nonsuperimposable. A pair of **enantiomers** display molecular handedness. *See chirality*.

handle a colloquial term for any chemical group attached to a specified substance with the purpose of making it more easily identified, more reactive, or more easily operated upon, or one that may serve in targeting or specific binding. The attachment of a handle may be brought about chemically or metabolically.

handle technique a technique used to separate excess alkylating agents from products in peptide synthesis. For instance, the C terminus of a growing peptide chain can be protected with a basic function, e.g. by forming a 4-picolyl ester of the carboxyl group, thereby allowing separation of the products on cation-exchange resin columns or by extraction into aqueous acidic solutions.

Hanes plot or **Hanes–Wolf plot** a graphical method for treating enzyme kinetic data using the following form of the Michaelis equation (*see Michaelis kinetics*):

$$s/v = K_m/V + s/V$$

where s is the substrate concentration, v is the velocity of the reaction, and V is the limiting rate. If s/v is plotted against s , the slope of the resulting straight line is $1/V$, the intercept on the s/v axis is K_m/V , and the intercept on the s axis is $-K_m$. [After Charles Samuel Hanes (1903–90) and Barnet Woolf (1902–1983), British biochemists.]

hanging drop method a technique used in protein crystallization in which a droplet of protein solution, buffer, and precipitant is allowed to equilibrate with a reservoir of buffer and precipitant at higher concentration in a closed system. The name comes from the fact that the droplet hangs from a glass coverslip suspended over the reservoir.

Hanks' balanced salt solution *abbr.*: HBSS; a balanced salt solution used in tissue culture to provide a suitable ionic and osmotic environment for cell growth and development.

Hansch equation an equation relating the differences in the partitions of variously substituted compounds between an organic and an aqueous phase to the **hydrophobicity constant**, π , of the substituent. If P_0 is the ratio of the solubility of the parent compound in an organic phase to that in the aqueous phase, and P is the corresponding ratio for the substituted compound, then: $\pi = \log(P/P_0)$.

Hansenula *see methylotrophic yeasts*.

H antigen *see blood-group substance*.

HapII a type 2 **restriction endonuclease**; recognition sequence: C⁺CGG. *HpaII* and *MspI* are **isoschizomers**. The *M.HpaII* modification site is C2; *M.HpaII* is an **isoschizomer**.

haploid describing a cell, an organism or a nucleus of a cell having a single genome or a single set of homologous chromosomes; i.e. containing half the **diploid** number; having a **ploidy** of one. —**haploidy** *n*.

haplotype a set of genes located on a single chromosome; the term is used also to denote the characteristics dependent on those genes. In outbred populations the maternal and paternal chromosomes usually differ, so an individual has two haplotypes, one derived from each parent.

'happiness hormone' *a jocular name for any endorphin or enkephalin*, so-named because of the supposed ability of such substances to promote a sense of well-being.

hapt+ *a variant form of hapto+* (before a vowel).

hapt any, usually small, substance that can combine specifically with antibody but that is not immunogenic unless bound to a **carrier** (def. 8). Most haptens carry only one or two antigenic determinants. —**haptenic** *adj.*

hapt-**inhibition test** a serological test for characterizing an antigenic determinant. It involves the use of haptens of known structure to block the combining site of a particular antibody.

hapt-**sandwich labelling** a variant of the **sandwich technique** for amplification of an antigen–antibody reaction. In this modification, the primary antibody, specific for the antigen of interest, is combined with a number of residues of a hapten, e.g. *p*-azobenzene arsonate. The secondary (labelled or marked) antibody is a specific anti-hapten antibody; on reaction of secondary antibody molecules with a molecule of primary antibody, the hapten residues become sandwiched between the large molecules of antibody. By the use of different haptens and two or more non-cross-reactive anti-hapten antibodies bearing distinguishable markers, two or more antigens on the same or different cells may simultaneously be labelled.

hapticity *symbol: η*; the attribute of a ligand entity or group that combines with a central (usually metal) atom to form a coordination entity in which the central atom is bonded to two or more contiguous atoms of the ligand rather than to a specific atom. Such a coordination entity is frequently (but not exclusively) a **π adduct**. *See also hapt.*

hapt or (*less commonly*) **eta** (*in chemical nomenclature*) the name by which to read the symbol η - (Greek eta), when prefixed to the name of the ligand group in a coordination entity (with added locants if appropriate) to indicate hapticity.

hapt+ or (*before a vowel*) **hapt+** *comb. form* indicating ability to bind or combine.

haptocorrin a blood cobalamin-binding glycoprotein that may prevent uptake of bacterial cobalamin analogues.

haptoglobin *abbr.*: Hp; any α_2 globulin of blood plasma that can combine with free oxyhemoglobin to form a stable, ~300 kDa, complex. Such combinations occur when hemoglobin is liberated in the blood, and the complexes so formed, which have weak peroxidase activity and cannot be filtered by the kidney, are rapidly removed and degraded in the tissues. Three human haptoglobin phenotypes are known, designated Hp 1-1, Hp 2-2, and Hp 2-1, each of which contains two pairs of non-identical polypeptide chains, α and β , joined by disulfide bonds. There are two kinds of α chain, α_1 of 84 amino-acid residues (9 kDa) and α_2 of 143 residues (17 kDa), and a single kind of β chain, of 244 residues (in human). The α_2 chain, found solely in human haptoglobin, is identical in sequence to that of residues 1–71 or 1–72 of an α_1 chain linked to residues 11 or 12 to 84. The basic subunit structure of Hp 1-1 is $(\alpha_1\beta)_2$, that of Hp 2-2, $(\alpha_2\beta)_2$, and that of Hp 2-1, $(\alpha_2\beta)(\alpha_1\beta)$. However, the α_2 chain has an odd number of half-cystine residues; consequently, larger oligomers of Hp 2-2 and Hp 2-1 may arise by formation of disulfide bonds with α_2 chains of other molecules or of $(\alpha_2\beta)$ half-molecules.

haptomer any substance (such as a lectin or the B fragment of diphtheria toxin) that can interact with the cell membrane and that binds or can be bound to an **effector** (such as gelonin or the A fragment of diphtheria toxin), thereby allowing the effector to exert its toxic action on intact cells. —**haptomeric** *adj.*

haptophore a term introduced by Ehrlich to denote the specific chemical group in a toxin (i.e. antigen) molecule that attaches it to an antitoxin (i.e. antibody) molecule. Unlike the **toxophore**, it is not destroyed on conversion of the toxin to a toxoid.

H⁺(aq) *symbol for the hydrated hydrogen ion*, the normal state of the hydrogen ion in aqueous solutions, consisting of a hydron surrounded by a shell of water molecules held by ion–dipole interaction. *Compare oxonium* (def. 1).

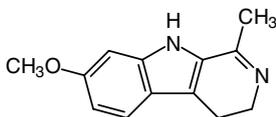

hard (*in radiation physics*) describing corpuscular or electromagnetic ionizing radiation (especially beta particles or X- or gamma-radiation) having relatively high energy, hence high ionizing power and long-range or high penetrating power. Hard X- or gamma-radiation has short wavelengths. *Compare* **soft** (def. 1).

Harden-Young ester a former name for D-fructose 1,6-bisphosphate (before its chemical structure had been elucidated). [After (Sir) Arthur Harden (1865–1940) and William John Young (1878–1942), British biochemists.]

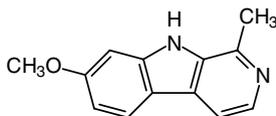

Hardy-Weinberg law a mathematical statement about the relation between gene frequencies and genotype frequencies within a population. If the genotypes are AA, Aa, and aa, and p is the frequency of allele A in the population, and q the frequency of allele a, so that $p + q = 1$, then the relative proportions of the three genotypes in the population, AA:Aa:aa, is given by $p^2:2pq:q^2$. [After Godfrey Harold Hardy (1877–1947), British mathematician, and Wilhelm Weinberg (1862–1937), German physician.]

Hardy-Weinberg population a population of randomly mating individuals in which there are no changes in allele frequencies from generation to generation. *See* **Hardy-Weinberg law**.

harmaline 4,9-dihydro-7-methoxy-1-methyl-3H-pyrido[3,4-b]indole; a cardioactive alkaloid from Syrian rue, *Peganum harmala* that also has hallucinogenic properties. *See also* **harmine**.

harmine 7-methoxy-1-methyl-9H-pyrido[3,4-b]indole; a β -carboline alkaloid found in, e.g., *Peganum harmala* (Syrian rue). It inhibits monoamine oxidase and is a central nervous system stimulant. *See also* **harmaline**.

harmonin a cytosolic protein, encoded by a gene at 11p15.1, mutations of which cause the autosomal recessive **Usher syndrome** type IC. It contains a common, highly conserved sequence of ≈ 90 residues (called a **PDZ domain**) that forms a hydrophobic pocket capable of binding the intracellular hydrophobic C-terminal residue of several transmembrane proteins and ion channels.

HART *abbr.* for hybrid-arrested translation.

Hartley filter funnel a development of the **Büchner funnel** comprising three pieces, the reservoir, a perforated plate to support the filter disk, and a conical piece to collect the filtrate. [After (Sir) Percival Hartley (1881–1957), British bacteriologist.]

Hartnup disorder a rare, autosomal recessive condition of humans in which there is a specific hyperaminoaciduria and indoluria, due to diminished renal reabsorption of monoamino-monocarboxylic acids, especially tryptophan. There may also be an impaired intestinal absorption of the same amino acids. It is often associated with a pellagra-like skin rash, which may be resolved by oral nicotinic acid. [After E. Hartnup, the first patient with the condition to be described.]

hashish a resinous extract obtained from the dried flower tops of the hemp plant (*Cannabis sativa*). The term may sometimes be used for various other extracts. *See* **cannabis**.

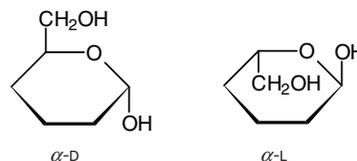

HAT *abbr.* for 1 hypoxanthine-aminopterin-thymidine (medium); a medium devised to select against cells deficient in hypoxanthine/guanine phosphoribosyltransferase (HGPRT⁻ cells). Aminopterin blocks *de novo* synthesis of purines and HGPRT⁻ cells are unable to

utilize the salvage pathway, and hence are killed. It is of particular use in the production of **hybridomas**. 2 human airway trypsin-like protease; a serine protease type II transmembrane protein (418 amino acids) of the trachea. 3 histone acetyltransferase.

hatching enzyme *see* **envelysin**.

Hatch-Slack pathway or **C₄ cycle** or **C₄ pathway** a metabolic pathway for carbon-dioxide translocation occurring in **C₄ plants**. In the mesophyll cells **phosphoenolpyruvate carboxylase** catalyses the condensation of CO₂ with phosphoenolpyruvate to form oxaloacetate; this is then reduced to malate by light-generated NADPH. The malate passes into the bundle-sheath cells where it is oxidatively decarboxylated by the **malic enzyme** to pyruvate and CO₂; the pyruvate returns to the mesophyll cells and is reconverted to phosphoenolpyruvate by ATP and pyruvate dikinase; the CO₂ remains in the bundle-sheath cells where it enters the **reductive pentose phosphate cycle**. The overall effect of the pathway is to carry CO₂ from the mesophyll cells, which are in contact with air, to the bundle-sheath cells, which are the major sites of photosynthesis.

Haworth representation a diagrammatic way of unambiguously representing the structural formulae of the cyclic forms of monosaccharides to show on a plane surface the relative configurational arrangements of the atoms and groups in space. Pyranoses are represented by a hexagon (five carbons and one oxygen) and furanoses by a pentagon (four carbons and one oxygen). A Haworth representation is derived from a **Fischer projection** as follows. The monosaccharide in question is depicted with the carbon-chain horizontal and in the plane of the paper, the potential carbonyl group being to the right. The oxygen bridge is then depicted as being formed behind the plane of the paper. The heterocyclic ring is therefore located in a plane approximately perpendicular to the plane of the paper and the groups attached to the carbon atoms of that ring are above and below the ring. The edge of the ring nearer the viewer is indicated by thickened lines. For clarity, the carbon atoms of the ring and their attached hydrogen atoms are not shown. Groups that, in the Fischer projection, appear to the right of the vertical chain then appear in the Haworth representation below the plane of the ring. However, at the asymmetric carbon atom involved via oxygen in ring formation (e.g. C-5 in glucopyranose, C-4 in glucofuranose), a rotation about the bond to the preceding carbon atom must be envisaged in order to bring that oxygen atom into the correct orientation to link to the carbon atom of the carbonyl group. Thus, if the hydroxyl group that is engaged in ring formation lies to the right in the Fischer projection, the group that lies below it must point upwards in the Haworth representation, whereas if it lies to the left, it must point down in the Haworth representation. In representing the α and β anomers in the Haworth convention, it should be noted that for the α anomer, the anomeric hydroxyl points in the opposite direction to the R group (see structure); for D-sugars, the R group points upwards, so the α -hydroxyl must point down; conversely, if the R group points down (as in α -L-glucose), the α anomeric hydroxyl must point upwards. The above rules only obtain if the ring is numbered clockwise from the anomeric carbon, as is frequently the case, and it is important to appreciate that Haworth representations, unlike Fischer projections, cannot be rotated in the plane of the paper but must be reorientated in space. [After (Sir) Walter Norman Haworth (1883–1950), British organic chemist.]

Haymann nephritis antigen an alternative name for **LRP2**.

Hb *abbr.* and symbol for hemoglobin; hence, e.g., HbO₂ symbolizes oxyhemoglobin, and HbCO symbolizes carbonmonoxyhemoglobin.

Hb A *abbr.* for adult hemoglobin.

H band *an alternative name for H zone (see sarcomere).*

HBD (*in clinical chemistry*) *abbr.* for α -hydroxybutyrate dehydrogenase, the LD₁ isoenzyme of **lactate dehydrogenase**, or 'heart-specific' lactate dehydrogenase, which is assayed using 2-hydroxybutanoate as substrate, a substance that does not occur naturally.

Hb F *abbr.* for fetal hemoglobin.

Hb S *abbr.* for sickle-cell hemoglobin; *see* **sickle cell**.

HBSS *abbr.* for Hanks' balanced salt solution.

hCG or **HCG** *abbr.* for human chorionadotropin (*see* **choriagonadotropin**).

H chain *see* **heavy chain**.

HCO *symbol for the formyl group (alternative to For).*

HCR *abbr.* for host-cell reactivation.

Hcy *symbol for a residue of the α -amino acid L-homocysteine.*

HDAG *abbr.* for hepatitis delta antigen. *See* **hepatitis**.

HDEL a four-residue motif, His-Asp-Glu-Leu, of similar function to the **KDEL** motif.

HDH *abbr.* for **histidinol dehydrogenase**.

HDL *abbr.* for high-density lipoprotein.

HDP *abbr.* for helix-destabilizing protein.

He *symbol for helium.*

head 1 the foremost or uppermost part of the body of an animal; in vertebrates it comprises the skull containing the mouth, brain, and the organs of hearing, sight, smell, and taste. **2** the part of a molecular structure that bears a specific functional group or that is polar, reactive, bulky, or in some other characteristic way differs from the remainder of the molecule. **3** *a common name for a centrifuge rotor.*

headgroup of a polar lipid, that part of the molecule that expresses its polar character. For a phospholipid, this comprises the phosphate group together with any polar entity attached to it. For a glycolipid, it comprises the carbohydrate moiety.

headspace analysis a technique used in the identification of microorganisms involving gas-chromatographic analysis of the vapour in the headspace above the specimen or culture.

heat *symbol: q or Q;* the energy possessed by a system in the form of kinetic energy of atomic or molecular translation, rotation, or vibration. It is measured in joules or calories. Heat energy can be transferred from points of higher temperature to points of lower temperature by conduction, convection, or radiation. When the temperature of a system changes, its enthalpy (heat content) changes by an amount equal to the product of its mass, specific heat capacity, and its change in temperature.

heat capacity *symbol: C;* the amount of heat required to raise the temperature of a body or a system by 1 kelvin; it is usually measured in joules per kelvin. The **heat capacity at constant pressure**, C_p , is given by: $C_p = (\partial H/\partial T)_p$, J K⁻¹ and the **heat capacity at constant volume**, C_v , is given by: $C_v = (\partial U/\partial T)_v$, J K⁻¹ where H is the enthalpy, U the internal energy, and T the thermodynamic temperature.

heat content *another name for enthalpy.*

heat-labile describing molecules that decompose at elevated temperatures or that lose biological activity when heated to a moderate temperature, e.g. 50°C.

heat of activation the difference in heat content between a transition state and the state of its reactants.

heat of combustion the amount of heat evolved when a given amount, usually one mole, of a substance is completely burnt in dioxygen.

heat of evaporation *an alternative name for heat of vaporization.*

heat of formation the amount of heat absorbed or evolved when one mole of a substance is formed from its elements.

heat of fusion or **heat of melting** the amount of heat absorbed or evolved when a specified quantity of substance, usually one mole, is converted from the solid to the liquid state at a specified pressure and a specified temperature. If the pressure is 1 atm the temperature is the melting point of the substance.

heat of neutralization the amount of heat absorbed or evolved when one mole of an acid or base is completely neutralized.

heat of reaction the amount of heat absorbed or evolved in the course of a (bio)chemical reaction, usually expressed per mole of reacting substances.

heat of solution the amount of heat absorbed or evolved when one

mole of a substance is dissolved in a large volume of specified solvent.

heat of vaporization or **heat of evaporation** the amount of heat absorbed or evolved when a specified amount of substance, usually 1 mole, is converted from the liquid to the vapour state at a specified pressure and a specified temperature. If the pressure is 1 atm the temperature is the boiling point.

heat-shock protein *abbr.:* hsp; any of a group of specific proteins that are synthesized by both prokaryotic and eukaryotic cells on exposure to temperatures that are higher than normal, or to other stresses, such as free-radical damage. Many members of the hsp family are not induced, but are normally present in all cells. Human cells in culture also produce heat-shock proteins, but induction of heat-shock proteins has not been clearly demonstrated in the body. Heat-shock proteins are classified, according to their size, into three types: Hsp60, Hsp70, and Hsp90. They are characterized by their role as molecular **chaperones**. A major chaperone in the lumen of the endoplasmic reticulum is **binding protein** (BiP), a member of the Hsp70 class. These proteins are highly conserved, those from *Escherichia coli* and humans being 50% identical in primary structure. The Hsp70 proteins possess ATPase and peptide-binding domains. The other members of the Hsp70 class are Grp75 in mitochondria, and DnaK in bacterial cytosol. Hsp60 is also found in the mitochondrial matrix; the prokaryotic orthologue of this class is GroEL (*see groEl*).

heat-shock regulatory element or **heat-shock response element** *abbr.:* HSE; a base sequence in prokaryotic and eukaryotic genomes responsible for regulating gene expression in response to heat-shock and related stress situations.

heat-shock response element *an alternative name for heat-shock regulatory element.*

heat-stable describing something that retains its (bio)chemical activity when heated to a moderate temperature, e.g. 50°C.

heavy (*in physics*) of more than the usual mass. *Compare* **light** (def. 2).

heavy atom or **heavy isotope** or **heavy nuclide** an isotopic form of an atom that contains more than the common number of neutrons and is thus of greater relative atomic mass than the most abundant or most commonly observed isotope.

heavy carbon *see* **carbon-13**.

heavy chain or **H chain** the heavier of the two types of polypeptide chain found in **immunoglobulin** molecules. Each heavy chain is linked, usually by disulfide bonds, to a **light chain** and to another, identical heavy chain. Heavy chains differ in relative molecular mass according to the type of immunoglobulin: in humans the M_r is $\approx 50\,000$ in IgG and $\approx 70\,000$ in IgM. Each heavy chain consists of an **Fc fragment** and an **Fd fragment**. Heavy chains carry the antigenic determinants that differentiate the various immunoglobulin classes.

heavy-chain disease a rare disease of humans in which there are tumours of lymphoid tissue associated with the presence of free immunoglobulin fragments in plasma and urine.

heavy-chain switch or **H-chain switch** the change in the expression of the immunoglobulin **heavy chain** (H chain) gene system as manifested by the predominance of IgM (μ chain class) in the primary immune response and by the predominance of IgG (γ chain class) in the **secondary immune response**.

heavy hydrogen *an alternative name for deuterium.*

heavy meromyosin *abbr.:* H-meromyosin or HMM; a 350 kDa fragment produced when **myosin** is subjected to tryptic digestion. It contains part of the helical, rod-shaped tail and both globular heads of the original myosin molecule, and hence retains both the ATPase and the actin-binding activity of myosin.

heavy metal a term variously applied to the salts of certain metallic elements of atomic number greater than 11, usually referring to their toxicity and preference for covalent bonding (hence calcium and magnesium are omitted). There is no agreed and consistent definition of a heavy metal.

heavy nitrogen the stable nuclide ¹⁵N (nitrogen-15); relative abundance in natural nitrogen 0.37 atom percent. It is used as a tracer in studies of nitrogen metabolism.

heavy oxygen the stable nuclide ¹⁸O (oxygen-18), usually accom-

panied by the stable nuclide ^{17}O (oxygen-17); relative abundances in natural oxygen: ^{18}O , 0.20 atom percent; ^{17}O , 0.037 atom percent. ^{18}O is used as a tracer in studies of reaction mechanisms and of oxygen metabolism.

heavy strand or **H strand** **1** any polynucleotide chain labelled with a heavy isotope, e.g. nitrogen-15. **2** any naturally occurring chain in a polynucleotide duplex that is heavier or has a greater density than the complementary strand.

heavy water deuterium oxide; *symbol*: $^2\text{H}_2\text{O}$ or D_2O ; water in which the hydrogen atoms in all of the molecules have been replaced by deuterium; or water in which the hydrogen is appreciably enriched in deuterium. The M_r of pure $^2\text{H}_2\text{O}$ is 20.028. Heavy water is prepared from natural water by exchange techniques or by fractional distillation or electrolysis. It is used as a tracer in metabolic studies, in investigation of reaction mechanisms, and as a solvent in resonance spectroscopy.

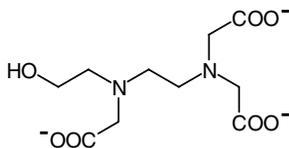

Hechtian stand a threadlike structure that connects protoplasts of plasmolysed plant cells to their cell wall. Hechtian stands are tubes of cytoplasm delineated by plasma membrane that retain tight contacts with the cell wall, possibly via integrin-type receptors or **WAK1**.

hect+ *see* **hecto+** (def. 2).

hecto+ **1** *symbol*: h; an SI prefix denoting 10^2 times. **2** or (*before a vowel*) **hect+** denoting 100 or 100 times.

hedgehog protein a transmembrane protein involved in segment polarity and cell-to-cell signalling during embryogenesis and metamorphosis in *Drosophila melanogaster*. *See also* **sonic hedgehog proteins**.

HEDTA *abbr. for* *N*-(2-hydroxyethyl)ethylenediamine triacetate, or its trisodium salt, or for its partially or fully protonated forms. It is a chelating agent, especially for ferric ions in the pH range 7.0–10.0.

height equivalent to an effective theoretical plate *abbr.*: HEETP; *symbol*: *H*; (*in chromatography*) the column length divided by the **effective theoretical plate number**.

height equivalent to a theoretical plate or **plate height** *abbr.*: HETP; *symbol*: *h*; (*in chromatography*) the column length divided by the **theoretical plate number**.

Heisenberg uncertainty principle the principle that the simultaneous precise determination of the velocity (or any related property, e.g. momentum or energy) of a material particle and its position is impossible; the smaller the particle the greater the degree of uncertainty. [After Werner Karl Heisenberg (1901–76), German physicist; Nobel Laureate in Physics (1932).]

HeLa cell an established tissue culture strain of human epidermoid carcinoma cells containing 70–80 chromosomes per cell (compared with 46 in normal cells). It is much used for biochemical work. HeLa cells have been in continuous culture since 8 February 1951, and were derived from tissue removed from a patient named Henrietta Lacks.

helical cross a name sometimes given to the X-shaped pattern of X-ray scattering from a continuous helical molecule.

helical wheel (*in protein sequence analysis*) a circular graph depicting five turns of helix (≈ 20 residues), around which residues in a protein sequence are plotted 100° apart (3.6 residues per 360° turn) for an alpha helix. Different parameters are used to depict helices with different pitches (e.g. 120° for a 3_{10} helix, 160° for beta strands). Helical wheels are particularly useful for depicting amphipathic character (recognized by the clustering of hydrophilic and hydrophobic residues in distinct polar and nonpolar arcs); however, they are not predictive.

helicase a name sometimes given to the protein (**repA**) that promotes the ATP-dependent unwinding of the parental DNA duplex during DNA replication. *See also* **DNA helicase**, **RNA helicase**.

Helicobacter pylori a Gram-negative bacterium that colonizes the human gastric mucosa and is acquired orally in infancy. There are several types and subtypes, with distinct geographical distributions. It is a common cause of gastric ulcer and gastric cancer. The major virulence factor in ulcer formation is the toxin Vac A, which, *in vitro*, disrupts gastric epithelial cell integrity in many ways. In the mouse, Vac A gastric injury is mediated by protein tyrosine phosphatase receptor z (Ptpz) of epithelial cells.

helicorubin a b-type cytochrome that occurs in the hepatopancreas of the snail *Helix pomatia* and related species.

helix (*pl. helices*) **1** a coiled or spiral structure, e.g. the thread of a bolt or a coil (tubular) spring. *See also* **alpha helix**, **beta helix**, **gamma helix**. **2** the curve traced on the surface of a cylinder or cone by a point crossing its right sections at a constant angle. **3** a space curve with turns of constant angle to the base and constant distance from the axis. —**helical** *adj.*; **helicity** *n.*

helix breaker an amino-acid residue that has a propensity to interrupt α -helical structures when it occurs in a polypeptide chain; e.g., proline (in globular proteins – in membrane proteins, proline introduces a distinctive kink, but does not break the helix), hydroxyproline. *Compare* **helix former**.

helix-destabilizing protein *abbr.*: HDP; any of a group of proteins that bind tightly and preferentially to single-stranded DNA. Theoretically, they: (1) lower the melting temperature, T_m , for thermally induced **helix-to-coil transition**; (2) lower the optimum temperature for duplex renaturation; (3) sterically hinder base pairing and degradation of single strands by nucleases; (4) induce a conformation for the single-stranded DNA that is optimal for its function in some processes, e.g. as a template in replication; and (5) interact with other proteins (enzymes) to potentiate processes involving single-stranded DNA and these proteins.

helix former an amino-acid residue that has a propensity to promote α -helical structures when it occurs in a polypeptide chain. *Compare* **helix breaker**.

helix-loop-helix *abbr.*: HLH; *an alternative term for* **helix-turn-helix**.

helix-to-coil transition the transition of a macromolecule (polypeptide or polynucleotide) from an ordered to a disordered structure; it is equivalent to **denaturation**. Helix-to-coil transitions are usually detected by monitoring a change in some physical property of the macromolecule such as intrinsic viscosity, optical absorbance, or sedimentation coefficient. *See also* **melting temperature**.

helix-turn-helix (*abbr.*: HTH) or **helix-loop-helix** (*abbr.*: HLH) a structural feature of several DNA-binding regulatory proteins consisting of two helices separated by a **beta turn**.

helix winding number *see* **supercoil**.

Helmholz free energy or **Helmholz function** *abbr.*: *F* or *A*; free energy at constant volume.

helodermin *see* **exendin**.

helospectin I *see* **exendin**.

helper cell *abbr.*: T_H cell; a **T lymphocyte**, carrying the surface markers CD4 and CD5 in the human (L3T4 and Ly1 in the mouse), that acts as an inducer of the effector cells for both **humoral** and **cell-mediated immunity**. Helper cells recognize and bind to antigen in combination with class II **major histocompatibility complex** molecules on the surface of antigen-presenting cells, and generate lymphokines that stimulate effector cytotoxic cells and B cells. Other cells of the helper phenotype, e.g. $CD4^+$ cells, are known as **T-suppressor** cells and are responsible for suppression, exerting negative feedback control on the helper cells.

helper peak-1 *abbr.*: HP-1; *a former name for* **interleukin 1**.

helper phage a bacteriophage that is capable of infecting *E. coli* cells and directing the synthesis of proteins necessary for phage replication but is itself unable to replicate owing to mutations it carries. Cloning vectors, such as lambda ZAP, which have an M13 origin of replication, can be induced to replicate in single-stranded form if the *E. coli* cells that harbour them are superinfected with helper phage.

helper virus any virus that supplies one or more of the functions

that a **defective virus** is unable to perform. When a cell is infected with both a defective virus and a helper virus, the former is able to replicate, a property that can be exploited in various molecular biological techniques.

hem+ or (*esp. Brit.*) **haem+** a variant form of **hemo+** (before a vowel).

hema+ or (*esp. Brit.*) **haema+** a variant form of **hemo+**.

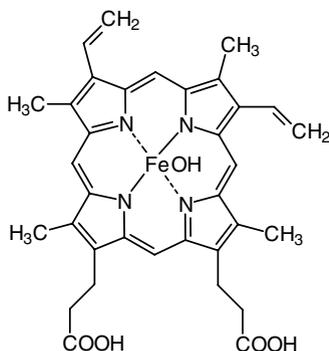

hemadsorption the adsorption of an agent or substance to or on the surface of a red blood cell.

hemagglutination or (*esp. Brit.*) **haemagglutination** the agglutination of red blood cells.

hemagglutinin or (*esp. Brit.*) **haemagglutinin** 1 any **agglutinin** of red blood cells. 2 any nonantibody substance, e.g. a lectin or a surface component of some virus particles, that can agglutinate red blood cells. 3 a viral envelope glycoprotein responsible for the attachment of virus to cell receptors and the initiation of infection.

hemat+ or (*esp. Brit.*) **haemat+** a variant form of **hemato+** (before a vowel).

hematin or (*esp. Brit.*) **haematin** 1 or **ferriheme hydroxide** the trivial name for ferriprotoporphyrin hydroxide (formerly called ferriprotoporphyrin IX hydroxide); hydroxo(protoporphyrinato) iron(III); hydroxoiron(III) protoporphyrinate. Compare **heme** (def. 1), **hemin** (def. 1). 2 the generic name for any hydroxo(porphyrinato)iron(III) coordination complex.

hemato+ or (before a vowel) **hemat+** comb. form denoting blood. Also (*esp. Brit.*): **haemato+**, **haemat+**. See also **hemo+**.

hematocrit or (*esp. Brit.*) **haematocrit** 1 or **packed red cell volume** the proportion of the volume of a sample of blood that is represented by the red blood cells. 2 an apparatus, essentially a graduated centrifuge tube, used to determine the proportion of the volume of a sample of blood that is represented by the red blood cells.

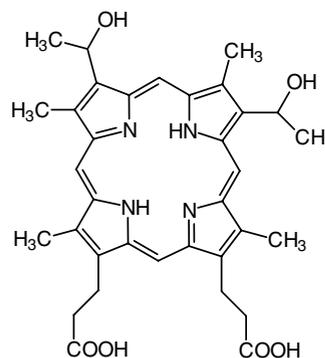

hematocrit technique a method for the rapid isolation of mitochondria or other particles, in which they are separated from the medium by centrifugation through a layer of silicone fluid. The latter is immiscible with water, and of a density intermediate between that of the particles to be separated and that of the medium. A high-density aqueous 'fixative' beneath the silicone layer can be used to stabilize labile compounds in the mitochondria or other particles. Compare **hematocrit** (def. 2).

hematology or (*esp. Brit.*) **haematology** the branch of medicine concerned with diseases of the blood or of the blood-forming tissues.

hematolysis or (*esp. Brit.*) **haematolysis** an alternative name for **hemolysis**.

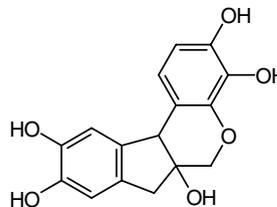

hematopoiesis or (*esp. Brit.*) **haematopoiesis** an alternative name for **hemopoiesis**.

hematoporphyrin or (*esp. Brit.*) **haematoporphyrin** or (formerly) **hematoporphyrin IX** or (*esp. Brit.*) **haematoporphyrin IX** the trivial name for 2,7,12,18-tetramethyl-3,8-bis(1-hydroxyethyl) porphyrin-13,17-dipropionic acid; the porphyrin formed from **heme** (def. 1) or a heme-containing protein on treatment with hydrogen bromide in glacial acetic acid.

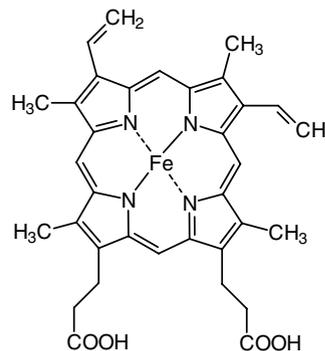

hematoside or (*esp. Brit.*) **haematoside** a **ganglioside**, NeuAc(α 2-3)Gal(β 1-4)Glc(β 1-1)Cer, found in red blood cells.

hematoxylin or (*esp. Brit.*) **haematoxylin** 7,11b-dihydrobenz[*b*]indeno[1,2-*d*]pyran-3,4,6a,9,10(6*H*)-pentol; a dye isolated from the heartwood of logwood, *Haematoxylon campechianum* L. Colourless or yellowish, it turns red on exposure to light, and is used as a stain in microscopy.

hematuria or (*esp. Brit.*) **haematuria** the presence of red blood cells in the urine. It can be due to lesions in the urinary tract, but also to glomerular disease of the kidney.

heme or (*esp. Brit.*) **haem** 1 or **ferroheme** or **ferrohaem** or **protoheme** the trivial name for **ferroprotoporphyrin** (formerly called ferroprotoporphyrin IX); 2,7,12,18-tetramethyl-3,8-divinylporphyrin-13,17-dipropionic acid iron(II) coordination complex. It occurs free and as the prosthetic group of a number of hemoproteins, e.g. hemoglobins, erythrocyruorins, myoglobins, some peroxidases, catalases, and cytochromes *b*. Compare **hematin** (def. 1), **hemin** (def. 1). 2 the generic name for any iron-porphyrin coordination complex irrespective of the valence state of the iron atom (which may be specified). The name of an individual heme is derived from that of the corresponding porphyrin; e.g., cytoheme, from cytoporphyrin, and ferroprotoheme, from protoporphyrin. For biosynthesis, see **tetrapyrrole**.

heme (def. 1)

heme-heme interaction or (*esp. Brit.*) **haem-haem interaction** the cooperative interaction between dioxygen binding sites that occurs when dioxygen binds to hemoglobin; as oxygenation proceeds, the combination of additional dioxygen molecules is made easier.

heme oxygenase *abbr.*: HO; EC 1.14.99.3; a microsomal enzyme, mostly of liver and spleen, that converts heme (in the presence of O₂) to α -hydroxyhematin, which converts noncatalytically to biliverdin and carbon monoxide. It requires NADPH and NADPH-hemoprotein reductase (EC 1.6.2.4). Three isozymes are known of which HO 1 is heme-inducible. Deficiency of HO 1 (encoded at 22q22.1) is very rare and is associated with severe anemia, high levels of circulating heme, enhanced endothelial cell damage, and early death.

heme pocket or (*esp. Brit.*) **haem pocket** a hydrophobic crevice in the tertiary structure of myoglobin, or hemoglobin subunit, into which the heme group fits. The non-polar vinyl side chains of the heme are buried in the interior of the pocket, while the hydrophilic propionate side-chains project out of the pocket towards the surface of the molecule.

heme protein or (*esp. Brit.*) **haem protein** an alternative name for hemoprotein.

hemerythrin or (*esp. Brit.*) **haemerythrin** an oxygen carrier found in a few groups of invertebrates, e.g. sipunculid worms, certain molluscs and crustaceans. It is a non-heme, iron-containing protein, the subunits of which each contain about 113 amino-acid residues. Each monomer has an active site containing two atoms of Fe(II), 0.34 nm apart, between which a dioxygen molecule is thought to fit. The molecule is a homooctamer.

heme synthetase *see* ferrochelatase.

heme-thiolate protein or (*esp. Brit.*) **haem-thiolate protein** *see* P450.

hemi+ *prefix* denoting half, or affecting one half. *Compare* semi+.

hemiacetal *see* acetal.

hemicellulose any or all of the cell-wall polysaccharides that are extractable from wood or other plant material with aqueous alkali (in which cellulose itself is insoluble). Hemicelluloses are chiefly xylans, but other homoglycans or heteroglycans containing hexose and/or pentose residues, uronic acid-containing xylans, and other **pectic substances** may also be present.

hemicystine an alternative name for half-cystine.

hemicystyl an alternative name for half-cystyl.

hemidesmosome a specialized cell junction between an epithelial cell and its underlying basal lamina. These resemble **desmosomes** morphologically but are chemically and functionally distinct. Between the cell membrane and the underlying connective tissue is a specialized mat of extracellular matrix sometimes known as the linker. The transmembrane linker proteins belong to the **integrin** family of extracellular matrix receptors rather than the **cadherin** family of cell-cell adhesion proteins found in desmosomes.

hemidiaphragm a muscle preparation widely used for metabolic studies *in vitro*, consisting of either of the two excised and separated left and right halves of the diaphragm, usually from a rat.

hemiketal *see* acetal.

Hemimetabola or **Exopterygota** one of the two divisions of the subclass Pterygota, comprising those insects, e.g. cockroaches, locusts, and grasshoppers, in which the juvenile forms resemble the adults, except for their lack of fully developed wings. Such insects undergo incomplete metamorphosis. *Compare* **Holometabola**.

hemin or (*esp. Brit.*) **haemin 1** or **ferriheme chloride** or **protohemin** the trivial name for ferriprotoporphyrin chloride (formerly called ferriprotoporphyrin IX chloride); chloro(protoporphyrinato)iron(III); chloroiron(III) protoporphyrinate. *Compare* **heme** (def. 1), **hematin** (def. 1). **2** the generic name for any chloro(porphyrinato)-iron(III) coordination complex.

hemiplegic migraine a rare familial autosomal dominant form of migraine that is marked by transient hemiplegia during the aura. It is caused by several point mutations in a gene at 19p13 for the α 1A subunit (CACNA1A, calcium channel α subunit 1A) of a voltage-gated calcium channel present in neurons. The protein contains 2261 amino acids, with four repeated domains each containing four transmembrane segments, and a polyglutamine tract in the C-ter-

минаl region. Expansion of this tract leads to episodic ataxia and to spinocerebellar ataxia type 6.

hemiport a model of translocation of solutes across membranes, based on the possibility that there is interaction through the membrane between superficially disposed protein subunits. These subunits are envisaged as being embedded within the bimolecular lipid layer, anchored to the aqueous phase, and perhaps mobile in the plane of each face of the membrane. The subunits bind the solute in question and, when associated with the symmetrical protein at the opposite face of the membrane, transfer the solute across the membrane.

hemithioacetal *see* acetal.

hemithioacetal *see* acetal.

hemizygous describing an organism in which a gene is present only once in a genotype, as a gene in a haploid cell or organism, a sex-linked gene in the heterogametic sex, or a gene in a segment of chromosome in a diploid cell or organism where its partner segment has been deleted. —**hemizyosity** *n*.

hemo+ or **hema+** or (*before a vowel*) **hem+** *comb. form* denoting blood. *Also* (*esp. Brit.*): **haemo+**, **haema+**, **haem+**. *See also* **hemato+**.

hemochromatosis or (*esp. Brit.*) **haemochromatosis** an iron overload disease of humans characterized by widespread, massive accumulation of tissue iron and pathological changes of tissue structure and function. **Primary hemochromatosis** results from increased absorption of iron from a normal diet. This is usually caused by autosomal recessive mutations in the gene for HFE, an HLA-type protein (321 amino acids) that binds β_2 -microglobulin and associates with the transferrin receptor in the gastrointestinal tract. About 10% of persons of European descent are heterozygotes for such mutations. More rarely, mutations in the transferrin receptor, or autosomal dominant mutations in the genes for ferritin H subunit or ferroportin, are the cause. **Secondary hemochromatosis** results from an increased intake and accumulation of iron secondary to other causes. *Compare* **hemosiderosis**.

hemochrome or (*esp. Brit.*) **haemochrome** any iron-porphyrin coordination complex with one or more strong-field axial ligands (e.g., pyridine).

hemochromogen or (*esp. Brit.*) **haemochromogen** any compound of heme with a nitrogenous base, such as a protein (whether native or denatured) or pyridine, typically with two absorption bands in the green part of the visible spectrum. *See also* **chromogen**.

hemocuprein or (*esp. Brit.*) **haemocuprein** an alternative name for superoxide dismutase.

hemocyanin or (*esp. Brit.*) **haemocyanin** a blue, copper-containing oxygen carrier present in many molluscs and arthropods. It is a non-heme protein that binds one dioxygen molecule for two Cu(I) atoms; the dioxygen molecule is thought to form a bridge between the two copper atoms. The oxygenated compound is bright blue, with an intensity of light absorption 5–10 times that of other known copper complexes. For example, hemocyanin from lobster, *Panulirus interruptus*, is a hexamer of a number of different chains, of which A, B (88% identity between these two), and C have been identified.

hemocyte or (*esp. Brit.*) **haemocyte** any blood cell, especially of an invertebrate animal.

hemocytometer or (*esp. Brit.*) **haemocytometer** an apparatus for counting the number of cells in a known volume of blood. It consists of a slide with a chamber of known depth; the base of the chamber is ruled with a graticule over which the cells can be enumerated under a microscope.

hemodialysis or (*esp. Brit.*) **haemodialysis** the process of separating low-molecular-mass solutes from blood by **dialysis** through a semi-permeable membrane, as in an artificial kidney machine.

hemoglobin or (*esp. Brit.*) **haemoglobin** *symbol*: Hb; any of a group of red, iron-containing, oxygen-carrying pigments of the blood of vertebrates and some invertebrates; hemoglobin also occurs in the root nodules of leguminous plants. All vertebrate hemoglobins consist of two pairs of associated **globin** polypeptide chains, each chain carrying a heme prosthetic group bound non-covalently, the iron atom of which is in the ferrous state and forms a coordination complex with the pyrrole nitrogens. All normal human hemoglobins

contain one pair of 15.7 kDa α chains, of 141 amino-acid residues, and a pair of varying 16.5 kDa polypeptide chains, of 146 amino-acid residues and of similar amino-acid sequence. In adult human blood, 98% of the total hemoglobin is Hb A (or Hb A₁), containing a pair of β chains (i.e., it has composition $\alpha_2\beta_2$) and 2% is Hb A₂, containing a pair of δ chains (i.e., $\alpha_2\delta_2$). In fetal blood, from about 10 to 30 weeks of gestation, >90% of the hemoglobin is Hb F, containing a pair of γ chains (i.e., $\alpha_2\gamma_2$). In embryonic blood, the second pair of chains are ϵ chains (i.e., the structure is $\alpha_2\epsilon_2$). Each of the four heme groups in a hemoglobin molecule is able to combine reversibly with one dioxygen molecule; the oxygen-saturation curve of hemoglobin is sigmoidal, showing that there is positive cooperativity between the subunits. The hemoglobin molecule has a two-fold axis of symmetry, each half containing one α chain and one non- α chain; the overall shape of the molecule is globular, with the heme groups buried in pockets in the polypeptide chains. There are eight helical regions, designated A to G. The histidine at position F8 (i.e., the eighth residue in helix F) is the fifth ligand of the heme Fe(II). Upon oxygenation, dioxygen becomes the sixth ligand of Fe(II), and is also hydrogen bonded to HisE7, with an accompanying conformational change. In the absence of the correct bonding with the globin side chains, Fe(II) autooxidizes to Fe(III) and can no longer bind dioxygen. Among human α chain variants are Luxembourg, Ann Arbor, and Hirosaki. Among the **hemoglobinopathies** associated with β -chain variants is **sickle-cell anemia**. In those invertebrates that have hemoglobin (not **hemocyanin**), the protein is polymeric: e.g., in earthworm hemoglobin, 12 subunits are arranged in a hexagonal bilayer structure of 3.8 MDa, each subunit of which is composed primarily of disulfide-linked trimers (chains A, B, and C) and monomers (chain D). *See also* **hemoglobin A_{1c}**.

hemoglobin A_{1c} or (*esp. Brit.*) **haemoglobin A_{1c}** *abbr.*: Hb A_{1c}; the most abundant of the **glycated hemoglobins**, which are present in normal adult hemoglobin as minor components (together, they represent 3–5% of the total hemoglobin of the erythrocyte). Hb A_{1c} is formed from Hb A₁ subsequent to biosynthesis by glycosylation of one of the two β chains, by a non-enzymic mechanism involving formation of an N-substituted aldimine (Schiff's base) between the amino group of the peptide chain and the aldehyde group of glucose, followed by an **Amadori rearrangement** to the corresponding N-substituted ketoimine (aminodeoxyfructose derivative) (*see also* **Maillard reaction**). In inadequately controlled **diabetes mellitus**, the steady-state concentration of Hb A_{1c} in serum is 2–3 times higher than normal, possibly reflecting an abnormally high mean blood glucose concentration during the preceding few months. Other glycosylated hemoglobins change very little in concentration in diabetes; thus, measurement of serum levels of Hb A_{1c} is considered to be useful in assessing the degree of control of the condition.

hemoglobinopathy or (*esp. Brit.*) **haemoglobinopathy** any genetic disorder involving globin, the protein moiety of **hemoglobin**. These are classified into **thalassemia** syndromes, caused by defective synthesis of the component polypeptides of globin, and conditions that arise from mutations leading to amino-acid substitutions in the polypeptide chains. Of the latter there are over 850 known variants, including the classically important **sickle cell hemoglobin**. Many changes lead to increased oxygen affinity, e.g. Hb Rainier (β -145, Tyr → Cys), while in others decreased oxygen affinity occurs, e.g. Hb Kansas (β -102, Asn → Thr). Many substitutions lead to an unstable hemoglobin molecule, as in Hb Hammersmith (β -42, Phe → Ser) where the important heme contact of the phenylalanine is lost, leading to the formation of **ferrihemoglobin**, or in Hb Bristol (β -67, Val → Asp) where replacement of the nonpolar valine by aspartic acid causes distortion of the E helix. Some substitutions lead to congenital methemoglobinemia, as in Hb MBoston (α -58, His → Tyr) and Hb MSaskatoon (β -63, His → Tyr). Some variant globins are elongated whereas others are shortened.

hemolin or (*esp. Brit.*) **haemolin** an insect hemolymph protein of the immunoglobulin superfamily, containing four internal immunoglobulin-type repeats. It is induced by bacteria.

hemolymph or (*esp. Brit.*) **haemolymph** a fluid occurring in the secondary body cavity (coelom) of some invertebrates, considered as functionally equivalent to the blood and lymph of higher animals.

hemolysate or (*esp. Brit.*) **haemolysate** a preparation obtained by lysis of erythrocytes.

hemolysin or (*esp. Brit.*) **haemolysin** **1** any substance, e.g. an antibody, that causes hemolysis. **2** any bacterial exotoxin that ruptures blood-cell membranes. In hemolytic *Escherichia coli* strains that cause predominantly nongastrointestinal (e.g. urinary tract) infections, four genes are involved: *hlyA* encodes hemolysin (Ca²⁺-binding toxin); *hlyB* encodes an **ABC transporter** for HlyA export; *hlyC* encodes a protein involved in hemolysin export; and *hlyD* encodes a transmembrane protein component of the HlyA export system. *Staphylococcus aureus* secretes **α -hemolysin**, a protein (293 amino acids) that binds erythrocytes and some other cells. It forms a mushroom-shaped homoheptameric channel to which each subunit contributes two antiparallel beta strands. It is responsible for the hemolysis seen around colonies grown on blood agar plates.

hemolysis or (*esp. Brit.*) **haemolysis** the lysis of red blood cells, either *in vivo* or *in vitro*. —**hemolyse** or **haemolyse** *vb*.

hemolytic or (*esp. Brit.*) **haemolytic** **1** of, or pertaining to **hemolysis**. **2** an agent or condition that causes hemolysis.

hemopexin or (*esp. Brit.*) **haemopexin** a 57 kDa β_1 -glycoprotein of human blood serum with one high-affinity binding site for **heme** (def. 1). The heme complex can be reduced with dithionite to give a three-band absorption spectrum characteristic of ferrohemeochrome. Hemopexin may be necessary for heme to be taken up and degraded in the liver.

hemophilia or (*esp. Brit.*) **haemophilia** any of various hereditary disorders in which there is a deficiency or defect in certain of the **blood coagulation** factors resulting in prolonged bleeding following injury. Classical hemophilia, or **hemophilia A**, is a condition in which the blood has a prolonged clotting time due to an abnormally slow conversion of prothrombin to thrombin. It is caused by a functional deficiency of antihemophilic factor (factor VIII), inherited as an X-linked recessive trait. Other deficiencies in the blood coagulation system, e.g. **Christmas disease**, or **hemophilia B**, due to a deficiency of factor IX, produce similar clinical pictures.

hemopoiesis or **hematopoiesis** the process of blood formation, especially the formation of blood cells, occurring mainly in bone marrow. *Also* (*esp. Brit.*): **haemopoiesis**, **haematopoiesis**. —**hemopoietic**, **hematopoietic** or **haemopoietic**, **haematopoietic** *adj*.

hemoprotein or **heme protein** any protein to which an iron-porphyrin compound is linked in a stoichiometric manner. Hemoproteins include hemoglobins, myoglobins, cytochromes, catalase, and some peroxidases. *Also* (*esp. Brit.*): **haemoprotein**, **haem protein**.

hemorphin or (*esp. Brit.*) **haemorphin** any of a group of hemoglobin-derived peptides with affinity for opioid receptors.

hemorrhage or (*esp. Brit.*) **haemorrhage** bleeding; the escape of blood from a ruptured blood vessel, either externally or internally. —**hemorrhagic** or (*esp. Brit.*) **haemorrhagic** *adj*.

hemorrhagic toxin C and D *see* **atrolysin C**.

hemosiderin or (*esp. Brit.*) **haemosiderin** an insoluble, granular, ill-defined complex formed by the denaturation of **feritin**, with associated loss of apoferritin and micellar aggregation; about one third of its mass is iron. Hemosiderin occurs in liver, spleen, and red bone marrow, its amount increasing with increased iron content of the body. It is responsible for the histochemical staining of tissue by the Prussian Blue reaction, a deep-blue ferric ferrocyanide (Fe_{III}[Fe_{II}(CN)₆]). The distribution of stored iron is shifted from ferritin to hemosiderin in direct correlation with ascorbic acid deficiency. *See* **iron overload**.

hemosiderosis or (*esp. Brit.*) **haemosiderosis** an abnormal increase in tissue iron content due to some defect in the control of iron turnover in the body or to increased iron ingestion. In a rare pulmonary form, recurrent bleeding into the lungs loads the macrophages with hemosiderin and produces diffuse fibrosis. Hepatic hemosiderosis is common in alcoholic cirrhosis. *Compare* **hemochromatosis**.

hemostasis or (*esp. Brit.*) **haemostasis** **1** the stopping of bleeding or the arrest of the circulation to an organ or part. **2** the stagnation of blood in an organ or part.

hemostat or (*esp. Brit.*) **haemostat** a device or a chemical agent that stops or retards bleeding.

hemostatic or (*esp. Brit.*) **haemostatic** **1** of, relating to, or function-

ing to cause **hemostasis** (def. 1). **2** a drug or other agent that retards or stops bleeding.

Henderson–Hasselbalch equation an equation relating pH to the composition of buffer solutions:

$$\text{pH} = \text{p}K_{\text{A}} + \log([\text{conjugate base}]/[\text{acid}]),$$

where $\text{p}K_{\text{A}}$ is the common logarithm of the acid dissociation constant of the buffer acid. The following approximation is often used:

$$\text{pH} = \text{p}K_{\text{A}} + \log([\text{salt}]/[\text{acid}]).$$

[After Lawrence Joseph Henderson (1878–1942), US physician and biochemist, and Karl A. Hasselbalch (1874–), Danish biochemist, who together formulated the equation in 1910.]

henna a preparation obtained from the dried and powdered leaves of *Lawsonia alba*, *L. inermis*, or *L. spinosa*, widely used for dyeing hair and fingernails. The active ingredient is **lawsone**.

henry (*pl.* **henrys** or **henries**) *symbol:* H; the SI derived unit of inductance, equal to the inductance of a closed circuit with a **magnetic flux** of 1 weber per ampere of current,

$$H = \text{Wb A}^{-1} \text{ s} = \text{m}^2 \text{ kg s}^{-2} \text{ A}^{-2}$$

[After Joseph Henry (1797–1878), US physicist.]

Henry's function a function used in the theoretical treatment of the electrophoretic mobility of macromolecules that is dependent on the radius of the macromolecule, r , and its reciprocal ion-atmosphere radius, κ (derived from **Debye–Hückel theory**). It varies between 1.0 and 1.5 as κr goes from zero to infinity.

Henry's law the principle that the concentration of a gas in solution, at constant temperature, is directly proportional to the partial pressure of the gas in the vapour phase in equilibrium with that solution. It holds with high precision for gases of low solubility at pressures below approximately 10^5 Pa. It may be expressed by: $c_{\text{G}} = kp_{\text{G}}$, where c_{G} is the molar concentration of the gas in solution, p_{G} is the partial pressure of the gas in the gas phase, and k is a proportionality constant. [After William Henry (1774–1836), British chemist.]

HEPA filter a high-efficiency particulate air filter used, for example, in removing bacteria and other particulates from air in safety cabinets.

heparan any polysaccharide derived by desulfation of **heparan sulfate** or **heparin**.

heparan sulfate any member of a group of glycosaminoglycans that have repeat units consisting of alternating $\alpha 1 \rightarrow 4$ -linked hexuronic acid and glucosamine residues, the former being a mixture of sulfated and nonsulfated D-glucuronic and L-iduronic acids, and the latter being either sulfated or acetylated on its amino group as well as sulfated on one of its hydroxyl groups. They usually occur attached to protein to form proteoglycans, the mode of attachment being through a xylose residue as in **chondroitin sulfates**. Heparan sulfate accumulates in a number of the mucopolysaccharidoses, e.g. Hunter syndrome, Hurler syndrome, and Sanfilippo syndrome. *See* **mucopolysaccharidosis**. *See also* **heparin**.

heparan sulfate proteoglycan core protein *abbr.:* HSPG core protein; any of a group of modular heparan sulfate proteoglycan proteins with three heparan sulfate chains. Also known as **perlecan**, they contain domains that share similarity with the low-density lipoprotein receptor, epidermal growth factor, laminin and neural cell adhesion molecule, and have 15 immunoglobulin-like domains.

heparin any glycosaminoglycan found mainly in mast cells. Heparins are similar to **heparan sulfates** but somewhat larger (6–20 kDa) and with fewer *N*-acetyl groups and more *N*-sulfate and *O*-sulfate groups; they are proteoglycans. They consist predominantly of alternating $\alpha 1 \rightarrow 4$ -linked D-galactose and *N*-acetyl-D-glucosamine-6-sulfate residues. Heparins are secreted into the bloodstream by the mast cells of liver, lung, and other tissues; they act as inhibitors of blood clotting by activating **antithrombin III**. Commercial heparins are protein-free.

heparin cofactor II a plasma glycoprotein that is homologous with **antithrombin III** but, of the proteases involved in coagulation, only inhibits thrombin. Its physiological role is obscure, but its activity is stimulated by dermatan sulfate and by heparin. The gene at 22q11 encodes 480 amino acids.

heparinize or **heparinise** to treat with a preparation of **heparin**, usually as its sodium or lithium salt, in order to prevent clotting, either *in vivo* or *in vitro*, of blood or blood plasma. —**heparinization** or **heparinisation** *n*.

hepat+ a variant form of **hepato+** (before a vowel).

hepatectomy surgical removal of the liver. In **partial hepatectomy**, only some of the lobes of the liver are removed; this causes the remaining lobes to regenerate so that the liver *in toto* regains its former weight. —**hepatectomize** or **hepatectomise** *vb*.

hepatic of, or pertaining to, the liver.

hepatic lipase EC 3.1.1.3; an enzyme that hydrolyses triacylglycerols and phosphoproteins present in chylomicron and very-low-density lipoprotein remnants. It is a glycoprotein synthesized and secreted by hepatocytes, and binds to proteoglycans on hepatocyte surfaces and on sinusoidal endothelial cells. It also binds LDP (LDL receptor-like protein). The gene at 15q21 encodes 499 amino acids. Rare inactivating mutations in the gene result in an autosomal recessive syndrome of hepatic lipase deficiency.

hepatitis any inflammatory disease of the liver. In humans the most common cause is infection with a virus or an amoeba. Hepatitis A is caused by a single-stranded RNA **picornavirus**, for which there is a killed virus vaccine, virus having been grown in tissue culture. Hepatitis B is caused by a double-stranded DNA virus of the Hepadnaviridae family forming a spherical virion often referred to as the **Dane particle**. It is especially virulent and is associated with the development of primary liver tumours – the incidence of these is particularly high in China. The antigens may be in the form of spherical particles designated HBsAg; principal components include gp27, which is a glycosylated form of p24, and a 42 kDa protein. HBsAg is produced in recombinant yeast, the particles being similar to those found in the plasma of infected individuals and providing a very effective vaccine. Hepatitis C, formerly called 'non-A non-B', is caused by a single-stranded RNA virus, for which there is no vaccine. Hepatitis D virus is a satellite virus of hepatitis B virus and contains a circular single-stranded RNA genome (≈ 1700 nt). Its replication requires the antigen HDag – the only protein encoded by the virus – and RNA polymerase II. HDag-S (195 amino acids) activates replication of the virus. HDag-L is the former with a 19-residue C-terminal extension; it inhibits replication and directs assembly of the virion. HDag-S shares 21% sequence identity with NELF-A. Other forms are hepatitis E, F, and G.

hepato+ or (before a vowel) **hepat+** *comb. form* denoting of or pertaining to the liver.

hepatocarcinogen any **carcinogen** that acts specifically or primarily on liver.

hepatocellular of, or pertaining to **hepatocytes**.

hepatocyte or (formerly) **parenchymal liver cell** the major (but not the only) cell type of the liver. They are arranged in folded sheets facing blood-filled spaces called sinusoids. Hepatocytes are responsible for the synthesis, degradation, and storage of a wide range of substances. They are the site of synthesis of all the plasma proteins, except for antibody, and are the site of storage of **glycogen**.

hepatocyte growth factor *abbr.:* HGF; *other name:* scatter factor; a **cytokine** produced by platelets, fibroblasts, macrophages, endothelial cells, and smooth muscle cells that is a potent **mitogen** for hepatocytes, epithelial cells, keratinocytes, melanocytes, and hematopoietic precursor cells. It is a glycoprotein, with four **kringle** domains and no known protease activity. The molecule is a disulfide-linked dimer of α (463 amino acids) and β (234 amino acids) subunits, which are derived from a common precursor.

hepatocyte growth factor receptor a type I membrane protein that binds **hepatocyte growth factor** and mediates its intracellular action by a protein tyrosine kinase (EC 2.7.1.112) activity on its intracellular domain. It is encoded by the **MET** protooncogene, and comprises a dimer of two subunits, α and β . *See also* **tpo-met**.

hepatocyte nuclear factor *abbr.:* HNF; any of several transcription factors involved in activation of numerous liver-specific genes. Some are also present in pancreatic islet cells. **HNF-1 α** is a homeobox transcription factor that requires dimerization cofactor (DCoH; *see* **pterin-4 α -carbinolamine dehydratase**) for dimerization and stabilization. Numerous mutations in HNF-1 α are associated with maturity-onset diabetes of the young (MODY) type 3. **HNF-**

1β is homologous with HNF-1α, and also requires DCoH for dimerization and stabilization. Several mutations are associated with MODY type 5. **HNF-4α** belongs to the nuclear receptor superfamily, and is a major regulator of hepatic gene expression and of HNF-1α. Mutations are associated with MODY type 1.

hepatoflavin or **hepatoflavine** a former name for **riboflavin**.

hepatolenticular degeneration an alternative name for **Wilson's disease**.

hepatoma any **carcinoma** derived from liver cells.

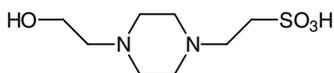

hepatopancreas a digestive gland, found in many invertebrates, that performs functions similar to those of the liver and the pancreas in vertebrates.

hepatosis any noninflammatory disease of the liver.

hepatotoxin any toxin that acts specifically or primarily on the liver.

hepcidin a peptide hormone with antimicrobial activity that regulates uptake and storage of iron. Elevated levels of hepcidin are associated with iron deficiency.

Hepes or **HEPES** *abbr. for (and trivial name of) 4-(2-hydroxyethyl)-1-piperazine-ethanesulfonic acid*; a **Good buffer substance**, pK_a (20°C) = 7.55.

HepG2 a cell line derived from a patient with primary liver cancer.

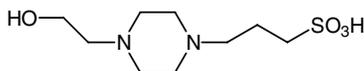

hephaestin a membrane-bound homologue of ceruloplasmin that is required, with **ferroportin**, for the transport of iron across the basolateral plasma membrane of mucosal cells of the upper small intestine. It appears to act as a ferroxidase ($Fe^{2+} \rightarrow Fe^{3+}$) in the process. A hereditary sex-linked anemia occurs in mice in which the gene is mutated.

HEPN domain *abbr. for higher eukaryotes and prokaryotes nucleotide-binding domain*; a protein sequence (≈ 110 amino acids) whose prototype is in the C-terminal region of **sacsin**. It is present in proteins from several vertebrates and many eubacteria and archaea. Because it is similar to a domain present in many kanamycin nucleotidyltransferases it is thought to mediate nucleotide binding.

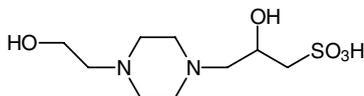

hepoxilin *abbr.:* Hx; any of various epoxyhydroxy metabolites of 12-hydroperoxyeicosatetraenoate, e.g. 13-hydroxy-14,15-epoxyeicosatetraenoate. A number of sites of formation have been reported, with activities including modulation of neurotransmission in brain and release of insulin in pancreatic islets.

hepoxilin-epoxide hydrolase EC 3.3.2.7; an enzyme that converts (5Z,9E,14Z)-(8ζ,11R,12S)-11,12-epoxy-8-hydroxyeicosa-5,9,14-trienoate (**hepoxilin A₃**) to the trioxilin, (5Z,9E,14Z)-(8ζ,11ζ,12S)-8,11,12-trihydroxyeicosa-5,9,14-trienoate (**trioxilin A₃**).

Hepps or **HEPPS** or **EPSPS** *abbr. for (and trivial name of) 4-(2-hydroxyethyl)-1-piperazinepropanesulfonic acid*; a **Good buffer substance**, pK_a (20°C) = 8.0.

Heppso or **HEPPSO** *abbr. for (and trivial name of) 4-(2-hydroxyethyl)-1-piperazine-(2-hydroxypropanesulfonic acid)*; a **Good buffer substance**, pK_a (25°C) = 7.8.

hepsin EC 3.4.21.-; a serine protease, similar to other trypsin-like

enzymes, that is a type II membrane protein. It is required for growth and maintenance of cell morphology in many tissues.

hepta+ or (*before a vowel*) **hept+** *comb. form* denoting seven.

heptad a seven-residue pseudorepeat in an alpha-helical segment of a polypeptide. In coiled coils, positions a and d of the heptad contain nonpolar residues. In leucine zippers, position g contains leucine.

heptanoate **1** the anion, $CH_3-[CH_2]_5-COO^-$, derived from heptanoic acid (formerly enanthic acid). **2** any salt or ester of heptanoic acid.

heptanoyl *symbol:* Hpo; the univalent acyl group, $CH_3-[CH_2]_5-CO-$, derived from heptanoic acid.

heptitol any **alditol** having a chain of seven carbon atoms in the molecule.

heptose any **aldose** having a chain of seven carbon atoms in the molecule.

heptulose any **ketose** having a chain of seven carbon atoms in the molecule.

heptyl *symbol:* Hp; the alkyl group, $CH_3-[CH_2]_5-CH_2-$, derived from heptane.

heptyl glucoside *n*-heptyl β -D-glucopyranoside; a nonionic detergent, CMC 79 mM.

heptyl thioglucoside *n*-heptyl 1-thio- β -D-glucopyranoside; a nonionic detergent; the CMC, 30 mM, remains unchanged between 1 and 20°C.

HER2 *see neu*.

herbicide any chemical substance that destroys plants or inhibits their growth, especially one used to control weeds.

hereditary of, pertaining to, or caused by **heredity**; inherited.

hereditary angioedema or **angioneurotic edema** or **C1 inhibitor deficiency** an autosomal dominant condition characterized by episodes of swelling, primarily of the face, extremities, larynx, or abdomen. The attacks may be triggered by emotional stress and can prove fatal. It is caused by deficiency of **C1 inhibitor**, which may be absent (in type I disease) or some 30% of normal (in type II). The C1 inhibitor gene at 11q11 contains 17 Alu sequences, which mediate the gene deletions responsible for most type I cases. Mutations that lead to a dysfunctional protein are common in type II disease.

hereditary disease any pathological condition that is caused by the presence in the organism of an abnormal gene.

hereditary fructose-bisphosphatase deficiency an inherited autosomal recessive condition in humans characterized by less than 20% of normal activity of **fructose-bisphosphatase** (EC 3.1.3.11). It is characterized in infants by episodic spells of hyperventilation, apnoea, hypoglycemia, ketosis, and lactic acidosis. Surviving infants appear to become normal, but gluconeogenesis in their livers is severely impaired, and when glycogen stores are depleted, amino acids, lactate, and ketones accumulate. Subjects are not sensitive to fructose intake. *Compare* **hereditary fructose intolerance**.

hereditary fructose intolerance a condition in humans, inherited as an autosomal recessive character, in which there is a deficiency of the aldolase-B isoenzyme of **fructose-bisphosphatase aldolase** (EC 4.1.2.13) (there is less than 15% normal activity with fructose 1,6-bisphosphate as substrate but activity is less depressed with fructose 1,6-bisphosphate as substrate) while the levels of aldolases A and C are normal (*see* **aldolase** (def. 2)). The condition is characterized by severe hypoglycemia and vomiting shortly after fructose intake. In this condition prolonged fructose ingestion in infants leads to poor feeding, vomiting, hepatomegaly, jaundice, hemorrhage, proximal-renal-tubule syndrome, and death. The hypoglycemia ensuing after fructose ingestion is caused by fructose 1-phosphate inhibition of glycogenolysis at the phosphorylase level and of gluconeogenesis at the mutant aldolase level. *Compare* **hereditary fructose-bisphosphatase deficiency**.

hereditary hemorrhagic telangiectasia *see* **activin receptor-like kinase 1**.

hereditary multiple exostoses *abbr.:* HME; *other names:* multiple osteochondromata; osteochondromatosis; diaphyseal aclasia; familial bony spurs. An inherited disease in which numerous exostoses (bony spurs) develop (usually around the knee, but also at the shoulder, wrist, and on the ribs) as a result of a disorder of the growth plate.

hereditary persistence fetal hemoglobin a benign condition in which there is continued production of hemoglobin F in adults. Some cases are caused by deletion of the β - and δ -globin loci. Non-deletion phenotypes are characterized by point mutations in the promoter region of one or the other γ -globin genes.

heredity 1 the transmission from one generation to another of genetic factors that determine the characteristics of an organism. **2** all of the inherited factors in an organism or all the characteristics determined by them.

heregulin *abbr.*: HRG; one of several glycoproteins that bind to the transmembrane tyrosine kinase ErbB2 p185, and stimulate its activity. They are secreted by human breast cancer cells in culture.

hormone *an alternative term for hormone* (suggested by E. Schäfer in 1913 as better expressing the concept of chemical messengers).

heroin *see* diacetylmorphine, morphine.

herpes virus any of a family (Herpesviridae) of enveloped, icosahedral, double-stranded DNA viruses, many of which infect animals. The family includes human herpesviruses types 1 and 2, Epstein-Barr virus, zoster (varicella) virus, pseudorabies virus, cytomegalovirus, Lucke virus, and Marek's disease virus.

herrings any marine fish of the family Clupeidae, the flesh of which is comparatively rich in oils with a high content of long-chain *n*-3 fatty acids; typical composition (range of major fatty acids, expressed as % of total fatty acids): 16:0, 12–18%; 16:1(*n*-7), 6–8%; 18:1(*n*-9), 11–25%; 20:1(*n*-9), 7–19%; 20:5(*n*-3), 11–15%; 22:6(*n*-3), 5–8%.

Hershey-Chase experiment a seminal experiment, reported in 1952, in which it was demonstrated that when an *Escherichia coli* cell is infected with T2 bacteriophage, the phage DNA is injected into the cell whereas the phage coat protein remains on the outside of the infected bacterial cell. This was shown by demonstrating that most of the ^{35}S -labelled phage protein could be removed from the surface of the bacterial cells by application of a shearing force without removing the ^{32}P -labelled nucleic acid and without interfering with the course of productive infection. The phage nucleic acid could be shown to have moved into the bacterial cell. It was therefore concluded that only the phage DNA was required for infection, indicating that DNA must be the hereditary material. This confirmed earlier experiments in 1944 by Avery and colleagues (*see* transforming principle), but was somewhat more readily accepted when Watson and Crick deduced the structure of DNA. [After Alfred Day Hershey (1908–97), US geneticist, and Martha Chase (1927–).]

Hershey circle a circular duplex DNA structure in which each strand contains one interruption and in which the interruptions are not opposite each other. It is formed by some linear, double-stranded DNA molecules (e.g. from *Escherichia coli* phage λ) containing short, complementary single strands (cohesive ends) at each end when these cohesive ends base-pair with each other.

Hers's disease *an alternative name for* type VI glycogen disease.

hertz *symbol*: Hz; the SI derived unit of frequency of a periodic phenomenon, equal to 1 cycle per second; i.e. $1\text{ Hz} = 1\text{ s}^{-1}$. [After Heinrich Hertz (1857–94), German physicist.]

Hess's law of constant heat summation the statement that the enthalpy change in a chemical reaction is the same whether the reaction takes place in one stage or in more than one stage. [After Germain Henri Hess (1802–50), Genevese-born Russian chemist; known in Russia as German Ivanovich Gess.]

HETE *abbr. for* hydroxyeicosatetraenoate; *see also* dihydroxyeicosatetraenoate.

hetero+ *comb. form 1* other, different, unusual. *Compare* allo+ (def. 1), homo+ (def. 1), iso+ (def. 1), xeno+ (def. 1). **2** for, from, or directed towards a different species. *Compare* allo+ (def. 2), homo+ (def. 2), iso+ (def. 2), xeno+ (def. 2). **3** containing atoms, groups, linkages, residues, or subunits of different kinds. **4** being or pertaining to an atom other than the predominant or significant one, especially of a nitrogen, oxygen, or sulfur atom in a ring containing mainly carbon atoms. *Compare* homo+ (def. 4).

heteroantibody any antibody (including any autoantibody) that is able to react with an antigen derived from another species. *Compare* isoantibody.

heteroantigen any antigen derived from one species that is able to

stimulate an immune response in another species. *Compare* isoantigen.

heteroatom any atom in the chain or ring of an organic compound that is not a carbon atom. —**heteroatomic** *adj.*

heterobifunctional describing any reagent that carries two differing reactive groups. *Compare* homobifunctional.

heterocaryon *a variant spelling of* heterokaryon.

heterochromatic 1 relating to or possessing more than one colour; relating to light or other electromagnetic radiation of more than one frequency. *Compare* monochromatic. **2** of, relating to, or possessing heterochromatin.

heterochromatin a condensed form of chromatin, occurring in the nucleus at interphase, that stains strongly with basophilic dyes. The DNA of heterochromatin is replicated at a later stage in the cell-division cycle than euchromatin. 'Satellite' DNA is associated with heterochromatin, and the sex chromosomes of animals, especially the Y chromosome, contain large regions of heterochromatin. *Compare* euchromatin.

heteroconjugation the association between a base and the conjugate acid of a different base through a hydrogen bond. *See* conjugate acid-base pair. *Compare* homoconjugation.

heterocycle any compound or molecular structure that is heterocyclic (def. 1); a heterocyclic (def. 2).

heterocyclic 1 describing any cyclic molecular structure containing atoms of at least two different elements in the ring or rings; describing any compound having such a structure. *Compare* carbocyclic (def. 1), homocyclic (def. 1). **2 or heterocycle** any such compound.

heterocyst any of the clear cells that occur at intervals on the filaments of certain cyanobacteria. They are usually the sites of nitrogen fixation in species that carry out the reaction. They have thickened cell walls and lack photosystem II and oxygenic photosynthesis.

heterodetic describing a cyclic peptide in which the ring consists of amino-acid residues only, but the linkages forming the ring are not solely eupeptide bonds; one (or, if non-proximate, more than one) is an isopeptide, disulfide, ester, or other bond. *Compare* homodetic.

heterodimer any molecular structure in which two nonidentical subunits are associated. *Compare* dimer, homodimer.

heteroduplex 1 any double-stranded DNA in which the two strands do not have completely complementary base sequences. In a mutational heteroduplex a mutational event has occurred in one of the polynucleotide chains; such a molecule does not produce uniform progeny on replication. A recombinational heteroduplex is a double-stranded DNA molecule that gives rise to one parental and one recombinant molecule of DNA in the reproductive cycle that immediately follows its production. Heteroduplex DNA may also arise from annealing DNA single strands *in vitro*. **2** a DNA-RNA hybrid. *Compare* homoduplex.

heteroduplex analysis a method of detecting mutations by the formation of heteroduplex DNA from complementary but non-identical DNA strands. When a single-stranded DNA molecule anneals to one in which there is a mismatch at one or more base pairs, the resultant heteroduplex has an electrophoretic mobility that is lower than those of homoduplexes formed from the wild-type or the mutant sequences.

heteroduplex mapping the physical mapping of the base sequence homology of two DNA molecules. It is accomplished after the *in vitro* formation of a hybrid double-stranded molecule, in which one polynucleotide strand is from one of the DNA molecules and the complementary polynucleotide strand is from the other. Unpaired single-stranded regions are located and measured by electron microscopy.

heterogametic describing the sex whose cell nuclei contain a pair of dissimilar sex chromosomes. The heterogametic sex is usually male in mammals but is female in the Lepidoptera, birds, reptiles, some amphibians and fishes, and a few plants. *Compare* homogametic.

heterogeneous 1 differing in kind, as in a heterogeneous population. **2** describing a group of molecules that is not uniform with respect to size, charge, structure, or other property. **3** describing a system consisting of two or more phases. *Compare* heterogenous. —**heterogeneity** *n.*

heterogeneous catalysis any catalytic system in which the catalyst constitutes a different phase from that of the reactants. *Compare* **homogeneous catalysis**.

heterogeneous immunoassay any form of **immunoassay** that involves physical separation, at some stage of the procedure, of antibody-bound antigen from remaining free antigen. It includes **radioimmunoassay**. *Compare* **homogeneous immunoassay**.

heterogeneous nuclear ribonucleoprotein *abbr.*: hnRNP; particulate complexes of **heterogeneous nuclear RNA** (hnRNA) with proteins, which are cell-specific and themselves heterogeneous. The protein component may play a role in the processing of the hnRNA to mRNA.

heterogeneous nuclear RNA *abbr.*: hnRNA or HnRNA or H-RNA; a heterogeneous mixture of RNA molecules of high M_r with a rapid turnover rate that occurs in cell nuclei during protein synthesis. It is the form of RNA synthesized in eukaryotes by RNA polymerase II, i.e. that which is translated into protein. It represents the transcription products of both the exons and the introns of a gene or genes and is processed to form mRNA by the removal of the nontranslated portions (corresponding to the introns in the DNA). So-named because heterogeneity in size was one of the first characteristics used to distinguish it from other forms of nuclear RNA.

heterogenesis the production of offspring having different characteristics in successive generations; e.g. the alternation between generations that produce gametes and those that reproduce through agametes or by parthenogenesis.

heterogenetic describing chromosome pairing during meiosis when the pairing partners are derived from different original ancestors. *Compare* **homogenetic**.

heterogenic 1 describing a population or a gamete containing more than one allele of a particular gene. **2** describing two genetic elements that are not known to have a common ancestry. **3** *an alternative word for* **heterogenous**. *Compare* **homogenic**.

heterogenize or **xenogenize** to introduce a foreign, especially a more potent, antigen into a cell surface in order to enhance the response by T lymphocytes to other cell-surface antigens. —**heterogenization** *n*.

heterogenous or **heterogenic** not originating within the organism in question; of foreign origin. *Compare* **heterogeneous**.

heteroglycan or **heteropolysaccharide** any polysaccharide (i.e. glycan) that contains residues of two or more kinds of monosaccharide (i.e. glucose) molecule. *Compare* **homoglycan**.

heterograft or **heterologous graft** *an alternative name for* **xenograft**. *Compare* **homograft**.

heteroimmune describing a pair of bacteriophages in which each is sensitive to its own repressor but not to that of the other.

heterokaryon or **heterocaryon** any cell with more than one nucleus, in which the nuclei are not all of the same genetic constitution, or a tissue composed of such cells. *Compare* **homokaryon**. —**heterokaryotic** or **heterocaryotic** *adj*.

heterokaryosis or **heterocaryosis** the association of genetically different nuclei in a common cytoplasm.

heterolactic fermentation a type of fermentation of glucose in which the products include lactate, acetate and/or ethanol, and carbon dioxide. A key enzyme in the pathway is **phosphoketolase**, which cleaves xylulose 5-phosphate (produced by the pentose phosphate pathway) to D-glyceraldehyde 3-phosphate and acetyl phosphate, the former being then converted to lactate while the latter can form acetate and/or ethanol. Organisms that ferment in this manner include *Leuconostoc* spp. and some species of *Lactobacillus*; some produce D(-)-lactate while others produce DL-lactate. *Compare* **homolactic fermentation**.

heterolipid *a former name for* any complex lipid.

heterologous 1 consisting of different elements or of like elements in different proportions. **2** or **heterospecific** derived from another species, e.g. heterologous serum or tissue. *Compare* **homologous**, **isologous**.

heterologous association describing any association between two **protomers** in which the **domain of bonding** is made up of two different **binding sets**. *Compare* **isologous**.

heterologous desensitization *see* **desensitization**.

heterologous graft or **heterograft** *an alternative name for* **xenograft**.

heterolysin any antibody or other hemolysin formed in response to the introduction of erythrocytes from another species into the bloodstream of an animal. *Compare* **autolysin**, **homolysin**.

heterolysis 1 (*in chemistry*) the cleavage of a bond in such a manner that both bonding electrons remain within one of the two fragments between which the bond is broken; e.g. $A-B \rightarrow A^+ + B^-$. *Compare* **homolysis**. **2** (*in biochemistry*) the lysis of cells or tissues by the action of exogenous agents, e.g. enzymes, detergents, or lysins. *Compare* **autolysis**. —**heterolytic** *adj*.

heterolysosome any early **secondary lysosome** concerned with the digestion of exogenous material (i.e. **heterophagy**). *See* **heterophagosome**.

heteromorphic or **heteromorphous 1** differing from the normal form, e.g. in size, shape, or function. **2** describing the members of any pair of homologous chromosomes that differ from each other in size or shape. **3** (*especially of insects*) having differing forms at different stages of the life cycle. **4** *an alternative term for* **polymorphic**. *Compare* **isomorphic**. —**heteromorphism** or **heteromorphy** *n*.

heteronuclear NMR a form of **nuclear magnetic resonance spectroscopy** that exploits the spin-spin interactions between different nuclear spins in a molecule. For determination of structures of proteins, the isotopes ^{13}C , ^{15}N are introduced into the sample, and the interactions between the spins of these nuclei and ^1H are probed by sequences of pulses at the appropriate frequencies.

heterooligomer any **oligomer** made up of two or more kinds of constitutional repeating unit. —**heterooligomeric** *adj*.

heterophagosome any **phagosome** containing material exogenous to the cell. Fusion with a lysosome leads to the formation of a heterolysosome. *Compare* **autophagosome**.

heterophagy the process by which cells digest exogenous material that they have taken up. *Compare* **autophagy**. —**heterophagic** *adj*.

heterophilic binding (*of adhesion molecules*) binding of an adhesion molecule in one cell to a non-identical adhesion molecule in an adjacent cell. *Compare* **homophilic binding**.

heteroplasmy the presence of more than one type of mitochondrial DNA in a cell. A mutant mitochondrial DNA may be present in varying amounts so that phenotypic variation between cells is possible.

heteroploid describing a cell that contains any number of chromosomes except the **haploid** or **diploid** number. The term includes all **aneuploid** or **polyploid** numbers of chromosomes.

heteropolymer any polymer made up of two or more kinds of constitutional repeating unit. Proteins are typical heteropolymers. —**heteropolymeric** *adj*.

heteropolysaccharide *an alternative term for* **heteroglycan**.

heteroside *a former name for* any glycoside containing a noncarbohydrate moiety (aglycon).

heterospecific having specificity for or derived from a different species; **heterologous** (def. 2).

heterotetramer any molecular structure that can be dissociated into four (or two pairs of) nonidentical monomers. —**heterotetrameric** *adj*.

heterotope any of two or more chemical elements having atoms of different atomic number and occupying different places in the periodic table. The term includes **isobar** (def. 1). *Compare* **isotope**.

heterotopia or **heterotopy** the displacement, or unusual position, of a cell, organ, tissue graft, etc.

heterotopic 1 (*in chemistry*) of, relating to, or being a **heterotope** or heterotopes. *Compare* **isotopic**. **2** (*in biology and medicine*) or **heterotopous** displaced or in an unusual anatomical position.

heterotopic transplant any tissue graft that is transplanted from its normal position to another in the same organism. *Compare* **orthotopic transplant**.

heterotopous *a variant form of* **heterotopic** (def. 2).

heterotopy *a variant form of* **heterotopia**.

heterotrimer any molecular structure that is dissociable into three nonidentical monomers. —**heterotrimeric** *adj*.

heterotroph or **heterotrophe** or **organotroph** any organism whose nutritional requirements are not satisfied solely by simple inorganic substances and for which a supply of organic carbon is required for the synthesis of cellular constituents. Heterotrophs may be sub-

divided into **chemoheterotrophs** (or chemoorganotrophs) and **photoheterotrophs** (or photoorganotrophs) according, respectively, to whether they are **chemotrophs** or **phototrophs**. *Compare autotroph.* —**heterotrophic** *adj.*; **heterotrophy** *n.*

heterotropic 1 describing an **allosteric** effect in which interaction occurs between nonidentical ligands; the effect may be either cooperative or antagonistic. The term is applied also to such an interaction, to an allosteric enzyme for which different substances act as the substrate and the effector, to the regulation of such an allosteric system, etc. *Compare homotropic. 2* describing a chromosome that does not pair with another at meiosis, especially a sex chromosome in the heterogametic sex.

heterotypic pertaining to, or being the first, reductive division in **meiosis**. *Compare homeotypic.*

heterozygosis 1 the union of genetically different gametes to form a **heterozygote. 2** or **heterozygosity** the state or condition of being a heterozygote. *Compare homozygosis.*

heterozygosity *an alternative term for heterozygosis* (def. 2).

heterozygote any cell or organism having two different genes (alleles) at one or more corresponding loci on homologous chromosomes. With respect to such loci a heterozygote will produce two different types of gametes. *Compare homozygote.*

heterozygous or **heterozygotic** of, pertaining to, or being a **heterozygote**; hybrid.

HETP *abbr.* for height equivalent to a theoretical plate.

heuristic describing any method for solving mathematical or other problems for which no **algorithm** (or closed method) exists. It involves narrowing down the field of search for a solution by inductive reasoning from past experience of similar problems. *Compare stochastic.*

HEV *abbr.* for high-walled endothelium of the post-capillary venules.

hevein an *N*-acetyl-D-glucosamine- and *N*-acetyl-D-neuraminic acid-binding lectin; it is present in the latex of the rubber tree, *Hevea brasiliensis*, and shares 56% similarity with wheat germ agglutinin.

hexa+ or (before a vowel) **hex+** *comb. form* denoting six, sixfold, six times.

hexabrachion a six-armed structure, characteristic of the **tenascin** molecule. Regions of the protein radiate outwards like spokes of a wheel. [From *L. brachium* arm.]

hexadecadienoic acid any straight-chain fatty acid having sixteen carbon atoms and two double bonds per molecule. (*all-Z*)-Hexadeca-6,9-dienoic acid is found in small amounts in some animal lipids.

hexadecanoic acid *the systematic name for palmitic acid; see palmitate.*

hexadecenoic acid any straight-chain fatty acid having sixteen carbon atoms and one double bond per molecule. The most common are the 9*Z*-isomer (palmitoleic acid; *see palmitoleate*) and the 11*Z*-isomer, but the 3*E*-, 6*E*-, 6*Z*-, 9*E*-, and 10*Z*-isomers are also variously found in animals or plants; the 9*E*-isomer (i.e. palmite-laidic acid) is a pheromone.

hexaethyleneglycol mono-*n*-decyl ether a nonionic detergent; *see C_xE_y.*

hexaethyleneglycol mono-*n*-dodecyl ether a nonionic detergent; *see C_xE_y.*

hexagonal phase (of phospholipids) a phase in which the polar headgroups are orientated towards the interior of a phospholipid aggregate, with the fatty acyl carbon chains pointing outwards; a form of inverted micelle. It can occur in lipid bilayers, especially at higher temperatures. Certain phospholipids, such as phosphatidylethanolamine, have a greater tendency to adopt this phase than, e.g., phosphatidylcholine. A hexagonal phase with the polar headgroups oriented towards the exterior of the micelle can also exist. *See also liquid-crystalline phase, phase transition.*

hexakisphosphate *see multiplying prefix.*

hexamer 1 any oligomer consisting of six monomers. **2** the group of six capsomeres in an icosahedral virus capsid.

hexanoate or **caproate 1** the anion, CH₃-(CH₂)₄-COO⁻, derived from hexanoic acid. **2** any salt or ester of hexanoic acid.

hexanolamino-PAF 1-*O*-hexadecyl-2-*O*-acetyl-*sn*-glycero-3-phospho-(*N,N,N*-trimethyl)-hexanolamine; a substance that inhibits the effects induced by **platelet activating factor**, including: platelet aggrega-

tion, secretion, and inositol phospholipid turnover; superoxide ion and H₂O₂ release from macrophages; hepatic glycogenolysis; and vasoconstriction.

hexanoyl or (formerly) **caproyl** *symbol:* Hxo; the univalent acyl group, CH₃-(CH₂)₄-CO-, derived from hexanoic acid. *See caproyl* (def. 2).

hexaric acid an **aldaric acid** formally derived from a hexose by oxidation at both C-1 and C-6.

hexitol any **alditol** having a chain of six carbon atoms in the molecule.

hexokinase EC 2.7.1.1; *systematic name:* ATP:D-hexose 6-phosphotransferase; *other name* (used for hexokinase IV): glucokinase; the phosphotransferase enzyme that catalyses the phosphorylation by ATP of D-hexose to form D-hexose 6-phosphate and ADP. In vertebrates there are four major isoenzymes, types I-IV, or A-D. All are relatively nonspecific with respect to sugar, and phosphorylate a number of hexoses such as glucose, fructose, and mannose. Thus the name glucokinase for type IV may mislead. Types I-III all have *M_r* ≈ 100 kDa and are sensitive to glucose 6-phosphate (*abbr.*: Glc-6-*P*). They differ from yeast hexokinases (≈50 kDa), which are not inhibited by Glc-6-*P*. Type III is inhibited by excess glucose. Type IV is a monomer associated with cytoskeletal actin filaments and shows cooperativity with respect to glucose. In hepatocytes, at less than 5 mM glucose it is inactive, being bound to a regulatory protein; a glucose concentration of 15 mM causes translocation and activation of the enzyme in the nucleus, where it regulates expression of several genes. For example, hexokinase type IV from human mitochondrial outer membrane has a sequence with similar N-terminal and C-terminal halves. The regulatory function is associated with the N-terminal half. Type II is the major isoenzyme of skeletal muscle and adipose tissue. There are strong sequence similarities between the different types. Mutations in glucokinase produce maturity-onset diabetes of the young (MODY).

hexon a **capsomere** that is surrounded by six other capsomeres in an icosahedral virus capsid.

hexonic acid any monocarboxylic acid (i.e. aldonic acid) formally derived from a hexose by oxidation at C-1.

hexosamine any aminodeoxy sugar with six carbon atoms.

hexosaminidase EC 3.2.1.52; *recommended name:* β-*N*-acetylhexosaminidase; *systematic name:* β-*N*-acetyl-D-hexosaminide *N*-acetylhexosaminohydrolase; *other name:* β-hexosaminidase. An enzyme that catalyses the hydrolysis of terminal nonreducing *N*-acetyl-D-hexosamine residues in *N*-acetyl-β-D-hexosaminides. It is a lysosomal enzyme in mammals. In humans there are two precursors, α and β. The α chain, a glycoprotein, comprises amino acids 109-529 of its precursor. The β precursor gives rise to three glycoproteins (all similar to α): β (amino acids 122-556), β-B (amino acids 122-311), and β-A (amino acids 315-556). There are three forms of the enzyme: form A, responsible for degradation of GM₂ gangliosides, is a trimer composed of one α chain, one β-A chain, and one β-B chain; form B is a tetramer of two β-A and two β-B chains; form S is a homodimer of two α chains. **Tay-Sachs disease** is due to defects of the α chain and Sandoff disease due to defects of the β chain.

hexosan *a former name for any of a class of polysaccharides that yield only hexoses on hydrolysis.*

hexose any **aldose** having a chain of six carbon atoms in the molecule.

hexose diphosphate pathway *an alternative name for Embden-Meyerhof pathway.*

hexose monophosphate pathway or **hexose monophosphate shunt** *an alternative name for pentose phosphate pathway.*

hexose phosphate transport protein an integral membrane transport protein responsible for sugar phosphate uptake in bacteria.

hexose-1-phosphate uridylyltransferase *see UDP-glucose-hexose-1-phosphate uridylyltransferase.*

hexulose any **ketose** having a chain of six carbon atoms in the molecule.

hexuronic acid 1 any monocarboxylic acid (i.e. uronic acid) formally derived from a hexose by oxidation at C-6. **2** *a historical name originally used for ascorbic acid.*

hexyl *symbol*: Hx; the alkyl group, $\text{CH}_3\text{--}[\text{CH}_2]_4\text{--CH}_2\text{--}$, derived from hexane.

hexyl glucoside hexyl β -D-glucopyranoside; a mild nonionic detergent, CMC 250 mM.

Hf *symbol* for hafnium.

HFBA *abbr.* for heptafluorobutyric acid; a reagent used in automatic peptide sequence analysis. It renders the action of cyanogen bromide specific to the cleavage of tryptophanyl peptide bonds.

HFCS *abbr.* for high fructose corn syrup.

Hfr *abbr.* for high-frequency recombinant.

HFT *abbr.* for high-frequency transduction.

Hg *symbol* for mercury.

HGF *abbr.* for **1** hepatocyte growth factor. **2** hyperglycemic-glycogenolytic factor; *see* **glucagon**.

HGF receptor *see* **hepatocyte growth factor receptor**.

HGG *abbr.* for human gamma-globulin.

hGH or **HGH** *abbr.* for human growth hormone (i.e. human somatotropin).

HGI *abbr.* for human gene index.

HGPRT *abbr.* for hypoxanthine/guanine phosphoribosyltransferase. *See* **hypoxanthine phosphoribosyltransferase**.

HhaI a type 2 **restriction endonuclease**; recognition sequence: GCG \uparrow C.

HHH syndrome *see* **ornithine transporter 1**.

HHT *abbr.* for hydroxyheptadecatrienoic acid.

5-HIAA *abbr.* for 5-hydroxyindoleacetic acid.

Hid a proapoptotic protein of *Drosophila* and a functional homologue of mammalian **Diablo**. It binds and inactivates **IAP** thereby releasing any associated caspase. *See* **apoptosis**.

hidden (immunological) determinant or **cryptodeterminant** any antigenic determinant so positioned that it is cryptic, i.e. normally not accessible for recognition by lymphocytes or antibody, but that becomes accessible after some stereochemical change occurs, e.g. by breakage, decomposition, or denaturation of the antigen. *See* also **cryptotope**.

hidden Markov model *abbr.*: HMM; (*in sequence alignment*) a probabilistic model that encodes the residue conservation within an aligned domain, used to provide a diagnostic signature for that domain. HMMs are linear chains of "states" in which a match state allows a sequence to match a conserved column in an alignment; an insert state allows insertions relative to match states; and delete states allow match positions to be skipped (i.e. denote deletions in a sequence relative to the alignment). HMMs form the basis of **Pfam** (*see* **pattern database**). *Compare* **profile**.

hide the skin of an animal, especially the tough, thick skin of larger mammals. Powdered, dried hide is used in assays of some proteases.

HIDS *abbr.* for hyper-IgD syndrome.

HIF *abbr.* for hypoxia-inducible factor; a transcription factor that is stable under conditions of oxygen deficiency but is targeted for degradation in the presence of oxygen. **HIF α** contains an oxygen-dependent degradation domain in which a specific prolyl residue becomes modified by a HIF prolyl-4-hydroxylase. It forms a heterodimer with **HIF β** (i.e. ARNT) and binds a 5 bp response element in hypoxia-inducible genes responsible for increasing oxygen delivery or facilitating adjustment to hypoxic stress. *See* **HIF-PH**.

HIF-PH *abbr.* for hypoxia-inducible factor prolyl hydroxylase; a prolyl-4-hydroxylase enzyme that hydroxylates a specific proline residue in the HIF α subunit (*see* **HIF**) in the presence of O_2 . The reaction promotes binding of HIF to the tumour suppressor VHL protein and thereby polyubiquitination and degradation of HIF by proteasomes.

high-density lipoprotein *abbr.*: HDL; one of the classes of lipoprotein found in blood plasma in many animals (data normally relate to humans). They are also known as *a* lipoproteins, from having the highest electrophoretic mobility of the lipoproteins. HDL particles are the smallest of the blood lipoproteins: diameter 7.5–10 nm; solvent density for isolation 1.063–1.21 g mL⁻¹; hydrated density 1.21 g mL⁻¹. Their approximate composition (% by weight) is 6% unesterified cholesterol, 13% esterified cholesterol, 28% phospholipid, 3% triacylglycerol, 50% protein. Their apolipoprotein composition (% by weight total apolipoprotein) is 67% A-I, 22% A-

II, 5–11% C-I + C-II + C-III, 1–2% E-II + E-III + E-IV, trace of D. They are synthesized in liver as precursor molecules, which undergo modification in plasma to the mature molecules, especially as a result of the action of **lecithin-cholesterol acyltransferase**. They appear to function in reverse transport of cholesterol from tissues to liver. *See* also **apolipoprotein** for individual apolipoproteins.

high-energy bond *symbol*: ~; *a term formerly sometimes used by biochemists for a chemical bond whose hydrolysis is accompanied by an unusually large (>20 kJ mol⁻¹) negative standard free energy change. Although long used, the term has been recognized as incorrect and misleading, since it suggests that such a bond actually contains an unusually large amount of energy and fails to take into account the various factors that contribute to the large negative free energy change.*

high-energy compound *a term formerly sometimes applied by biochemists to any compound containing one or more so-called high-energy bonds, e.g. ATP, phosphoenolpyruvate, acetyl-coenzyme A, etc.*

high-frequency recombinant any bacterial strain that has a high frequency of recombination because the **F plasmid** has become incorporated into the bacterial chromosome. *See* also **Hfr**.

high-frequency transduction *abbr.*: HFT; any **transduction** in which the transducing phage(s) constitute a large proportion of the total phage population.

high-fructose corn syrup *abbr.*: HFCS; a mixture of fructose and glucose used as a sweetener in soft drinks, etc.; it is sometimes called **high fructose syrup** or, especially in Europe, **isoglucose**. The breakdown of corn starch to glucose (plus oligosaccharides) is followed by the action of **glucose isomerase** yielding a mixture consisting mainly of fructose and glucose. The product thus manifests the greater sweetness of fructose compared with glucose. The content is typically 42% fructose, 51% glucose, 5% maltose, and 2% other oligosaccharides.

highly conserved *see* **conserved**.

highly repetitive DNA a form of DNA that consists of short tandemly repeated sequences. It is found outside coding regions, and its role is unknown. Such DNA forms a significant proportion of most mammalian genomes.

high mobility group proteins *abbr.*: HMG proteins; small nuclear proteins that bind to nucleosomal DNA, and probably maintain genes in a transcribable conformation. The name derives from their behaviour on electrophoresis.

high-performance capillary electrophoresis electrophoresis through a long coiled capillary column that gives very high resolution of e.g. peptides. *See* also **capillary electrophoresis**.

high-performance liquid affinity chromatography *abbr.*: HPLAC; a technique that combines the use of bioaffinity supports and **high-pressure liquid chromatography**.

high-performance liquid chromatography *abbr.*: HPLC; *an alternative name for high-pressure liquid chromatography*.

high-potential iron-sulfur protein *abbr.*: Hipip or HiPIP; a type of **ferredoxin**, originally found in the photosynthetic bacterium *Chromatium vinosum*, that has a very much higher redox potential (E_0 -0.3 V) and different magnetic properties compared with other ferredoxins. It contains a [4Fe-4S] cluster that can be oxidized to the 3+ oxidation state. Other proteins, to which the term has been mistakenly applied, contain [3Fe-4S] clusters; like the *Chromatium* protein, they are able to achieve a paramagnetic higher oxidation level, but do not have high redox potentials.

high-pressure liquid chromatography or **high-performance liquid chromatography** *abbr.*: HPLC; a technique of **column chromatography** that is rapid and provides high resolution. It can be used with the various modes of liquid chromatography, the liquid being forced at high pressure, normally up to 420 kg cm⁻² (6000 psi), through the column (which is usually of stainless steel) and thence through a detector into a fraction collector. Because of the ability to use high pressures, the particles of the support materials used for the stationary phase can be of very small diameter (3–10 μm), which greatly improves resolution.

high-scoring segment pair *abbr.*: HSP; in BLAST searches, an unpaired local pairwise alignment between arbitrary but equal-length fragments of a query and a database sequence that scores

above a user-defined threshold. HSPs are the fundamental unit of BLAST output. *See alignment algorithm.*

high-speed supernatant a jargon term for the supernatant resulting from high-speed centrifugation ($\approx 100\,000\text{ g}$).

high-spin complex any of the complex transition-metal ions having a maximal number of unpaired electrons in the d- or f-shell. This state occurs when pairing energy is higher than the crystal field splitting energy. *Compare low-spin complex.*

high-throughput describing a process that is scaled up, usually via increased levels of automation using robots. For instance, **high-throughput screening** refers to the rapid *in vitro* screening of large numbers of compound libraries (of tens to hundreds of thousands of compounds), using robotic screening assays. **High-throughput sequencing** involves the application of rapid sequencing technology at the scale of whole genomes.

high-throughput genomic sequence *abbr.*: HTG; a division of the GenBank database that provides access to unfinished genomic sequence. Its records might typically contain all of the first-pass sequence data generated from a single cosmid, BAC, YAC, or P1 clone.

high-throughput screening *see high throughput.*

high-throughput sequencing *see high throughput.*

high-voltage electron microscope a type of electron microscope that employs accelerating voltages of 1 MeV, ten times that of previous instruments, enabling images of thick sections and even intact cells to be produced without significant loss of resolution.

high-voltage electrophoresis *abbr.*: HVE; a technique of paper or thin-layer electrophoresis that results in better and more rapid separations (10–60 min) than the standard technique, which suffers from minimal diffusion of low- M_r components. The high-voltage technique employs currents of up to 500 mA and potential gradients of up to 200 V cm^{-1} . The high field strength requires cooling of the support and adequate protection devices to be incorporated into the apparatus.

Hildebrand solubility parameter *symbol*: δ ; a measure of the polarity of a solvent; nonpolar solvents have low δ values while polar solvents have large values. In liquid–liquid chromatography the Hildebrand parameter indicates the relative position of a solvent in an eluotropic series. The parameter is the sum of a number of factors:

$$\delta = \delta_d + \delta_o + \delta_a + \delta_h,$$

where δ_d quantifies interactions due to **dispersion forces**, δ_o quantifies interactions due to dipole interactions, δ_a quantifies the ability of the solvent to interact as a hydrogen acceptor, and δ_h quantifies its interactions as a hydrogen donor. [After Joel Henry Hildebrand (1881–1983), US chemist.]

Hill coefficient or **Hill constant** *symbol*: h or n_H ; *see Hill equation* and **Hill plot**.

Hill equation 1 an equation,

$$y = K[x]^h / (1 + K[x]^h),$$

used to express the binding of a ligand to a (macro)molecule. It may be rearranged to give:

$$\log[y/(1-y)] = -\log K + h \log[x],$$

where y , the **fractional saturation**, is the fraction of the total number of binding sites occupied by ligand, $[x]$ is the free (unbound) ligand concentration, K is a constant, and h is the Hill coefficient. **2** (*in pharmacology*) an equation derived from the above relating the effect of a drug to its concentration. For an effect, E , produced when an agent, A , is applied at a concentration $[A]$, then the relationship between E and $[A]$ may often be described empirically by the equation

$$E/E_{\max} = [A]^h / ([A]_{50}^h + [A]^h),$$

where E_{\max} is the maximal value of E and $[A]_{50}$ is the concentration that produces an effect that is 50% of E_{\max} . [After (Sir) Archibald Vivian Hill (1886–1977), British physiologist and biophysicist.]

Hill–Langmuir equation (*in pharmacology*) a variation of the **Langmuir absorption isotherm**; for a ligand, L , binding to a receptor, R , according to the equilibrium

$$p_{LR} = [L]/(K_L + [L]),$$

where p_{LR} is the fraction (proportion) of binding sites occupied by a ligand at equilibrium and K_L is the dissociation equilibrium constant.

Hill plot a plot of the **Hill equation** in the form $\log[y/(1-y)]$ against $\log[x]$, where y is the fractional saturation with ligand and $[x]$ is the free (unbound) ligand concentration. The slope at any one point, h , is the Hill coefficient at that value of y . The values of h along the plot, which usually do not exceed the number of binding sites on each molecule and which tend to unity as y tends to 0 or 1, give an indication of the nature and degree of cooperativity (interaction) between the various binding sites on the molecule. [After (Sir) Archibald Vivian Hill (1886–1977), British physiologist and biophysicist.]

Hill reaction the phenomenon in which isolated chloroplasts evolve dioxygen when illuminated in the presence of a suitable electron acceptor, e.g. ferricyanide or ferrioxalate, with a concomitant reduction of the electron acceptor. [After Robert ('Robin') Hill (1899–1991), British plant biochemist.]

Hill reagent any electron acceptor that functions in a **Hill reaction**, e.g. ferrioxalate or ferricyanide.

HincII a type 2 **restriction endonuclease**; recognition sequence: GT[TC]↑[AG]AC. *HincII* is an **isoschizomer**.

HindIII a type 2 **restriction endonuclease**; recognition sequence: A↑AGCTT. The *M.HindIII* modification site is C1.

HinfI a type 2 **restriction endonuclease**; recognition sequence: G↑ANTC.

hinge region 1 a flexible, proline-rich region of an **immunoglobulin** molecule, adjacent to the two disulfide bonds linking the two heavy chains together. It probably acts as a hinge on which the **Fab fragments** can rotate allowing the immunoglobulin molecule to take up a Y-shape when it reacts with antigen. The hinge region is near the sites of action of papain and pepsin. **2** the region in the helical, rod-shaped part of a **myosin** molecule that is susceptible to cleavage by trypsin to give light meromyosin and heavy meromyosin. **3** a region in any protein about which rigid body motions occur.

HinII a type 2 **restriction endonuclease**; recognition sequence: G[AG]↑CG[TC]C. *AcyI* and *BbiII* are **isoschizomers**.

Hipip or **HiPIP** *abbr.* for high-potential iron–sulfur protein.

hippocalcin a neuron-specific Ca^{2+} -binding protein with **EF-hands**, similar to recoverin. It is expressed exclusively in the pyramidal layer of the hippocampus.

Hirschsprung disease a congenital megacolon that may occur alone or be part of a syndrome. *See glial cell-derived neurotrophic factor*. [After Harald Hirschsprung (1830–1916), Danish physician.]

hirudin a dried extract obtained from leeches, and possessing anticoagulant activity. The name is also applied to the purified active component, a 65-amino-acid polypeptide with three disulfide bridges; this has highly specific antithrombin properties, inactivating thrombin by blocking substrate-binding groups.

hirudisin a recombinant **hirudin** variant engineered to inhibit α -thrombin and exhibit **disintegrin** activity. Hirudisins have antiplatelet aggregation activity. Replacement of the hirudin sequence Ser-Asp-Gly-Glu (residues 32–35) by Arg-Gly-Asp-Ser (RGDS) yields hirudisin, or by Lys-Gly-Asp-Ser yields hirudisin-1. The integrin-binding RGD motif of hirudisin is implicated in its antiplatelet action.

hirulog any synthetic peptide based on **hirudin** and designed as an inhibitor of the thrombin catalytic site, and exhibiting specificity for the anion-binding site of thrombin.

hirustasin an **antistatin**-like serine proteinase inhibitor isolated from the medicinal leech, *Hirudo medicinalis*.

His *symbol* for a residue of the α -amino acid **L-histidine** (alternative to H).

hist+ a variant form of **histo+** (before a vowel).

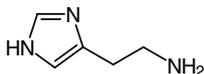

His-tag *abbr.* for histidine tag; a short sequence of six histidine residues placed at either the N- or C-terminus of recombinant proteins expressed in bacteria or mammalian cells. Proteins tagged in this way can be purified by Ni^{2+} chelate chromatography.

His-tag antibody a preparation of monoclonal or polyclonal anti-

bodies raised to 6 × His sequences used in the immunodetection and immunoprecipitation of His-tagged proteins. See **His-tag**.

histaminase see **amine oxidase (copper-containing)**.

histamine 2-(4-imidazolyl)ethylamine, formed by the decarboxylation of L-histidine and present in many mammalian tissues, including the brain and spinal cord, with especially high concentrations in lung, skin, and intestine; it is stored in the granules of tissue mast cells and circulating basophil cells. Histamine is a potent vasodilator, increases capillary permeability, causes contraction of smooth muscle, regulates gastric secretion, and mediates allergic and anaphylactic conditions.

histamine receptor any membrane receptor in mammalian tissues that binds specifically with **histamine**. **H1 receptors** mediate the stimulating effects of histamine on smooth muscle in the gut and bronchi and most of the depressor effects on blood pressure. They are G-protein-associated receptors that activate phospholipase C, and are antagonized by such classical **antihistamines** as pyrilamine (mepyramine) and promethazine. **H2 receptors** mediate the stimulation of gastric acid secretion, the increase in the contraction frequency of cardiac muscle, the increase in cyclic AMP stores in basophil and mast cells, the inhibition of release of histamine by mast cells, and some depressor effects on blood pressure. They are G-protein-associated receptors that stimulate adenylate cyclase, and are antagonized by, e.g., **cimetidine**. **H3 receptors** are G-protein-associated receptors linked to Ca²⁺ channels. They occur predominantly in presynaptic nerve terminals, attenuate the release of neurotransmitters (e.g. histamine, acetylcholine, and norepinephrine), and are antagonized, e.g., by thioperamide and clobenpropit.

histamine-releasing factor *abbr.*: HRF; a protein (172 amino acids) produced by the lymphocytes of atopic children and present in the blood of allergic individuals. It causes the release of histamine only from basophilic cells that have IgE bound to them, and may have an important role in chronic allergic diseases.

histatin any member of a family of histidine-rich peptides found in human saliva and having antibacterial and antifungal activity.

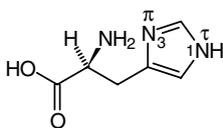

histidase an alternative name for **histidine ammonia-lyase**.

histidinal α -amino- β -4-imidazolepropionaldehyde; 2-amino-3-(1H-imidazol-4-yl)propanal; (C₃H₃N₂)CH₂-CH(NH₂)-CHO; the α -amino-aldehyde analogue of histidine. It is the immediate biosynthetic precursor of histidine.

histidinase an alternative name for **histidine ammonia-lyase**.

histidinate **1** histidine anion; the anion, (C₃H₃N₂)CH₂-CH(NH₂)-COO⁻, derived from histidine. **2** any salt of histidine anion. **3** any ester of histidine.

histidine the trivial name for β -4-imidazolylalanine; α -amino- β -imidazole-4-propionic acid; 2-amino-3-(1H-imidazol-4-yl)propanoic acid; (C₃H₃N₂)CH₂-CH(NH₂)-COOH; a chiral α -amino acid. L-Histidine (*symbol*: H or His), (S)-2-amino-3-(1H-imidazol-4-yl)propanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: CAC or CAU (anticodon: GUG). It is also a component of the isopeptide **carnosine**. In mammals, it is an essential dietary amino acid, and is glucogenic. D-Histidine (*symbol*: D-His or DHis), (R)-2-amino-3-(1H-imidazol-4-yl)propanoic acid, is not known to occur naturally. N-1 and N-3 of the imidazole ring are designated τ and π respectively.

L-histidine

histidine ammonia-lyase EC 4.3.1.3; *systematic name*: L-histidine ammonia-lyase; *other names*: histidase; histidine α -deaminase; histidinase. An ammonia-lyase (deaminase) enzyme of liver and (in some mammals) skin that catalyses the deamination of L-histidine to urocanate. It is unusual in having dehydroalanine, probably derived from a serine residue, in its active site. It is widely distributed in animals, plants, and microorganisms; in plants it is present in **glyoxysomes**. The rat, mouse, and human enzymes each contain 657 amino acids. The activity of this enzyme is defective in **histidinemia**.

histidine (base) a histidine residue in which the imidazole group is unprotonated.

histidine decarboxylase *abbr.*: HDC; EC 4.1.1.22; *systematic name*: L-histidine carboxy-lyase. A pyridoxal phosphate homodimeric enzyme that catalyses the decarboxylation of L-histidine to histamine. It is present in mast cells, enterochromaffin-like cells, and histaminergic neurons that project from the posterior hypothalamus to most parts of the brain and spinal cord. It is similar to dopa and glutamate decarboxylases.

histidine kinase *abbr.*: HK; any member of a superfamily of protein kinases specific for histidine residues. In prokaryotes and lower eukaryotes they are involved in two-component signal transduction. Most are integral membrane homodimeric proteins that contain a periplasmic N-terminal sensing domain of variable sequence, and a highly conserved cytoplasmic C-terminal kinase domain. They usually autophosphorylate (using ATP as the phosphoryl group donor) one of their own histidine residues and then transfer the group to an aspartate residue of a response regulator (RR) protein. **Hybrid histidine kinases** contain an RR – or histidine-containing phosphotransfer (HPT) – domain as part of their own structure. HKs belong to a structural class distinct from that of serine/threonine and tyrosine kinases.

histidinemia or (*esp. Brit.*) **histidinaemia** a rare, autosomal recessive, generally benign metabolic disorder in which abnormally high levels of histidine are present in the blood and urine. It is due to deficient activity of **histidine ammonia-lyase**.

histidine tail a sequence of about six histidine residues that is deliberately introduced at the C terminus of certain recombinant proteins to allow purification of the recombinant product by a type of affinity chromatography using a nickel chelating resin. Only the histidine-tailed proteins are retained by the column and these may then be eluted using a buffer containing imidazole.

histidinium 1 a term normally used to mean histidinium(1+); the (imidazolium) monocation of histidine. In theory, the term denotes any ion, or mixture of ions, formed from histidine, and having a net charge of +1, although the species (C₃H₄N₂⁺)CH₂-CH(NH₃⁺)-COO⁻ generally predominates in practice. **2** the *systematic name* for histidinium(2+); the dication of histidine.

histidinol 1 N²-histidino; the alkylamino group, (C₃H₃N₂)CH₂-CH(COOH)-NH-, derived from histidine by loss of a hydrogen atom from its α -amino group. **2** either of the two possible groups, N^π-histidino or N^τ-histidino, HOOC-CH(NH₂)-CH₂-(C₃H₂N₂)-, derived from histidine by loss of a hydrogen atom from its position on one or other of the nitrogen atoms of the imidazole ring.

histidinol 4-(2-amino-3-hydroxypropyl)imidazole; 2-amino-3-(1H-imidazol-4-yl)propanol; (C₃H₃N₂)CH₂-CH(NH₂)-CH₂OH; the α -amino-alcohol analogue of histidine. It is an intermediate, together with its phosphate ester, in the biosynthesis of histidine, and a powerful reversible inhibitor of protein synthesis.

histidinol dehydrogenase *abbr.*: HDH; EC 1.1.1.23; L-histidinol:NAD⁺ oxidoreductase. A homodimeric enzyme that catalyses the reaction:

this being the last step in the biosynthesis of histidine. The *his* operon of *Salmonella typhimurium* encodes a bifunctional protein that also has an aldehyde dehydrogenase site, histidinol being an intermediate. See also **Salmonella mutagenicity test**.

histidyl the acyl group, (C₃H₃N₂)CH₂-CH(NH₂)-CO-, derived from histidine.

histo+ or (*before a vowel*) **hist+** *comb. form* denoting tissue.

histochemistry the chemistry of the tissues, as studied with a combination of the methods of chemistry and histology.

histocompatibility the extent to which an organism will tolerate a graft of a foreign tissue. —**histocompatible** *adj.*

histocompatibility antigen any of the genetically determined **isoantigens** present on the surface of many animal cells that determine the immune reactions to tissue grafts. If tissue is grafted onto a recipient of the same species that does not carry the same histocompatibility antigens as the graft material, an immune response may be provoked in the recipient leading to graft rejection. *See also* **HLA histocompatibility system, major histocompatibility complex.**

histocompatibility gene any gene determining the formation of a **histocompatibility antigen**. *See* **HLA histocompatibility system, major histocompatibility complex.**

histoelectrofocusing a technique in which an unfixed frozen section of tissue, 25–40 μm thick, is applied to a support gel and then subjected to **electrofocusing**. The proteins and enzymes present in the tissue move into the gel and may be revealed by staining or zymographic techniques.

histogram a diagram representing a frequency distribution. It consists of a number of contiguous rectangles whose widths are proportional to the class interval under consideration and whose heights are proportional to the frequency associated with each class.

histohematin or (*esp. Brit.*) **histohaematin** a term first used in 1884 by Charles Alexander MacMunn (1852–1911) for the pigments now known as **cytochromes**. It included **myohematin**.

histone any of a group of evolutionarily highly conserved basic proteins, molecular mass 11–21 kDa, that constitute about half the mass of the chromosomes of all eukaryotic cells, except spermatozoa. They comprise single polypeptide chains with a lysine-plus-arginine content of about 25%, and are concerned in the packing of DNA in **chromatin**. The principal histones may be classified into five types, as shown in the table.

Type	Other names	Lys/Arg ratio	M_r	Location
H1	F1,Ia	20.0	21 000	linker
H2A	F2a2,IIb1	1.25	14 500	core
H2B	F2b,IIb2	2.25	13 800	core
H3	F3,III	0.72	15 300	core
H4	F2a1,IV	0.79	11 300	core

The octomer (H2A,H2B,H3,H4)₂ forms the **nucleosome** core. H1 is associated with nucleosomes, especially the linking DNA. *See also* **H-NS.**

histone acetyltransferase EC 2.3.1.48; an enzyme that transfers an acetyl group from acetyl-CoA to a lysine residue in the N-terminal region of a core histone in a nucleosome. Type A enzymes are cytosolic and acetylate freshly synthesized histones before they enter the nucleus. Type B are nuclear and reside in large multiprotein complexes, being recruited by, and acting as cofactors for, many DNA sequence-specific transcription factors. Examples include p300/CBP (which targets histones H2A, H2B, H3, and H4) and **PCAF** (which targets histones H3 and H4).

histone code the hypothesis that the pattern of acetylation, methylation, phosphorylation, and ubiquitination of the N-terminal regions of core histones within nucleosomes is recognized by proteins (or complexes) that control chromatin modelling and transcriptional regulation. This is considered to extend the potential of the genetic code.

histone deacetylase *abbr.* HDAC; an enzyme that catalyses the hydrolysis of acetyl groups from histones, and thereby regulates DNA-protein interactions. Histone deacetylases are part of transcriptional corepressor complexes. Inhibitors of histone deacetylases induce hyperacetylation of histones that modulate chromatin structure and gene expression, and induce growth arrest, cell differentiation, and apoptosis of tumor cells.

histone fold the interaction motif involved in homodimerization of the core histones (H2A and H2B, H3 and H4) and their assembly into an octomer. It comprises three alpha helices linked by two loops. The surface residues mediate octomer formation and interaction with the DNA that wraps around the octomer. The fold also

occurs in many transcription factors and in the chromatin accessibility complex (**CHRAC**).

histone modification the post-translational enzymatic modification of the N-terminal region of the core histones H2A, H2B, H3, and H4 by acetylation, methylation, phosphorylation, or ubiquitination. The extent and pattern of modification regulates chromosome condensation and is the basis of the **histone code** and the **nucleosome code**.

hit-and-run mutagenesis a form of mutagenesis by homologous recombination in mammalian cells in which a vector carrying the mutated homologous DNA sequence is inserted into the gene of interest thereby duplicating part of it. In a second step, intrachromosomal recombination between the native and homologous mutated sequences results in introduction of the mutation at the desired location.

hitchhiking 1 a *jargon term* for the sequence of events in which a genetic element (or **transposon**) inserts into an active secondary site on a replicon, which is then transferred to a recipient, the transposon then coming immediately to occupy its normal primary site in the DNA of the recipient organism. **2** the spread of a neutral allele through a population due to its linkage with a beneficial allele that is subject to selection.

HIV *abbr. for* human immunodeficiency virus; a **retrovirus**, the causative agent of **AIDS**. HIV-1 is found worldwide; HIV-2 is found mainly in West Africa. The gene structures of the **viral envelope sequences** (*see* **HIV protein**) of HIV-1 and HIV-2 are not closely related. HIV-2 is closely related to a **simian immunodeficiency virus** (SIV) common in sooty mangabeys and probably originated there. HIV-1, which probably originated from a non-human primate in Africa, is closely related to SIV from chimpanzees. However, it is not clear that chimpanzees represent the natural host of these viruses. The reverse transcriptase enzyme of HIV is highly error-prone, leading to a high mutation rate. Thus these viruses evolve very quickly even within single patients, and drug-resistant mutations appear rapidly. For HIV-1 to enter its target cells, it must bind to the cell-surface protein **CD4** and to one or more chemokine receptors. One of these, named **CCR5**, is effective in the early stages of infection. Patients with defective CCR5 cannot be infected with HIV-1. During the later stages of infection, another chemokine receptor, **CXCR4** (*former name:* fusin) dominates.

HIV entry cofactor an *alternative term* for **fusin**.

HIV-1 protease an aspartyl protease that is a homodimer of two subunits each containing 99 amino acids, with cysteines at positions 67 and 95. Its proteolytic function is essential for the life cycle of human immunodeficiency virus (HIV) and is, therefore, a target for the design of inhibitors as therapeutic drugs, several examples of which are in use.

HIV protein any of the proteins encoded by the human immunodeficiency virus (HIV). The HIV-1 genome (9.5 kb) is transcribed to give 12 different mRNAs, generated by alternative splicing. The proteins are conventionally named for the gene and/or their size (kDa), with the convention that p = protein and gp = glycoprotein. The primary translation products are: Gag precursor (p53); Pol precursor; Env precursor (gp160); Nef (p27; negative regulator); Vif (p23); Tat (p14; regulatory protein); Rev (p19; regulatory protein); Vpr (p18); and Vpu (p15). The Gag precursor is cleaved to myristoylated Gag protein (p17), structural protein (p24), and p15; p15 is the precursor for RNA-binding protein (p7) and proline-rich protein (p9). The Pol precursor is cleaved to protease (p10), reverse transcriptase (p51), and endonuclease (p32). The Env precursor is cleaved to extracellular protein (gp120) and transmembrane protein (gp41). Protease, reverse transcriptase, and endonuclease are synthesized as part of a polyprotein. *See also* **retrovirus**.

HK *abbr. for* **histidine kinase**.

HKD catalytic motif *see* **PhD enzyme**.

HL-60 a continuous line of promyelocytic cells that can be made to differentiate into macrophage-like cells by treatment with the phorbol ester TPA or into granulocytes by treatment with dimethylsulfoxide (DMSO) or all-*trans* retinoic acid.

HLA *abbr. for* human leukocyte-associated antigen. *See also* **histocompatibility antigen, major histocompatibility complex.**

HLA histocompatibility system a family of histocompatibility

antigens encoded by the complex of genetic loci known as the **major histocompatibility complex** (MHC). It is the major histocompatibility system in humans, equivalent to the H-2 histocompatibility system in mice. The MHC genes control the presence of HLA **isoantigens** on cell surfaces. These antigens are of primary importance in tissue grafting since HLA-incompatible grafts are more likely to be rejected than incompatible grafts of other isoantigen groups.

HLH *abbr.* for helix-loop-helix (*see* **helix-turn-helix**).

hly genes *see* **hemolysin**.

HMC *abbr.* for 5-hydroxymethylcytosine.

H-meromyosin *abbr.* for heavy meromyosin.

HMG or **HMG** *abbr.* for human menopausal gonadotropin (i.e. human urogonadotropin).

HMG 1 *abbr.* for 2-hydroxy-2-methylglutaryl. **2** *abbr.* for high mobility group of nuclear proteins. **3** *see* **HMG**.

HMG-CoA *abbr.* for hydroxymethylglutaryl-CoA.

HMG-CoA lyase *abbr.* for hydroxymethylglutaryl-CoA lyase.

HMG-CoA reductase *abbr.* for hydroxymethylglutaryl-CoA reductase.

HMG-CoA synthase *abbr.* for hydroxymethylglutaryl-CoA synthase.

HMM *abbr.* for **1** heavy meromyosin. **2** hidden Markov model.

HMM *abbr.* for hydroxymethoxymandelate.

HMP *abbr.* for hexose monophosphate.

HMP pathway or **HMP shunt** *abbr.* for hexose monophosphate pathway (shunt) (i.e. **pentose phosphate pathway**).

HNF *abbr.* for hepatocyte nuclear factor.

HNPCC *abbr.* for hereditary nonpolyposis colon cancer; an autosomal dominant disease associated with mutations in several genes encoding proteins (e.g. MutL, MutS, GTBP) that may normally take part in mismatch repair of DNA.

hnRNA or **HnRNA** *abbr.* for heterogeneous nuclear RNA (alternatives to H-RNA).

hnRNP *abbr.* for heterogeneous nuclear ribonucleoprotein.

hnRNP particles *abbr.* for heterogeneous nuclear ribonucleoprotein particles; particles in the nucleus containing **hnRNA** bound to protein.

H-NS basic DNA-binding proteins of several bacterial families, characterized by an N-terminal tetrapeptide, consensus Ser-Glu-Xaa-Leu. Although their precise role remains unclear, they may be the prokaryotic counterparts of **histones** in eukaryotic chromatin. They have the ability to bind to curved DNA, and may have a role in transcriptional regulation. The name derives from an isolation procedure extracting them from the 30S ribosomal native subunit.

Ho *symbol* for holmium.

HO *abbr.* for heme oxygenase.

Hoechst 33342 *see* **bisbenzimidazole**.

Hoechst 33258 a bis-benzimidazole fluorescent dye used for measuring DNA concentration. *See* **bisbenzimidazole**.

Hoff *see* **van't Hoff**.

Hofmeister series or **lyotropic series** an arrangement of either the simple anions or the simple cations (or of the salts of such ions) in order of their ability to remove lyophilic substances from colloidal solutions. Each series is an index of, *inter alia*, the relative abilities of the ions to salt-out proteins from solution. The order for anions is: citrate³⁻ > tartrate²⁻ > acetate⁻ > NO₃⁻ > ClO₄⁻ > CNS⁻, and that for cations is: Mg²⁺ > Ca²⁺ > Sr²⁺ > Ba²⁺ > Li⁺ > Na⁺ > K⁺ > Rb⁺ > Cs⁺. [After Franz Hofmeister (1850–1922).]

Hofstee plot *see* **Eadie-Hofstee plot**.

Hogness box *an alternative name* for **TATA box**.

hol+ *a variant form of* (before a vowel) **holo+**.

holandric inherited solely in the male line. *Compare* **hologynic**.

holdback agent or **holdback carrier** any nonradioactive substance that is added to a sample to prevent either coprecipitation or adsorption of some soluble radioactive substance.

hold-up volume *symbol:* V_M ; (*in chromatography*) the volume of eluent required to elute a component whose concentration in the stationary phase is negligible relative to that in the mobile phase. In gas chromatography, the volume of carrier gas (eluent) is specified at the same temperature and pressure as the total retention volume.

hole (*in physics*) the absence of an electron in a normally filled val-

ency structure of a crystalline **semiconductor** that behaves as a carrier of charge and is mathematically equivalent to a positron.

holin a protein encoded by dsDNA bacteriophages that permeabilizes the plasma membrane of host cells to permit exit of the enzyme **endolysin** that degrades the murein matrix to enable the release of progeny phage. Holins constitute a subclass of transport proteins of the TC system, designated 1.E. They contain between 45 (TC 1.E.6) and 250 (TC 1.E.8) amino acid residues.

Holliday junction or **Holliday structure** one of the junctions between four strands of DNA that are important intermediates in **genetic recombination**. They are part of the mechanism for **crossing over** during the long prophase of meiotic cell division I, when four strands of DNA are aligned. The process involves breaking the DNA double helix in a maternal chromatid and in a homologous paternal chromatid and then exchanging fragments between the two non-sister chromatids in a reciprocal fashion. At this point, in each four strands, a paternal strand links across to a maternal strand, forming the junction known by the name of its proposer. [After Robin Holliday (1932–), British biologist.]

hollow-cathode discharge lamp a radiation source used in **atomic absorption spectrophotometry** to produce a spectrum of radiation specific to the element being assayed. A sample of the element in question is held in a metal cup-shaped cathode, which, together with a tungsten anode, is enclosed in a glass or quartz envelope filled with argon at low pressure. A high voltage is used to produce an arc spectrum of the element.

hollow-fibre technique a technique in which bundles of semipermeable, hollow fibres with pores of controlled dimensions that function as molecular sieves are used for concentrating, desalting, dialysing, and fractionating macromolecules in solution. *Compare* **capillary filtration**.

holo+ or (*before a vowel*) **hol+** *comb. form* whole, entire, complete; wholly, entirely, completely.

holocarboxylase synthetase an enzyme that biotinylates the ϵ -amino group of lysine residues to form **biocytin** at the active site of biotin carboxylases (*see* **acetyl-CoA carboxylase**). In humans, numerous mutations of the gene at 21q22.1 (which encodes 726 residues) are associated with neonatal multiple carboxylase deficiency, which is clinically similar to biotinidase deficiency.

holocellulose the complex mixture of polysaccharides remaining after the removal of lignin from tree-wood by treatment with sodium chlorite solution. It consists of a mixture of **cellulose** and **hemicellulose**.

holocrine 1 describing a type of secretion that involves disintegration of the entire secretory cell to release the secretory products. **2** describing a gland made up of such cells. *Compare* **apocrine**, **eccrine**, **merocrine**.

holoenzyme a catalytically active complex comprising the protein part of an enzyme (**apoenzyme**) combined with the appropriate cofactor or cofactors.

hologram 1 the pattern produced when light, or other electromagnetic radiation, that has been reflected, diffracted, or transmitted by an object placed in a coherent beam, interferes with a reference beam related in phase to the first beam. **2** a photograph of such a pattern.

hologram 1 to make a **hologram** (def. 1, 2). **2** any book or other document handwritten by its author.

holography the process of making and using **holograms** (def. 1, 2). —*holographic* *adj.*

hologynic inherited solely in the female line. *Compare* **holandric**.

Holometabola or **Endopterygota** one of the two divisions of the subclass Pterygota, comprising those insects, e.g. butterflies, moths, flies, and beetles, in which the juvenile forms (larvae) are very different from the adults. Such insects undergo complete metamorphosis during a resting stage (pupa). *Compare* **Hemimetabola**.

holoprosencephaly *see* **hedgehog protein**.

holoprotein the functional form of a protein containing a protein part (**apoprotein**) together with any appropriate ligand or ligands.

holorepressor a functional repressor protein consisting of an **aporepressor** plus **corepressor** complex.

homeo+ or **homoeo+** or **homoio+** *comb. form* denoting like or similar.

homeobox a short (180 bp) conserved DNA sequence that encodes a DNA-binding motif famous for its presence in genes that are involved in orchestrating the development of a wide range of organisms. *See also* **homeotic gene**.

homeodomain the DNA-binding motif of 60 amino acids encoded by a **homeobox**.

homeomorphism or **homoeomorphism** (*in chemistry*) the property shown by certain substances of having the same crystal form but different compositions. —**homeomorphic**, **homeomorphous**, or **homoeomorphic**, **homoeomorphous** *adj.*

homeostasis or **homoeostasis** the maintenance of a relatively constant internal environment in the bodies of higher animals by means of a series of interacting physiological and biochemical processes. —**homeostatic** or **homoeostatic** *adj.*

homeotic gene or **homeodomain-encoding gene** or **homeobox-encoding gene** or **Hox gene** any of the genes that are allelic for mutations resulting in the conversion of one body part into another. Homeotic genes were first discovered in *Drosophila*; a mutation in such a gene could, e.g., result in a leg replacing an antenna. While *Drosophila* has only two *Hox* clusters, in nematodes there is one, and in vertebrates four clusters of 9 to 11 genes each located on a separate chromosome and spanning more than 100 kb. The vertebrate *Hox* genes are expressed in specific patterns and at particular stages in embryogenesis. They are activated by **retinoic acid** and **sonic hedgehog protein**. In the limb these are active in concert with **fibroblast growth factor**. The homeobox portion of the *Hox* genes in different species is remarkably conserved. The structure of some homeodomains has been determined, as has their interaction with DNA.

homeothermic *the usual US spelling of homiothermic.*

homeotic selector any of a family of genes in *Drosophila* that select the expression of **homeotic genes**. They encode homologous regulatory proteins that contain a **homeobox** sequence.

homeotypic pertaining to, or being the second, reductive division in **meiosis**. *Compare* **heterotypic**.

Homer any protein belonging to a family whose members have an N-terminal EVH1 homology sequence that interacts with a proline-rich sequence motif (called Homer ligand), which is present in some metabotropic glutamate receptors (mGluRs) and on the cytosolic region of the inositol trisphosphate (IP₃) receptor. It also contains a C-terminal coiled-coil region for homodimer formation. Homer helps localize mGluRs to synapses and mediates their effects on IP₃ receptors.

Homer ligand *see* **Homer**.

homo+ *comb. form* **1** the same, similar, alike. *Compare* **allo+** (def. 1); **hetero+** (def. 1); **iso+** (def. 1); **xeno+** (def. 1). **2** from, or directed towards, the same species. *Compare* **allo+** (def. 2); **hetero+** (def. 2); **iso+** (def. 2); **xeno+** (def. 2). **3** containing atoms, groups, linkages, residues, or subunits of the same kind. *Compare* **hetero+** (def. 3). **4** denoting the next higher homologue of a specified chemical compound, especially one whose molecules contain, in a hydrocarbon chain or ring, one more methylene, $-\text{CH}_2-$, than those of of the parent compound, e.g. homocysteine, homoserine, homo-5 α -pregnane. *Compare* **nor+** (def. 2).

Homo a genus of primates that includes modern man (*Homo sapiens*) and a number of more primitive, fossil species.

homoarginine (*sometimes*) a trivial name for *N*⁶-amidino lysine.

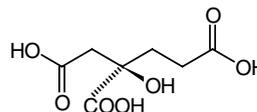

hombifunctional describing a chemical reagent that carries two identical reactive groups. *Compare* **heterobifunctional**.

homocarnosine (*sometimes*) a trivial name for *N*^ε-(4-aminobutyl)histidine. It is present in brain but its function is unclear.

homochromatic a less common term for **monochromatic** (def. 1).

homochromatography a chromatographic technique for the separation of labelled oligonucleotides, in which a mixture of unlabelled oligonucleotides is used to displace the labelled components according to differences in size.

homocitrate 2-hydroxybutane-1,2,4-tricarboxylate; the (*R*) enantiomer is a component of the **aminoadipic pathway** and is formed by **homocitrate synthase**.

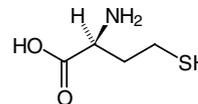

homocitrate synthase EC 4.1.3.21; *systematic name*: 2-hydroxybutane-1,2,4-tricarboxylate 2-oxoglutarate-lyase (CoA-acetylating). An enzyme that catalyses the formation of **homocitrate** from 2-oxoglutarate and acetyl-CoA and H₂O. *See also* **aminoadipic pathway**.

homoconjugation the association between a base and its conjugate acid through a hydrogen bond. *See* **conjugate acid–base pair**. *Compare* **heteroconjugation**.

homocyclic 1 describing any cyclic molecular structure containing atoms of a single element in the ring or rings; describing any compound having such a structure. The term is preferred to its synonym **isocyclic**; it includes **carbocyclic** (def. 1). *Compare* **heterocyclic** (def. 1). **2** any such compound.

homocysteine *symbol*: Hcy; α -amino- γ -mercaptobutyric acid; 2-amino-4-mercaptobutanoic acid; an important intermediate in the metabolic reactions of its *S*-methyl derivative, methionine. Its concentration in human serum is raised after stroke.

L-homocysteine

homocysteine methyltransferase one of several enzymes, e.g. the two alternative forms of enzyme synthesizing methionine: (1) 5-methyltetrahydrofolate–homocysteine *S*-methyltransferase. (EC 2.1.1.13); *other name*: tetrahydropteroylglutamate methyltransferase; it catalyses a reaction between 5-methyltetrahydrofolate and L-homocysteine to form tetrahydrofolate and L-methionine; cobalamin is a cofactor. (2) 5-methyltetrahydropteroyltriglutamate–homocysteine *S*-methyltransferase (EC 2.1.1.14); *other name*: tetrahydropteroyltriglutamate methyltransferase; it catalyses a reaction between 5-methyltetrahydropteroyltri-L-glutamate and L-homocysteine to form tetrahydropteroyltri-L-glutamate and L-methionine.

homocystine 2,2'-diamino-4,4'-dithiobis(butanoic acid); the disulfide oxidation product of **homocysteine**.

homocystinemia or (*esp. Brit.*) **homocystinaemia** a usually inherited biochemical abnormality of humans, characterized by an abnormally high concentration of homocystine in the blood and in the urine (**homocystinuria**). The condition may be due to: (1) a deficiency of cystathionine β -synthase (EC 4.2.1.22) activity; (2) a deficiency of methylene tetrahydrofolate reductase; or (3) a deficiency of cobalamin. Homocystinemia is an independent risk factor for thromboembolic events.

homodetic describing a cyclic peptide in which the ring consists solely of amino-acid residues in eueptide linkage. *Compare* **heterodetic**.

homodimer any macromolecular structure in which two identical subunits (monomers or protomers) are noncovalently associated. *See also* **dimer**. *Compare* **heterodimer**.

homoduplex hybrid DNA involving two strands that are complementary. *Compare* **heteroduplex**.

homoeo+ a variant form of **homeo+**.

homogametic describing the sex whose cell nuclei contain a pair of similar **sex chromosomes**. The homogametic sex is usually female, but is male in the Lepidoptera, birds, some amphibians and fishes, and a few plants. *Compare* **heterogametic**.

homogenate any disrupted tissue preparation in which cell disruption

tion is maximal while the destruction of intracellular organelles is kept to the minimum.

homogeneous an alternative term for **allogeneic**. Compare **heterogeneous**.

homogeneous 1 being uniform in kind, as in a homogeneous population. **2** (*describing a group of molecules*) uniform in structure or composition. **3** (*describing a system*) consisting of only a single chemical phase. Compare **heterogeneous**, **homogenous**. —**homogeneity** *n*.

homogeneous catalysis any catalytic action or process in which the catalyst is uniformly distributed in the same chemical phase as the reactants. Compare **heterogeneous catalysis**.

homogeneous enzyme immunoassay or **enzyme-multiplied immunoassay technique** (*abbr.*: EMIT) a technique of **homogeneous immunoassay** in which an enzyme is covalently coupled to the substance to be assayed. The enzymic activity of the complex is inhibited by an antiserum specific for the substance and this inhibition is relieved by the presence of free molecules of the substance to be assayed. The enzyme acts as a molecular amplifier.

homogeneous immunoassay any immunoassay that does not involve physical separation of antibody-bound antigen from antigen molecules that remain free. Labels that may be attached to the antigen include: enzymes, cofactors, prosthetic groups or substrates of enzymes, chemiluminescent or fluorescent molecules, stable free radicals. Compare **heterogeneous immunoassay**.

homogeneously staining region a region in a chromosome that stains homogeneously, rather than with the banding pattern normally seen. The region contains massively amplified numbers of copies of a small segment of the genome. The amplified DNA may often consist of multidrug resistance gene DNA (*see* **MDR**).

homogenesis the production of offspring having the same characteristics in successive generations. Compare **heterogenesis**.

homogenetic describing chromosome pairing during meiosis when the pairing partners are derived from one of the original ancestors. Compare **heterogenetic**.

homogenic or **congenic 1** describing a gamete that contains only one allele of a particular gene. **2** describing two genetic elements that are descended from a common ancestor by a known sequence of steps. **3** an alternative word for **homogeneous**. Compare **heterogenic**.

homogenize or **homogenise** produce a **homogenate**. —**homogenization** or **homogenisation** *n*.

homogenizer or **homogeniser** any apparatus for producing a **homogenate**.

homogenous 1 of, pertaining to, or exhibiting **homogeny**. **2** an alternative word for **homogeneous**.

homogentisate or (*formerly*) **alcapton** 2,5-dihydroxyphenylacetate; an intermediate in the catabolism of tyrosine and in the biosynthesis of plastoquinone and tocopherol. It is excreted in abnormally large quantities in the urine in **alcaptonuria**. *See also* **homogentisate 1,2-dioxygenase**.

homogentisate 1,2-dioxygenase EC 1.13.11.5; *systematic name*: homogentisate:oxygen 1,2-oxidoreductase (decyclizing); *other names*: homogentisicase; homogentisate oxygenase; homogentisic acid oxidase. An enzyme with highest activity in liver that catalyses the oxidation by dioxygen of homogentisate to 4-maleylacetoacetate; iron(II) is a cofactor. In the catabolism of L-tyrosine, **homogentisate** is formed from 4-hydroxyphenylpyruvate; maleylacetoacetate is converted to fumarylacetoacetate, which is split to fumarate and acetoacetate. Mutations in the gene result in enzyme deficiency and the rare metabolic disorder alcaptonuria.

homogeny (*in biology*) similarity in the structure of organisms or parts of organisms because of common ancestry.

homoglycan or **homopolysaccharide** any polysaccharide (i.e. glycan) that contains residues of only one kind of monosaccharide (i.e. glucose) molecule. Compare **heteroglycan**.

homograft an old term for **allograft**. Compare **heterograft**.

homoio+ a variant form of **homeo+**.

homoiosmotic describing organisms with a constant internal osmotic pressure. Compare **poikilosmotic**.

homoiothermic or **homoiothermal** or (*esp. US*) **homeothermic** or **homeothermal** describing an organism (**homoiotherm**) that sustains a relatively constant body temperature, usually higher than that of its

surroundings. Compare **poikilothermic**. —**homoiothermy** or (*esp. US*) **homeothermy** *n*.

homokaryon or **homocaryon** any cell with more than one nucleus, and in which the nuclei are all of the same genetic constitution; a tissue composed of such cells. Compare **heterokaryon**. —**homokaryotic** or **homocaryotic** *adj*.

homokaryosis or **homocaryosis** the condition of having a **homokaryon** or **homocaryons**. Compare **heterokaryosis**.

homolactic fermentation a type of fermentation of glucose to lactate via the Embden–Meyerhof pathway. Compare **heterolactic fermentation**.

homolog (*sometimes*) the US spelling of **homologue**.

homologous 1 having a related or similar position, structure, etc.; corresponding; exhibiting **homology**. **2** (*in chemistry*) describing compounds that form a series with successive constant differences in composition. **3** (*in biology*) of common ancestry; especially of organs and tissues that have a similar anatomical position and structure in different species by virtue of their common evolutionary origin, even though their functions may have come to differ; e.g. the wing of a bird and the forelimb of a reptile. Compare **analogous**. **4** (*in genetics*) describing chromosomes that pair during meiosis, each member of a homologous pair being a duplicate of one of the chromosomes contributed at syngamy by the mother or the father. **5** (*in biochemistry*) **a** (of sequences of residues in encoded macromolecules) having the same or similar residues at corresponding positions (*see also* **conserved**). With respect to proteins the term is used to imply a common evolutionary origin. Specifically this requires evidence based on gene structure and not merely a similarity of protein structure. **b** (of proteins from different species) having identical or similar functions. Compare **heterologous**. —**homology** *n*.

homologous antibody the antibody elicited by a specified antigen. **homologous antigen** the antigen that has elicited a specified antibody.

homologous desensitization *see* **desensitization**.

homologous recombination **genetic recombination** between two DNA molecules of identical or nearly identical sequence when contained in the same cell. It occurs naturally during meiosis, and is exploited when performing gene knockouts in yeast, embryonic stem cells, and other cells.

homologue or (*sometimes*) **US homolog 1** (something) exhibiting homology. **2** (*in chemistry*) any member of a **homologous** (def. 2) series of compounds. **3** (*in biology*) any one of a series of **homologous** (def. 3) organs or structures. **4** (*in genetics*) **a** either members of a pair of **homologous** (def. 4) chromosomes. **b** either one of two genes in corresponding loci in homologous chromosomes. **5** (*in sequence analysis*) any of two or more nucleotide or protein sequences that are evolutionarily related to each other by descent from a common ancestor. Homologous sequences may be orthologues or paralogues.

homology domain any of the regions in an immunoglobulin involved in forming the **immunoglobulin fold**.

homology modelling a computational method for predicting protein structure based on similarity to a sequence of known structure. The accuracy of homology-derived models depends on the level of similarity between the target and model sequences, and hence on the quality of their alignment: the greater the similarity, the better the alignment and the better the model is likely to be. The resolution of structures modelled in this way is generally low.

homolysis (*in chemistry*) the cleavage of a covalent bond in such a manner that each of the fragments between which the bond is broken retains one of the bonding electrons; e.g. A–B → A• + B•. —**homolytic** *adj*.

homooligomer any **oligomer** made up of only one kind of constitutional repeating unit. —**homooligomeric** *adj*.

homophilic binding (*of adhesion molecules*) binding of an adhesion molecule in one cell to an identical molecule in an adjacent cell. Compare **heterophilic binding**.

homoplasy (*in phylogeny*) the occurrence of similar characters, independently of lineage, via parallel or convergent evolution (sometimes these processes are distinguished, sometimes the difference is considered irrelevant) or reversion. Such characters cannot therefore be used to construct phylogenetic trees.

homopolymer any polymer made up of only one kind of constitutional repeating unit. For example, cellulose contains only glucose as the monomeric unit. —**homopolymeric** *adj.*

homopolymer tailing a *jargon term* for a procedure useful in joining two types of duplex DNA molecules to form mixed dimeric circular DNA. In this procedure, homopolymer sequences of one type, e.g. poly(dA), are added to the 3'-ends of one of the populations of DNA molecules, while complementary homopolymer sequences, e.g. poly(dT), are added to the 3'-ends of the other population of DNA molecules. The two types of molecules are then annealed to form mixed dimeric circles.

homopolysaccharide an alternative name for **homoglycan**.

homoserine *symbol:* Hse; α -amino- γ -hydroxybutyric acid; an intermediate in the biosynthesis of cystathionine, threonine, and methionine. It also occurs in bacterial peptidoglycans and, as its *O*-guanidino derivative, in canavanine. The term normally implies the L enantiomer.

homoserine deaminase *see* **cystathionine γ -lyase**.

homoserine dehydratase *see* **cystathionine γ -lyase**.

homoserine dehydrogenase EC 1.1.1.3; *systematic name:* L-homoserine:NAD(P)⁺ oxidoreductase; an enzyme of methionine and threonine biosynthesis. It catalyses the formation of L-homoserine and NAD(P)⁺ from L-aspartate 4-semialdehyde and NAD(P)H. *Escherichia coli* has a homotetrameric bifunctional enzyme consisting of 820 amino acids. Residues 1–249 form the aspartokinase I domain, 250–470 form a large 'interface', and 471–820 form homoserine dehydrogenase; regulation is by L-Thr. *See also* **aspartokinase/homoserine dehydrogenase**.

homoserine lactone *symbol:* Hsl; α -amino- γ -butyrolactone; a substance formed by the cleavage of methionine-containing peptides by cyanogen bromide.

homosterism or **homostery** the phenomenon in which a second molecule of normal substrate, or a structurally similar compound, combines at the catalytic site of an enzyme leading to a modification in the reaction of the bound intermediate. *Compare* **allosterism**. —**homosteric** *adj.*

homostery an alternative term for **homosterism**.

homothallic describing species, e.g. of certain fungi and algae, in which a sexual spore can result from the fusion of nuclei that are genetically distinct (i.e. not necessarily homozygous), but are derived from the same thallus; thus the species is self-fertile.

homothallic switching endonuclease a sequence-specific endonuclease, with a site on yeast chromosome III, that is involved in mating-type switching. It is a **zinc finger** protein.

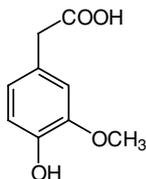

homotherm an alternative word for **homiotherm**.

homotope any residue that can take the place of another residue in a particular position in a polymer; e.g., the serine and glycine residues at position 9 of the A chain of bovine and ovine insulin, respectively, are homotopes.

homotransplant 1 an alternative term for **homograft**. **2** to effect such a transplant.

homotropic describing an **allosteric** effect in which interaction occurs between identical ligands; the effect appears to be always cooperative. The term is applied also to such an interaction in the case of an allosteric enzyme for which the same substance acts as both the substrate and the allosteric effector, etc. *Compare* **heterotropic** (def. 1).

homovanillic acid *abbr.:* HVA; 4-hydroxy-3-methoxyphenylacetic acid; a metabolite of catecholamine metabolism, found in human urine. It is the principal urinary metabolite of dopa and dopamine. It is used as a reagent in the fluorometric determination of glucose oxidase and other oxidases.

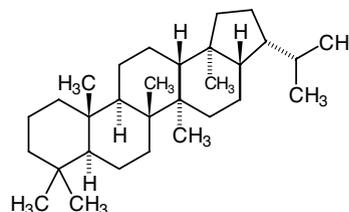

homozygosis 1 the union of gametes identical for one or more pairs of genes to form a **homozygote**. **2** or **homozygosity** the state or condition of being a homozygote. *Compare* **heterozygosis**.

homozygosity an alternative term for **homozygosis** (def. 2).

homozygote any cell or organism having identical genes (alleles) at one or more corresponding loci on homologous chromosomes. With respect to such loci, a homozygote will produce two identical gametes. *Compare* **heterozygote**. — **homozygotic** or **homozygous** *adj.*

Hoogsteen base pair a nucleic-acid base pair that differs from the Watson-Crick base pair. In the Hoogsteen adenine–thymine base pair the 6-NH₂ and N-7 of the adenine are hydrogen bonded respectively to the 4-O and H-1 of the thymine. The Hoogsteen guanine–cytosine pair requires that N-1 of the cytosine is protonated. In this base pair the 6-O and N-7 of the guanine are hydrogen bonded respectively to the 4-NH₂ and the protonated N-1 of cytosine. In Watson–Crick base pairs the glycosidic bond of both nucleotides has the *anti* conformation, but in the Hoogsteen pairs the glycosidic bond of the purine nucleotide has the *syn* conformation. Hoogsteen base pairs are particularly important in the structure of DNA triple helices, where the third strand forms Hoogsteen pairs to bases in the DNA duplex. [After Karst Hoogsteen (1923–), Dutch–American biochemist, who first described it.]

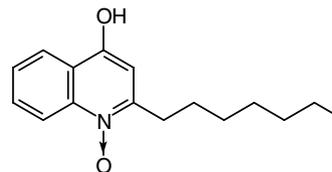

hopane the pentacyclic triterpene hydrocarbon parent of hopanone and derivatives found in plant resins. *See also* **hopanoids**.

hopanoids pentacyclic sterol-like molecules based on the **hopane** nucleus. They are found in bacteria, some plants and lichens, and in sediments and crude oils, and are said to be the most abundant organic molecules in the biosphere (estimated total biomass 10¹¹ to 10¹² tonnes), thus outranking **cellulose**.

Hopkins–Cole reaction a colour reaction for free or combined tryptophan, in which a violet colour is produced when a solution containing tryptophan is treated with glyoxylic acid (present in impure glacial acetic acid) and subsequently layered onto a solution of pure, concentrated sulfuric acid. [After (Sir) Frederick Gowland Hopkins (1861–1947), British biochemist, and Sydney William Cole (1877–1951).]

HQNO or **HQNO** *abbr. for* 2-*n*-heptyl-4-hydroxyquinoline *N*-oxide; an inhibitor of the mitochondrial respiratory chain at cytochrome *b_c* and of photosynthetic electron flow immediately before cytochrome *b₅₅₉*LP.

hordein a type of **glutelin** found in barley.

horizontal gene transfer the transfer of genes from one organism to another (as distinct from vertical gene transfer, i.e. from parent to offspring).

hormone any substance formed in very small amounts in one specialized organ or group of cells and carried (sometimes in the bloodstream) to another organ or group of cells, in the same organism, upon which it has a specific regulatory action; an **endocrine** (def. 2). The term was originally applied to agents with a stimula-

tory physiological action in vertebrate animals (as opposed to a **chalone**, which has a depressant action). Usage is now extended to regulatory compounds in lower animals and plants, and to synthetic substances having comparable effects. *Compare autacoid, hormone. See also secretin. —hormonal adj.*

hormone cascade *see cascade sequence.*

hormone receptor any protein of the plasma membrane, or present intracellularly, that binds a hormone and mediates its physiological effects. Hydrophilic hormones (i.e. those that are proteins, peptides, or other amino acid derivatives) are ligands of plasma membrane receptors, which modulate the activity of intracellular intermediaries. Hydrophobic hormones (e.g. steroids, thyroid hormones, vitamin D derivatives) are ligands of cytosolic or nuclear receptors, which modulate the activity of responsive genes by binding to their **hormone response elements**. Examples include the **glucocorticoid receptor** and **insulin receptor**.

hormone resistance the state of decreased or absent sensitivity to a hormone. It may be primary and due to a defect in a specific receptor (e.g. for glucocorticoids, androgens, estrogens, vitamin D derivatives, thyroid hormones, thyroid stimulating hormone, parathyroid hormone, antidiuretic hormone, insulin) or due to post-receptor defects (e.g. in diabetes mellitus type 2). Acquired resistance may result from damage to a target tissue, in the course of therapy with the hormone, or by immunological mechanisms.

hormone response element *abbr.*: HRE; a specific nucleotide sequence in the promoter region of a structural gene that binds to the DNA-binding domain of a nuclear hormone receptor. The HRE usually consists of two hexanucleotide sequences that are contiguous or separated by three nucleotides, and may be in tandem or in palindromic arrangement.

hormone-sensitive lipase any enzyme of the sub-subclass EC 3.1.1 that, when activated in adipose tissue, catalyses the mobilization of fatty acids into the circulation. Such enzymes are activated by cyclic AMP-dependent phosphorylation under the influence of catecholamines, and are inactivated by insulin-dependent dephosphorylation.

hormonotoxin any conjugate of a peptide hormone and a peptide toxin, e.g. ovine luteinizing hormone–goneloin.

horse radish peroxidase *abbr.*: HRP; a hemoprotein enzyme that is widely used to label antibodies and other proteins in enzyme immunoassays and related procedures such as immunodetection following Western blotting.

host 1 any organism in which another organism, especially a **parasite** or **symbiont**, spends part or all of its life cycle and from which it obtains nourishment and/or protection. **2** any organism that harbours a pathogenic or nonpathogenic infectious agent. **3** the recipient of a transplanted tissue or organ graft. **4** a cell or organism that contains recombinant DNA.

host cell any cell whose metabolism is used for the growth and reproduction of a virus.

host-cell reactivation *abbr.*: HCR; the restoration of activity in a UV-damaged DNA bacteriophage by the excision-repair mechanisms of the host cell in which it multiplies.

host-controlled modification or **host-controlled variation** or **host-induced modification** or **host-induced variation** any nonheritable change in the properties of a DNA bacteriophage resulting from the phage DNA assuming the DNA **modification** pattern characteristic of the host bacterium. It is usually recognized by **restriction** in the efficiency of plating of the newly modified phage on its former host strain. Similar phenomena have been described for viruses infecting eukaryotic cells.

host-induced modification or **host-induced variation** *see host-controlled modification.*

host-guest chemistry a branch of chemistry in which a larger and structurally concave organic molecule (the host) selectively binds to a smaller molecule or ion (the guest). This may mimic a biological effect, or prevent a biological interaction.

host range the spectrum of host organisms that can be infected by a specified infectious agent or parasite.

host-vector system a compatible combination of host and **vector** (def. **3**) that allows propagation of DNA.

hot (*in physics*) an *informal term* describing a substance or material

that contains a radionuclide, especially if **carrier-free** or at a dangerously high activity or specific activity. *Compare cold.*

hot laboratory or **hot lab** an *informal term* for a laboratory reserved and equipped for the manipulation of radioactive substances or materials of (dangerously) high activity.

hot room 1 a room (or laboratory) maintained at a constant, higher-than-ambient temperature. **2** an *informal term* for a room (or laboratory) that is specially equipped to deal with high levels of radioactivity.

hot spot any site at which mutations are observed with an unusually high frequency. Such sites have a highly enhanced, inherent susceptibility to mutation that cannot be ascribed to the type of base pair involved, the way in which it is altered, or the resulting change in any protein encoded by the DNA molecule.

hot start PCR a type of polymerase chain reaction (PCR) designed to minimize nonspecific amplification. Reagents are heated to a temperature that does not permit hybridization between oligonucleotides and the target sequence before the addition of a thermostable DNA polymerase to start the reaction.

hour *symbol*: h or hr; a non-SI unit of time equal to 3600 s.

housekeeping genes *see constitutive genes.*

Houssay animal a pancreatectomized animal which has also undergone **hypophysectomy**. The latter ameliorates the diabetic state that results from pancreatectomy by abolishing the secretion of **somatotropin**. [After Bernardo Alberto Houssay (1887–1971), Argentinian physiologist and endocrinologist.]

Hox gene *see homeotic gene.*

Hp 1 *symbol* for the heptyl group, $\text{CH}_3\text{---}[\text{CH}_2]_5\text{---CH}_2\text{---}$. **2** *abbr.* for haptoglobin.

HP-1 *abbr.* for helper peak-1 (now called **interleukin 1**).

HpaI a type 2 **restriction endonuclease**; recognition sequence: $\text{GTT}\uparrow\text{AAC}$.

HpaII a restriction endonuclease that cuts at the sequence CCGG when the first C is unmethylated. **MspI** is unaffected by methylation at this position. Comparison of restriction digests with both enzymes is informative about the methylation of DNA.

HPCE *abbr.* for high performance capillary electrophoresis.

HpETE *abbr.* for hydroperoxyeicosatetraenoate.

hPL or **HPL** *abbr.* for human placental lactogen.

HPLAC *abbr.* for high-performance liquid affinity chromatography.

HPLC *abbr.* for high-pressure liquid chromatography or high-performance liquid chromatography.

Hpo *symbol* for the heptanoyl group, $\text{CH}_3\text{---}[\text{CH}_2]_5\text{---CO---}$.

HPoDE *abbr.* for hydroperoxyoctadecadienoate.

HPR *abbr.* for H protein; a low- M_r , heat-stable, cytoplasmic phosphocarrier protein found in some bacterial species, and concerned in the phosphoenolpyruvate (PEP)-hexose transferase system for the transport of hexoses across the cell membrane. The phosphate of PEP is transferred transiently to HPR. *See enzyme 1, enzyme 11.*

HPRD *abbr.* for human protein reference database; *see pathway database.*

H protein *see glycine cleavage enzyme.*

HPRT *abbr.* for hypoxanthine phosphoribosyltransferase.

H⁺ pump *see hydrogen ion pump.*

HQNO *see HQNO.*

hr *abbr.* for hour (now superseded by h).

Hrb a Rab protein (*see RAB*) that is essential for formation of the acrosome of mouse spermatozoa. It is associated with the cytosolic surface of proacrosomic vesicles that fuse to create a single large acrosome, and is required for docking and/or fusion of these vesicles.

HRE *abbr.* for hormone response element.

H1, H2, H3 receptors *see histamine receptor.*

H-RNA *abbr.* for heterogeneous nuclear RNA (alternative to hnRNA or HnRNA).

HRP *abbr.* for horse radish peroxidase.

HRT *abbr.* for hybrid-released translation.

HSA *abbr.* for human serum albumin.

Hse *symbol* for a residue of the α -amino acid L-homoserine.

HSE *abbr.* for heat-shock regulatory element or heat-shock response element.

α_2 -HS-glycoprotein or **fetuin** an α -globulin found in fetal calf

serum, where it accounts for up to 45% of the total protein. It has a low isoelectric point and contains up to 35% carbohydrate, having three oligosaccharide chains, each of M_r 3400; it comprises various glycoproteins that differ in M_r . It is a growth factor for a variety of cell types; it also promotes endocytosis, possesses opsonic properties, and influences the mineral phase of bone. The amino-acid sequence has **cystatin** features; two peptides are cleaved from a precursor to form chains held together by a single disulfide bond.

Hsl *symbol* for a residue of the α -amino lactone L-homoserine lactone.

HSL *abbr.* for hormone-sensitive lipase.

hsp or **Hsp** *abbr.* for heat-shock protein.

HSP *abbr.* for **1** heat-shock protein. **2** high-scoring segment pair.

Hsp90 a highly conserved molecular chaperone. Other family members are Grp94/gp96 in the endoplasmic reticulum and HtpG in the prokaryotic cytosol. Unlike Hsp70, which promiscuously recognizes a large number of proteins, Hsp90 is characterized by the specific nature of its protein-protein associations. The majority of Hsp90 substrates (usually referred to as 'client' proteins) are involved in regulatory processes, the classical examples being signalling kinases and steroid hormone receptors. Maintenance of the biochemical activity of the clients is entirely dependent on continued interaction with Hsp90..

HSPG core protein *abbr.* for heparan sulfate proteoglycan core protein. *See also syndecan.*

HSSP *abbr.* for homology-derived secondary structure prediction; *see structure database.*

hst/KS *see KS/hst.*

H strand *abbr.* for heavy strand.

HSV *abbr.* for herpes simplex virus.

5-HT *abbr.* for 5-hydroxytryptamine (i.e. **serotonin**).

HTG *abbr.* for high-throughput genomic sequence.

HTH *abbr.* for helix-turn-helix.

HTLV *abbr.* for human T-cell lymphotropic virus; a **retrovirus** that causes a rare leukemia.

HTML *abbr.* for hypertext markup language; *see markup language.*

Htr either of two transmembrane proteins (HtrI or HtrII) that extend far into the cytoplasm of halobacteria and mediate phototaxis signalling from a sensory rhodopsin (SRI or SRII, respectively) to the flagellar motor.

H⁺-transporting ATP synthase EC 3.6.1.34; *systematic name:* ATP phosphohydrolase (H⁺-transporting); *other names:* H⁺-transporting ATPase; mitochondrial ATPase; chloroplast ATPase; coupling factors F₀F₁, C₀F₁. The enzyme that is responsible for the phosphorylation of ADP to ATP in mitochondria, during **oxidative phosphorylation**. *In vitro* it can function as an ATPase. The 3-D structure is known for the major components of bovine heart mitochondrial enzyme. The enzyme comprises an intrinsic membrane domain, F₀, linked by a stalk to a globular catalytic domain, F₁, and is hence sometimes termed the F₀F₁ complex. Energy released by hydron flux through F₀ leads to ATP synthesis by F₁; the stoichiometry is approximately 3H⁺ per ADP phosphorylated. F₁ (371 kDa) has the subunit composition: 3 α ,3 β , γ , δ , ϵ . The ϵ and γ subunits form a shaft inserted at one end into F₀ and at the other into F₁. The α and β (catalytic) subunits are arranged round it alternately; the three β subunits have different conformations during the synthesis cycle. The N- and C-terminal regions of γ form an antiparallel coiled coil; the α and β proteins are essentially beta barrels. There are several proteins in the F₀ component, the main subunits of which in eukaryotes are named A to G. Twelve C subunits form a channel within the membrane. The C chain is the protein that accumulates in ceroid lipofuscinosis (**Batten's disease**). It is a proteolipid encoded by two genes which code for two precursor proteins, P₁ and P₂, having different signal peptides for locating the proteins in mitochondria, but the same structure in the mature protein. Two B subunits are anchored, with an A subunit, into the membrane, and through a δ subunit bind F₁. The complex formed by AB₂ δ α β ₃ is called the stator; that formed by C₁₂ ϵ γ is called the rotor, because it rotates during the flow of hydrons through the F₀ channel.

H⁺-transporting pyrophosphatase an integral membrane protein (80 kDa) that contains 16 transmembrane segments and is

ubiquitous in vacuolar membranes in plants. It is also present in some species of archaea. In the presence of K⁺ it hydrolyses dimagnesium pyrophosphate of the cytosol and transports H⁺ into the vacuole. Ca²⁺ is a potent inhibitor, as is aminomethylenediphosphonate. In immature tissues it is more active than the V-type H⁺ ATPase, the opposite being true in mature tissues.

huangosome a colloquial term for a bilayered **liposome**. *Compare bangasome.*

Hudson's convention a convention, no longer used, for designating anomeric configurations in monosaccharides. The anomer in the D-series with the highest positive rotation (or lowest negative rotation) was designated the α form and the anomer with the lowest positive rotation was called the β form. The reverse applied in the L-series, the anomer with the lowest positive rotation (or the highest negative rotation) being designated the α form. The α and β descriptors now refer to the absolute structural relationships. *See anomer, Haworth representation.*

Hughes press a device to disrupt microorganisms. It consists of a steel cylinder in which a paste of the microorganisms in question, mixed with abrasives, is subjected to sudden blows by a steel piston driven by a fly-press; the piston forces the crushed material out of the cylinder into a reservoir. At temperatures below -20°C no abrasives are needed, ice crystals taking their place. *See also French pressure cell.* [After D. E. Hughes (1922-), who published the design in 1951.]

HUGO *abbr.* for Human Genome Organization; an international organization of scientists involved in the **Human Genome Project**, the global initiative directed at mapping and sequencing the human genome. It was established in 1989, and carries out a coordinating role, supporting data collection for constructing genetic and physical maps of the human genome, organizing the Single Chromosome Workshops and other workshops and promoting consideration of ethical, legal, social, and intellectual property issues. It fosters exchange of data and biomaterials. The Human Genome Project is, however, not under the central control or direction of any individual, group, or organizing committee, the work being done in many countries and coordinated by the scientists carrying out the work.

human *abbr. (in nomenclature):* h or (formerly) H; of, relating to, characteristic of, obtained from, or being a member of the species *Homo sapiens*. For names of substances or products beginning with the word human (e.g. human choriongonadotropin, human serum albumin) *see* at the corresponding general entry.

human gene index *abbr.:* HGI; a database of The Institute for Genome Research (TIGR) that integrates data from international human gene research projects, including gene expression patterns, cellular roles, functions, and evolutionary relationships.

Human Genome Project *see HUGO*

human immunodeficiency virus *see HIV.*

humanize to produce chimeric monoclonal antibodies that, by use of recombinant DNA technology, contain sequences translated from components of human immunoglobulin genes.

humanized antibody a modified antibody; since human monoclonal antibodies cannot be generated in the same way as in mice, and the body reacts to a mouse antibody the 6 complementary determining regions of a high affinity rodent monoclonal antibody are grafted on to a completely human IgG framework without loss of specific activity.

human T-cell lymphotropic virus *see HTLV.*

humectant 1 producing moisture. **2** any substance added to another substance or material to keep it moist.

humic acid any of the mixture of complex macromolecules having polymeric phenolic structures and extractable from soils and peat. It is produced by the oxidative degradation of lignin and has the ability to chelate metals, especially iron.

humidity cabinet or **humidity chamber** an enclosure in which the humidity is maintained at a constant, often high level. It is useful for keeping experimental samples or materials moist or at a predetermined moisture content.

humins the very dark-brown or black insoluble material that is produced when carbohydrate-containing proteins are subjected to acid hydrolysis.

humor the US spelling of **humour**.

humoral of, contained in, or involving the blood or other body fluid; consisting of, relating to, or involving some chemical agent or substance contained in a body fluid, especially the blood.

humoral immunity any specific immunity mediated by antibodies (i.e. **humoral antibodies**) present in blood plasma, lymph, and tissue fluids, and that may also become attached to cells.

humour or (*US*) **humor** a former name for any of the body fluids, e.g. blood, lymph.

humulin 1 human insulin made using cDNA technology. **2** the bitter aromatic principle of hops (lupulin).

humus the dark-brown or black complex mixture of colloidal organic material that results from the decomposition of plant and animal material in the soil. It is of great importance for plant growth.

hunchback a segmentation protein in insects. Similar to **ikaros**, it is a zinc-finger protein and is encoded by a **gap gene**. Compare **Krüppel**.

Hunter syndrome an alternative name for mucopolysaccharidosis II. See **mucopolysaccharidosis**. [After Charles Hunter (1872–1955), British physician.]

huntingtin see **Huntington's disease**.

Huntington's disease or **Huntington's chorea** an autosomal dominant genetic disease characterized by involuntary (choreic) movements and dementia over a 10–20 year course. It is inevitably fatal. Linking studies using a variety of RFLPs have localized the defective gene to a site on the short arm of chromosome 4. There is a selective loss of a group of neurons; the biochemical basis for their loss is unknown. The gene, which encodes a 3145-residue product, **huntingtin**, of unknown function, contains a polymorphic trinucleotide repeat of the codon for glutamine, CAG, within the coding sequence. Normals have 35–37 of these repeats. In no case has any individual with more than 41 repeats been found to be free of the disease. [After George Huntington (1850–1916), US physician.]

HU protein an abundant bacterial histone-like protein that has the ability to wrap and bend DNA *in vitro*, and is thought to play a role in chromosome DNA topology, probably by facilitating the action of gyrase. See **DNA topoisomerase** type II.

Hurler-Scheie compound syndrome an alternative name for mucopolysaccharidosis I H/S.

Hurler syndrome an alternative name for mucopolysaccharidosis I H; see **mucopolysaccharidosis**. [After Gertrude Hurler (1889–1965), Austrian physician.]

HUT (*in clinical chemistry*) *abbr.* for UDPglucose-hexose-1-phosphate uridylyl transferase (EC 2.7.7.12).

Hutchinson-Gilford syndrome a rare form of premature ageing characteristic of children and associated with truncation of **lamin A**. [After Jonathan Hutchinson (1828–1913), British surgeon, and Hastings Gilford (1861–1941), British physician.]

HVA *abbr.* for homovanillic acid.

HVE *abbr.* for high-voltage electrophoresis.

Hvidt-Nielsen mechanism a proposed mechanism to account for the kinetics of hydrogen exchange between protein molecules in solution and solvent water molecules. It is considered that protein molecules exist in solution in more than one conformational state and that hydrogen atoms in the interior of the protein molecule in the most stable conformational state are inaccessible to exchange; these hydrogen atoms may become transiently externalized, and hence accessible to exchange, in one or more of the other conformational states. [After Aasa Hvidt and S. O. Nielsen.]

Hx *abbr.* for hepxilin.

Hx^c symbol for the cyclohexyl group (alternative to cHx).

hyal+ a variant form of **hyalo+** (before a vowel).

hyaladherin a name sometimes used for proteins in the extracellular matrix that bind to **hyaluronate**.

hyaline clear, transparent; with no inclusions.

hyalo+ or (*before a vowel*) **hyal+** *comb. form* denoting glassy, transparent.

hyaluronan an alternative name for **hyaluronate**.

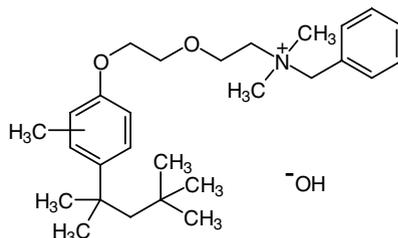

hyaluronate or **hyaluronan** the naturally occurring anionic form of hyaluronic acid; any member of a group of glycosaminoglycans, the repeat units of which consist of $\beta 1 \rightarrow 4$ -linked D-glucuronyl- ($\beta 1 \rightarrow 3$)-N-acetyl-D-glucosamine. Most preparations contain 1–2% by mass of protein, and have M_r values in the range 5×10^4 to 8×10^6 depending on source and methods of preparation and determination.

Hyaluronates are widely distributed in many tissues, especially in the vitreous humour of the eye, synovial fluid, and umbilical cord. They have an important role in the formation of proteoglycan aggregates. Hyaluronates form very viscous solutions and gels in water, a property that may be important in protecting animal organisms against invasion by bacteria.

hyaluronidase or **mucinase** or **spreading factor** a trivial name for either of the glycosidases hyaluronoglucosaminidase (EC 3.2.1.35) and hyaluronoglucuronidase (EC 3.2.1.36), and for the carbon-oxygen lyase hyaluronate lyase (EC 4.2.2.1). These enzymes have in common the ability to depolymerize hyaluronidate by cleavage of glycosidic bonds; e.g. hyaluronoglucosaminidase catalyses the random hydrolysis of 1,4-linkages between N-acetyl- β -D-glucosamine and D-glucuronate residues in hyaluronate. Hyaluronidases occur in certain animal tissues, e.g. sperm acrosome, and in some bacteria, e.g. *Clostridium* spp., and enhance the penetration of various substances and pathogens through the extracellular matrix (hence the name 'spreading factor').

hyaluronidase deficiency an alternative name for **mucopolysaccharidosis IX**.

hyamine hydroxide methylbenzethonium hydroxide; a water-soluble organic base, useful biochemically because it and some of its salts are soluble in organic solvents such as chloroform and toluene. It is therefore used to absorb radioactive CO_2 released during metabolic incubations; the resultant hyamine carbonate can then be dissolved in a scintillation cocktail for counting. It is also used as a topical anti-infective agent.

hybrid 1 something derived from heterogeneous sources or composed of different or incongruous elements. **2** (*in genetics*) the offspring of two animals or plants of different species, or (less strictly) different varieties. **3** (*in chemistry*) a bond or valence orbital obtained by the linear combination of two or more different atomic orbitals.

hybrid antibody any artificially produced immunoglobulin molecule in which the combining sites are of different specificities.

hybrid-arrested translation *abbr.*: HART; a method for analysing the relationship between a DNA sequence, its corresponding messenger RNA (mRNA), and the protein for which it codes, based on the observation that mRNA when hybridized with its complementary DNA is not translated in eukaryotic cell-free systems whereas heat-induced dissociation of the hybrid completely restores translational activity. The method has been used to map precisely specific protein-coding regions in **restriction fragments** of DNA. See also **hybrid-released translation**.

hybrid cell any cell containing the nuclei and cytoplasm from differing cells, formed artificially by **cell fusion**.

hybrid DNA 1 artificial duplex DNA produced by collinear (i.e. covalent) union of two (or more) fragments of duplex DNA (i.e. **recombinant DNA**; see also **plasmid chimera**). **2** artificial duplex DNA produced by collateral (hydrogen bonded) union of two incompletely complementary, single strands of DNA. Compare **DNA-RNA hybrid**.

hybridization or **hybridisation 1** the act or process of forming a genetic **hybrid** (def. 2) by cross-breeding, or other unnatural recombination. **2** the act or process of forming a macromolecular **hybrid** (def. 1) by the artificial recombination of subunits, e.g. of polynu-

cleotide strands or polypeptide chains. **3** the mathematical combination of atomic orbitals to form an orbital **hybrid** (def. 3).

hybridization analysis a method of testing for complementarity in the base sequences of two polynucleotides from different sources, based on the ability of complementary single-stranded DNA molecules to form duplex DNA molecules on being annealed together, and the ability of single strands of DNA and RNA similarly to form **DNA–RNA hybrids**.

hybridization probe *see* **probe** (def. 3).

hybrid myeloma *see* **hybridoma**.

hybridoma any permanent **cell line** derived from an artificial **somatic cell hybrid** formed between a cultured neoplastic lymphocyte and a normal primed B or T lymphocyte, all the cells of which express the specific immune potential of the normal parental cell. The term is derived from a contraction of 'hybrid' and 'myeloma'. Hybridomas are produced by the technique of **cell fusion**, using, e.g., a suspension of mouse myeloma or thymoma cells from a selected established cell line to which is added a preparation of spleen cells (predominantly normal lymphocytes) from mice or other animals that have been immunized against a specified antigen. After cell fusion, selection is aided by the use of **HAT** medium, which kills HGPRT[−] myeloma cells, and lymphocytes that have not fused do not survive in culture. This treatment thus selects for the immortalized hybridoma cells that retain the lymphocyte HGPRT. Such hybrid cells are both permanently adapted to growth in culture and capable of forming specific antibody-producing tumours *in vivo*. A B-cell hybridoma continuously secretes pure **monoclonal antibody** of a predetermined specificity and may thus be used for the facile large-scale production of such antibody.

hybrid-released translation *abbr.*: HRT; a method in which cloned DNA is bound to a nitrocellulose filter and hybridized with unfractionated mRNA, or even total cellular RNA. After washing the filter, any mRNA that has hybridized with the DNA is eluted and translated in a cell-free translation system, thus revealing the product that is encoded by the DNA. *See also* **hybrid-arrested translation**.

hydantoin *generic name for* 2,4-imidazolidinedione or its derivatives. A hydantoin is formed by the reaction of an isocyanate, commonly phenylisocyanate, with the free amino group of an amino acid, and the cyclization of the hydantoic acid derivative initially formed. When an isocyanate reacts with the N-terminal amino group of a peptide, the corresponding hydantoin is formed, with simultaneous cleavage of the substituted N-terminal amino-acid residue from the peptide.

hydr+ a variant form of **hydro+** (sometimes before a vowel).

hydrase an obsolete term for **hydratase**.

hydratase *see* **dehydratase**.

hydrate **1** any adduct of water with another compound or element, usually in definite molecular proportions. **2** to form a **hydrate** (def. 1); to undergo **hydration**. **3** to cause to take up or to combine with water. **4** to maintain or restore the normal proportion of water in the body (of someone or something). —**hydrated** *adj.*

hydration **1** the act or process by which water molecules surround and bind to molecular entities. **2** the addition of H and OH to a chemical species. **3** the formation of a **hydrate** (def. 1). **4** the quality or state of being hydrated. **5** the introduction of additional water into the body (of something or someone). *Compare* **anhydrous**, **dehydration**, **solvation**.

hydration shell the layer of water molecules surrounding an ion or molecule in aqueous solution.

hydraulic **1** operated by pressure transmitted through a liquid, e.g. through water or oil. **2** of or concerning hydraulics (i.e. fluid mechanics).

hydrazine H₂N–NH₂; an oily liquid, fuming in air, that is very toxic and possibly a carcinogen. It is available as a hydrate and as various salts. *See also* **hydrazinolysis**.

hydrazinolysis the cleavage of amide and peptide bonds by heating at 100°C with **hydrazine** in anhydrous conditions to form the corresponding acyl hydrazides. This reaction is useful in the determination of C-terminal amino-acid residues in peptides and proteins as all the other amino-acid residues will be converted to their hy-

drazides and only the C-terminal amino acid will be set free in an underivatized form.

hydrazone any condensation product of the type R'R''C=N–NHR, formed between carbonyl compounds (R'R''=CO) and hydrazine or a substituted hydrazine. *See also* **osazone**, **phenylhydrazone**.

hydride **1** the ion H[−], hydrogen anion. It has an independent existence only in the salt-like hydrides formed by strongly electropositive elements (*see* def. 2) but is also sometimes regarded as participating in the formation of complex hydrides (*see* def. 4) and in certain oxidation–reduction reactions (*see* **hydride-ion transfer**). **2** any stoichiometric binary compound of hydrogen with one of many (but not all) of the elements in groups 1, 2, and 3 of the IUPAC **periodic table**, e.g. NaH or CaH₂. Such hydrides are salt-like ionic compounds, are solids at ambient temperatures, and on fusion can be electrolysed (dihydrogen then being liberated at the anode). They are readily decomposed by water and are potent reducing agents. **3** Any stoichiometric compound of hydrogen with one (or sometimes more than one) of many of the elements in other groups of the periodic table, and also with boron. Such hydrides are volatile covalent compounds containing one atom of the element per molecule, e.g. PbH₄, or sometimes more than one, e.g. Si₃H₈; in the latter type certain of the hydrogen atoms may be present as bridges, as in B₂H₆. **4** any salt-like compound containing a complex anion that may be considered as formed by coordination of a hydride ion to an uncharged hydride, e.g. KBH₄ (*see* **borohydride**) or LiAlH₄; such compounds are widely used in organic chemistry as reducing agents or for introduction of tritium, ³H. **5** any (frequently nonstoichiometric) product formed by uptake of dihydrogen by certain transition metals, especially palladium.

hydride-ion transfer *term conventionally often applied to a chemical or enzyme-catalysed oxidation–reduction reaction involving the transfer from one molecule to another of a hydrogen atom together with its associated pair of bonding electrons. Such a reaction may notionally be considered to involve the transfer of a hydride ion without such an ion ever existing as a free entity. Examples include the Cannizzaro reaction and reactions of the general type*

where M is a substrate molecule undergoing enzymic reduction, to which a hydride ion is transferred from NADH.

hydrindantin the reduced form of **ninhydrin**. It is sometimes used in conjunction with ninhydrin in the chromogenic determination or visualization of amino or imino groups.

hydron a former name for **hydrogen ion**.

hydro+ or (sometimes before a vowel) **hydr+** *comb. form* **1** indicating or denoting water, liquid, or fluid. **2** indicating the presence of hydrogen in a compound.

hydrocarbon **1** any organic compound composed exclusively of hydrogen and carbon. **2** of, pertaining to, or being a **hydrocarbon** (def. 1) or a chemical group or side chain composed of hydrogen and carbon only.

hydrocarbyl any univalent group formed from a hydrocarbon by removal of a hydrogen atom; e.g. methyl (from methane).

hydrocolloid any colloidal substance for which the dispersing liquid is water or an aqueous solution.

hydrocortisone an alternative name for **cortisol**.

hydrodynamic **1** of or concerned with the mechanical properties of fluids. **2** of, pertaining to, or concerned with **hydrodynamics**.

hydrodynamic particle the entity formed by any (macro)molecule in solution together with its solvation shell.

hydrodynamic radius the radius of a (macro)molecule or other particle in solution as determined by a hydrodynamic method, e.g. sedimentation equilibrium.

hydrodynamics the branch of physics concerned with the forces acting on or exerted by fluids.

hydrodynamic shear the microscopic shear force caused by the motion of different layers in a fluid, where the layers move at different velocities. This acts to break any molecule sufficiently long to bridge the layers, e.g. DNA.

hydrodynamic volume (*of a molecule in solution*) the sum of the time-average of the molecular volume and the volume of the solvent molecules associated with it.

hydrogel any gel (def. 1) in which water is the liquid component.

Compare hydrosol.

hydrogen *symbol:* H; the lightest of the elements and the most abundant in the universe. It exists as an odourless, colourless, flammable diatomic gas, dihydrogen, H₂, and forms compounds with most of the elements, being present in water and all organic compounds. There are two naturally occurring isotopes, hydrogen-1 (**protium**) and hydrogen-2 (**deuterium**), and one artificial isotope, hydrogen-3 (**tritium**), which is radioactive.

hydrogenase an enzyme that catalyses the production or consumption of dihydrogen. Hydrogen is produced by hydrogenases during the photosynthetic cleavage of water, and by fermentation processes in many anaerobic organisms. Hydrogen is also produced by **nitrogenase** as a by-product of the nitrogen-reducing reaction, but this enzyme not defined as a hydrogenase. Hydrogen is consumed by hydrogen-uptake hydrogenases in many bacteria, with the concomitant reduction of compounds such as oxygen, which is reduced to water, sulfate to sulfide, or carbon monoxide to methane. One of the most common hydrogen-consuming hydrogenases is hydrogen:quinone oxidoreductase, EC 1.12.7.2; in nitrogen-fixing bacteria, this enzyme recycles H₂ produced by nitrogenase to increase the production of ATP and to protect nitrogenase against inhibition or damage by O₂. In order to react with other electron carriers the hydrogenases employ various cosubstrates. Hydrogen dehydrogenase, EC 1.12.1.2, catalyses the reaction: H₂ + NAD⁺ = H⁺ + NADH and contains FMN. This enzyme is structurally related to mitochondrial Complex I. EC 1.12.1.3 is similar, but reduces NADP⁺. Cytochrome-C₃ hydrogenase, EC 1.12.2.1 is used by sulfate-reducing bacteria. Almost all hydrogenases are iron-sulfur proteins. The defining characteristic is an active site containing iron that has carbonyl and usually cyanide ligands. Two main nonhomologous classes are recognized: (1) hydrogenases containing an H cluster comprising a dimer of iron atoms linked to a [4Fe-4S] cluster, known as [Fe]- or [FeFe]-hydrogenases (*see iron hydrogenase*), and those containing nickel and iron (*see nickel-iron-hydrogenase*). In addition there is a third type, containing iron and no iron-sulfur clusters, of which the only example known so far is 5,10-methenyltetrahydromethanopterin hydrogenase (EC 1.12.98.2).

hydrogenate to undergo or cause to undergo reduction by addition of the hydrogen atoms of dihydrogen, usually with the aid of a catalyst such as finely divided forms of nickel, palladium, or platinum. The process is of industrial importance in petroleum refining, the petrochemical industry and the hardening of fats. —**hydrogenated** *adj.*; **hydrogenation** *n.*

hydrogen bond an association between an electronegative atom, e.g. fluorine, oxygen, nitrogen, or sulfur, and a hydrogen atom attached to another such electronegative atom. Although **hydrogen bonding** is due to interaction between dipoles, the force of attraction is large enough to permit formation of aggregates of small molecules or to stabilize the conformation of many macromolecules. The spatial relation of the donor and acceptor atoms is such that the hydrogen atom lies very close to the straight line between them.

hydrogen carrier a name sometimes used for any electron carrier that undergoes oxidation-reduction reactions by the loss or gain of hydrogen atoms, e.g. NADH, FADH.

hydrogen dehydrogenase the recommended name for the enzyme, EC 1.12.1.2, also known as **hydrogenase**, that catalyses the reaction:

It is a flavoprotein; iron and nickel are cofactors; the molecule is heterotetrameric. It may form part of a system involving **hydrogenase** (def. 1). For example, in *Alcaligenes eutrophus*, the α and γ subunits form one dimer (FMN, 4Fe-4S cluster, NADH oxidoreductase); and the β and δ subunits form the other dimer, which exhibits **hydrogenase** activity with artificial electron acceptors.

hydrogen-deuterium exchange *see* **hydrogen exchange**.

hydrogen electrode an electrode that is reversible to hydrogen ions and dihydrogen molecules. It is formed by bubbling pure dihydrogen gas over a metal wire or a piece of foil whose surface is able to catalyse the reaction:

where e represents an electron. The most useful catalyst is platinum black on a platinum substrate. Hence the catalyst establishes an equilibrium between dihydrogen molecules (or hydrogen atoms) and the hydrogen ions (i.e. hydrons) in the solution in which the metal electrode is immersed. If the partial pressure (in atm) of dihydrogen gas at the electrode is p_{H_2} , the half-cell potential, E_{H} , of reaction (1) is given by:

$$E_{\text{H}} = E_{\text{H}}^{\circ} - (RT/F)\ln(a_{\text{H}^+}/p_{\text{H}_2}) \quad (2)$$

where R is the gas constant, F the faraday constant, T the thermodynamic temperature, and a_{H^+} the hydrogen-ion activity. E_{H}° , the standard potential of the hydrogen electrode, is, by convention, zero at all temperatures, hence at $p_{\text{H}_2} = 1$, the usual standard state, equation (2) becomes:

$$E_{\text{H}} = -(RT/F)\ln a_{\text{H}^+}.$$

Thus the hydrogen electrode is the ultimate reference electrode for the determination of pH values. It should be noted that the potential of any single electrode cannot be determined by itself; another electrode must be connected to the solution.

hydrogen exchange or **hydrogen-deuterium exchange** a technique useful for demonstrating conformational differences between samples of the same protein and for providing insight into the dynamics of protein conformations in solution. It can be observed using nuclear magnetic resonance spectroscopy. The method is based on observation of the kinetics of the noncatalysed exchange of hydrogen atoms in peptides and proteins with protons or other hydron isotopes in aqueous solutions and the effects of pH (or p²H), temperature, etc. on the process.

hydrogen ion or (*formerly*) **hydriion** the cation, H⁺, derived from the hydrogen atom. In aqueous solution it is mostly in the hydrated form, oxonium (H₃O⁺). In nonaqueous solution it is likely, by analogy, that it is attached particularly to one solvent molecule, e.g. ROH₂⁺ in an alcohol, R₂COH⁺ in a ketone, RNH₃⁺ in an amine, etc. *See also* **hydron**, **proton** (defs 1, 2).

hydrogen-ion concentration *see* **pH**.

hydrogen-ion pump any of a number of membrane proteins that transport hydrogen ions through membranes. The H⁺-transporting ATPase of fungi and plants (EC 3.6.1.35) has an action similar to that of the **H⁺-transporting ATP synthase** of mitochondria, but without coupling factors; it is an integral membrane glycoprotein. The proton gradient it generates drives the active transport of nutrients by H⁺-symport. The **vacuolar ATPase** is another type.

hydrogen lamp or **hydrogen discharge lamp** a high-voltage discharge tube with a quartz window and containing dihydrogen at low pressure, in which the glow produced by excitation of the dihydrogen molecules is concentrated in a long capillary tube joining the two electrodes; this arrangement gives increased intensity. It produces a continuous emission spectrum over the range 180–350 nm. *See also* **deuterium (discharge) lamp**.

hydrogenlyase *see* **hydrogenase** (def. 1).

hydrogenosome an organelle with a double membrane occurring in the cytoplasm of some anaerobic flagellate protozoans. They are chromatic granules of high density containing enzymes, including hydrogenase, that catalyse the conversion of pyruvate to acetate, CO₂, and H₂. These organelles may substitute for mitochondria (which are absent from such organisms).

hydrogen peroxide H₂O₂; the product of reactions catalysed by NADPH oxidase of phagocytes, cytochrome oxidase of mitochondria, acyl-CoA dehydrogenase of peroxisomes, glycolate oxidase of glyoxysomes, and xanthine oxidase of liver and plasma. It is rapidly eliminated by catalase, glutathione peroxidase, and thioredoxin-linked reactions. Although H₂O₂ is poorly reactive, it is rapidly converted into the highly reactive hydroxyl radical (–OH) by transition metal ions, especially iron, and by ultraviolet light. In some plants it is a second messenger in the response to hormones, pathogenic infection, and abiotic stress. .

hydrolase any enzyme of class EC 3 that catalyses the hydrolysis of various bonds, e.g. C–O, C–N, C–C, phosphoric anhydride bonds, etc. Often the name of a hydrolase is formed from the name of the substrate and the suffix ‘-ase’.

hydrolysate or (sometimes US) **hydrolyzate** any substance or mixture of substances produced by hydrolysis.

hydrolyse or (US) **hydrolyze** to subject to, to undergo, or to effect hydrolysis. —**hydrolysable** or (US) **hydrolyzable** *adj.*; **hydrolysis** or (US) **hydrolyzation** *n.*

hydrolysis (*pl.* **hydrolyses**) the rupture of one or more chemical bonds by reaction with, and involving the addition of, the elements of water; **solvolysis** by water.

hydrolytic of, pertaining to, producing, or produced by hydrolysis.

hydrolyzate an alternative US spelling of **hydrolysate**.

hydrolyze an alternative US spelling of **hydrolyse**.

hydrometer an instrument used to measure the **density**, or **relative density**, of a liquid. It usually consists of a glass (or plastic) bulb, weighted at the bottom so that it floats upright, and fitted with a stem carrying a scale. The point on the scale that is level with the surface of the liquid indicates the (relative) density of the liquid.

hydron *symbol:* H⁺; *the recommended name for the cation derived from an atom of hydrogen in its natural isotopic abundance. See also hydrogen ion, proton* (defs 1, 2).

hydronate to combine with a **hydron** or **hydrans**. —**hydronation** *n.*

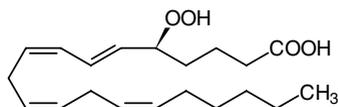

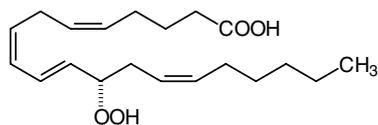

hydronium ion an alternative name (now disfavoured) for **oxonium** (def. 1).

hydropathy a measure of hydrophobicity. *See hydrophobic.* —**hydropathic** *adj.*

hydropathy profile a graphical representation of the hydropathic nature of a protein sequence. Within a profile, hydropathy values are calculated in a sliding window and plotted for each residue in the sequence. Resulting graphs show characteristic peaks and troughs, corresponding to the most hydrophobic and hydrophilic regions of the sequence respectively. They are most frequently used to predict the presence of **transmembrane domains**.

hydroperoxide any organic compound in which one hydrogen atom of a hydrocarbon is replaced by the —O—OH group.

hydroperoxyeicosatetraenoate *abbr.:* HpETE; any of various related products of the action of **lipoxygenase** on arachidonate, (all-*Z*)-eicosa-5,8,11,14-tetraenoate. The most notable are 5(*S*)-HpETE, (6*E*,8*Z*,11*Z*,14*Z*)-(5*S*)-5-hydroperoxyeicosa-6,8,11,14-tetraenoate; 12(*S*)-HpETE, (5*Z*,8*Z*,10*E*,14*Z*)-(12*S*)-12-hydroperoxyeicosa-5,8,10,14-tetraenoate; and 15(*S*)-HpETE, (5*Z*,8*Z*,11*Z*,13*E*)-(15*S*)-15-hydroperoxy-5,8,11,13-eicosatetraenoate. Their species distribution follows that of the lipoxygenases. HpETEs function as precursors of hydroxyeicosatetraenoates, leukotrienes, dihydroxyeicosatetraenoates, hepxilins, and lipoxins, but they also have biological activity in their own right, e.g. regulation of electrolyte flux, release of histamine, regulation of eicosanoid and corticosterone synthesis, and regulation of oocyte maturation. 12-HpETE inhibits platelet thromboxane synthase and prostaglandin-endoperoxide synthase, and acts as a second messenger in *Aplysia* sensory neurons.

5(*S*)-HpETE12(*S*)-HpETE

hydroperoxyoctadecadienoate *abbr.:* HpODE; any of various related products of the action of **lipoxygenase** on linoleate, (all-*Z*)-octadeca-9,12-dienoate. The most notable are 9(*S*)-HpODE, (10*E*,12*Z*)-(9*S*)-octadeca-10,12-dienoate; and 13(*S*)-HpODE, (9*Z*,11*E*)-(13*S*)-octadeca-9,11-dienoate.

hydrophilic 1 tending to dissolve in water; having a strong affinity for water; readily mixing with or wetted by water. *See also lyophilic.* **2 polar.** *Compare hydrophobic.* —**hydrophilicity** *n.*

hydrophobic 1 tending not to dissolve in water; having a low affinity for water; not readily mixing with or wetted by water. **2 nonpolar.** *Compare hydrophilic. See also lyophobic.* —**hydrophobicity** *n.*

hydrophobic bond a term sometimes used incorrectly for a **hydrophobic interaction**.

hydrophobic chromatography or **hydrophobic affinity chromatography** or **hydrophobic interaction chromatography** a technique for the separation and purification of proteins and other substances by **adsorption chromatography** on polysaccharide or other gels containing lipophilic substituents (which may or may not bear terminal ionizable groups). These hydrophobic centres on the gel interact with nonpolar amino-acid residues exposed on the surface of the protein molecules being separated.

hydrophobic interaction or (*discouraged*) **apolar bond** the tendency of hydrocarbons (or of lipophilic hydrocarbon-like groups in solutes) to form intermolecular or intramolecular aggregates in polar solvents. *See also apolar interaction.*

hydrophobic pocket (*in a protein*) a binding site (crevice, pocket) that contains mostly hydrophobic amino acids. For example, the binding site for the aromatic side chains of the specific substrates in **chymotrypsin** is a hydrophobic pocket, consisting of a groove in the enzyme, 100–120 nm deep, and 35–40 nm by 55–65 nm in cross section, lined with non-polar amino-acid side chains. *See also heme pocket.*

hydrophobic residue any building block of a polymer, the residue of which in that polymer is hydrophobic. The term is applied especially to amino-acid residues exhibiting such properties in polypeptides (e.g., valine, leucine, phenylalanine).

hydrophobin any of a family of membrane proteins present in some fungi that are involved in cell adhesion and morphogenesis. They have a characteristic domain that contains eight cysteine residues.

hydroquinone 1 1,4-benzenediol; *p*-dihydroxybenzene; quinol. *Compare p-benzoquinone, pyrocatechol. See also quinhydrone.* **2** any member of a class of aromatic *p*-diols derivable from *p*-quinones (*see quinone* (def. 2)) by reduction of two CO groups to COH groups with any necessary rearrangement of double bonds; any compound containing a quinol nucleus. *See also quinol* (def. 2), **semiquinone**. *Compare catechol* (def. 2).

hydrosol any **sol** in which water is the liquid component. *Compare hydrogel.*

hydrous (*of a chemical compound*) containing combined water (usually in stoichiometric proportions).

hydroxide 1 or (*formerly*) **hydroxyl** the ion OH⁻. **2** any inorganic or organic compound containing or dissociating to give this ion. Hydroxides that are soluble in water, and can dissociate, give aqueous solutions with an alkaline reaction (pH > 7).

hydroxo+ *comb. form* indicating the presence of a OH⁻ ligand in a coordination compound.

hydroxocobalamin or **vitamin B_{12b}** a form of vitamin B₁₂ in which a hydroxide ion is in coordinate linkage to the sixth (i.e. β) position on the cobalt atom in a molecule of **cobalamin**; the conjugate base of aquacobalamin.

hydroxonium ion an alternative name (now disfavoured) for **oxonium** (def. 1).

hydroxy denoting the presence in a compound of one or more **hydroxyl** groups.

hydroxy+ *comb. form* (*in chemical nomenclature*) denoting the presence of one or more **hydroxyl** groups; the number of hydroxyl groups may be specified, e.g. dihydroxy+ (two), trihydroxy+ (three), etc.

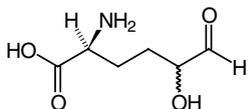

hydroxy acid any organic acid containing one or more **hydroxyl** groups.

2-hydroxy-acid oxidase EC 1.1.3.15; *systematic name:* (*S*)-2-hydroxy-acid: oxygen 2-oxidoreductase; *other name:* glycolate oxidase; an enzyme that catalyses the oxidation by dioxygen of (*S*)-2-hy-

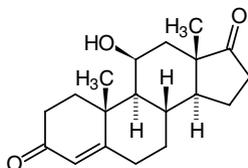

droxy-acid to 2-oxo-acid and H_2O_2 . It is a peroxisomal enzyme in plants that is involved in the conversion of glycolate to glycine in **photorespiration**. The coenzyme is FMN.

3-hydroxyacyl-CoA dehydrogenase EC 1.1.1.35; *systematic name*: (S)-3-hydroxyacyl-CoA:NAD⁺ oxidoreductase; *other names*: β -hydroxyacyl dehydrogenase; β -keto-reductase; an enzyme of the **beta-oxidation system**. It catalyses the oxidation by NAD⁺ of *s*-3-hydroxyacyl-CoA to 3-oxoacyl-CoA with formation of NADH. See also **fatty-acid oxidation complex**, **peroxisomal bifunctional enzyme**.

hydroxyallysine 5-hydroxy-6-oxonorleucine; 2-amino-5-hydroxyadipaldehyde. An α -amino acid not normally found in proteins, but enzymically formed from 5-hydroxylysine *in situ* as an intermediate in the creation of covalent cross-links between adjacent polypeptide strands during the maturation of certain connective tissue proteins, e.g. collagen, elastin. See also **allysine**.

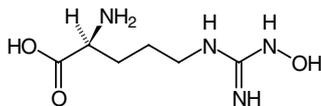

11 β -hydroxy-4-androstene-3,17-dione 4-androsten-11 β -ol-3,17-dione; a 17-oxo steroid formed from androstenedione by steroid 11 β -monooxygenase (EC 1.14.15.4).

hydroxyapatite or **hydroxylapatite** a crystallized form of calcium orthophosphate hydroxide, $Ca_{10}(PO_4)_6(OH)_2$, virtually insoluble in water and in many aqueous solvents; it occurs as a mineral in phosphate rock. The main mineral component of bone, cartilage, and tooth approximates in composition to hydroxyapatite, small proportions of Ca^{2+} and OH^- being replaced respectively by Mg^{2+} and F^- ; trace amounts of other ions may be present as well. Hydroxyapatite may also occur in granules in mitochondria. Chemically prepared hydroxyapatite is useful in the separation of proteins or nucleic acids by **adsorption chromatography**. It is used in orthopedic and dental prostheses and in the prevention of osteoporosis.

***N*^ω-hydroxy-L-arginine** *abbr.*: L-NHA; a derivative of L-arginine in which one of the guanidine nitrogens is oxidized to an *N*-hydroxy group. It is an intermediate in the formation of nitric oxide from L-arginine; it may function as an intercellular NO carrier, and as a vasodilator in its own right.

***p*-hydroxybenzoic acid** 4-hydroxybenzoic acid; an intermediate in the synthesis of **ubiquinone** from tyrosine in mammals.

γ -hydroxybutyrate or **gamma-hydroxybutyrate** a rapid-acting central nervous depressant. It is abused because it produces euphoric and hallucinogenic states and is alleged to produce muscle growth. It is one of the 'date rape' drugs.

3-hydroxybutyrate cycle or **3-hydroxybutyrate shuttle** an intracellular metabolic cycle that can transfer reducing equivalents from the cytosol to the mitochondria in liver. Extramitochondrial NADH is oxidized to NAD⁺ by acetoacetate, which is reduced to D(-)-3-hydroxybutyrate; the latter then passes into the mitochondria

where it is reoxidized to acetoacetate by intramitochondrial NAD⁺. The acetoacetate passes out into the cytosol thereby completing the cycle.

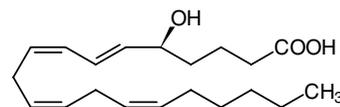

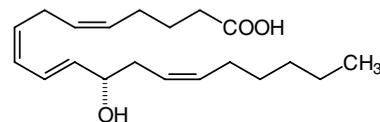

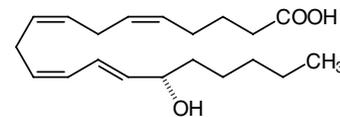

3-hydroxybutyrate dehydrogenase EC 1.1.1.30; *other name*: D- β -hydroxybutyrate dehydrogenase; an enzyme that catalyses the reaction:

α -hydroxybutyrate (2-hydroxybutanoate) dehydrogenase an *alternative name* for the LD₁ isoenzyme of **lactate dehydrogenase** (EC 1.1.1.27).

4-hydroxybutyric aciduria an autosomal recessive disorder caused by mutation in the gene for succinic-semialdehyde dehydrogenase. The excess succinic semialdehyde is reduced by 4-hydroxybutyrate dehydrogenase (EC 1.1.1.61) and the product is excreted in urine.

hydroxyeicosatetraenoate *abbr.*: HETE or mono-HETE; any of various related products arising, either spontaneously or by the action of glutathione peroxidases, from reduction of **hydroperoxyeicosatetraenoates**. The main forms are the 5-, 12-, and 15-HETEs, resulting from the action of 5-, 12-, and 15-**lipoxigenase** enzymes, but 8-, 9-, 11-, 16-, 17-, 18-, 19-, and 20-HETEs are known. The hydroxy group in most HETEs is of the *S* configuration, but those of *R* configuration are known, e.g. 12(*R*)-HETE from psoriatic lesions; 12(*R*)-HETE and 11(*R*)-HETE are found in sea-urchin eggs. The three main HETEs are: (6*E*,8*Z*,11*Z*,14*Z*)-(5*S*)-5-hydroxyeicosa-6,8,11,14-tetraen-1-oate, 5(*S*)-HETE; (5*Z*,8*Z*,10*E*,14*Z*)-(12*S*)-12-hydroxyeicosa-5,8,10,14-tetraen-1-oate, 12(*S*)-HETE; and (5*Z*,8*Z*,11*Z*,13*E*)-(15*S*)-15-hydroxyeicosa-5,8,11,13-tetraen-1-oate, 15(*S*)-HETE. Their tissue distribution follows that of **lipoxigenases**. 15(*S*)-HETE can act as a precursor for 5(*S*),15(*S*)-dihydroxyeicosatetraenoate and **lipoxins**. 5-HETE and 12-HETE are chemoattractants, 12(*R*) being more potent than 12(*S*), but 5(*S*) being more potent than 5(*R*); 8(*R*)-HETE, synthesized by starfish oocytes, is orders of magnitude more potent than 8(*S*)-HETE in inducing oocyte maturation.

5(*S*)-HETE12(*S*)-HETE15(*S*)-HETE

hydroxy fatty acid any member of a class of fatty acids having a hydroxyl group, usually at the 2- or 3-position. 2-D(-)-hydroxy

5-hydroxyindoleacetaldehyde

fatty acids are widespread minor constituents of plant and some animal (wool, skin) lipids; 3-L(+)-hydroxy fatty acids are found in low amounts in plant and bacterial lipids (e.g. in **mycolic acids**). Mid-chain hydroxy acids and polyhydroxy acids also occur in plant lipids.

5-hydroxyindoleacetaldehyde *see* **5-hydroxyindole metabolism**.

5-hydroxyindoleacetic acid *abbr.*: 5-HIAA; a metabolite of **5-hydroxytryptamine**, produced by oxidative deamination catalysed by the enzyme **monoamine oxidase**, followed by oxidation to 5-HIAA. *See also* **5-hydroxyindole metabolism**.

5-hydroxyindole metabolism the metabolism of 5-hydroxytryptophan and its derivatives; it is of particular interest because it is concerned with the synthesis and degradation of the neurotransmitter 5-hydroxytryptamine (i.e. **serotonin**). Serotonin is converted to 5-hydroxy-3-indoleacetaldehyde by **monoamine oxidase**, and thence to either 5-hydroxytryptophan (3%) or 5-hydroxy-3-indoleacetic acid (5-HIAA) (97%), and these are excreted in the urine. Urinary 5-HIAA is measured as a diagnostic aid in cases of carcinoid syndrome, as the tumour converts large amounts of dietary tryptophan to serotonin.

hydroxyl 1 the (covalently linked) -OH group in any chemical compound. **2** a former name for the hydroxide ion; *see* **hydroxide** (def. 1).

hydroxylamine 1 NH₂-OH; a chemical mutagen that causes the deamination of cytosine residues in DNA so that, during subsequent replication of the DNA, the altered cytosine pairs with adenine rather than with guanine, causing G-C to A-T transitions. Hydroxylamine is an intermediate in the oxidation of ammonium in nitrifying bacteria, and in the reverse reaction in denitrifying bacteria. It may be used to cleave specifically Asp-Gly bonds in peptides. **2** any organic compound of the type RNH-OH.

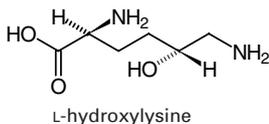

hydroxylapatite an alternative name for **hydroxyapatite**.

hydroxylase the common name for many monooxygenase and a few dioxygenase enzymes that catalyse hydroxylation reactions.

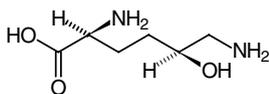

hydroxylate to introduce one or more hydroxyl (def. 1) groups into a compound, often by the replacement of hydrogen atom(s). —**hydroxylation** *n*.

hydroxylation-induced migration an alternative name for **NIH shift**.

hydroxyllysine the trivial name for δ -hydroxyllysine; δ -hydroxy- α , ϵ -diaminocaproic acid; 5-hydroxy-2,6-diaminohexanoic acid; H₂N-CH₂-CHOH-[CH₂]₂-CH(NH₂)-COOH; a chiral α -amino acid. Because the molecule of hydroxyllysine possesses two chiral centres, four isomeric forms are possible, comprising an enantiomeric (D₃ and L₃) pair of each of two (*erythro* and *threo*) diastereoisomers (the pair of *threo* enantiomers are sometimes known as **allohydroxyllysine**). L-Hydroxyllysine (*symbol*: 5Hyl or Hyl or Lys(5-OH) or (formerly) Hyls), *erythro*-5-hydroxy-L₃-lysine, is a **noncoded amino acid** found in peptide linkage in proteins (mainly collagen). In collagen, 15–20% of the lysine residues are enzymically converted to hydroxyllysine residues while the growing peptide chains are still attached to ribosomes; some of the hydroxyl groups of the hydroxyllysine side chains are subsequently glycosylated.

L-hydroxyllysine

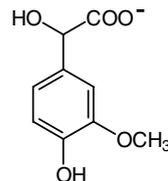

L-allohydroxyllysine

hydroxy-methoxymandelate *abbr.*: HMMA; 4-hydroxy-3-methoxymandelate; often (incorrectly) known as vanillylmandelate

[hydroxymethylglutaryl-CoA reductase (NADPH)]-phosphatase

(*abbr.*: VMA); the L enantiomer is the end product of **catecholamine** catabolism, and is excreted in the urine. In clinical chemistry the measurement of HMMA in urine is used to detect excessive biosynthesis of catecholamines, as, e.g., in **pheochromocytoma**.

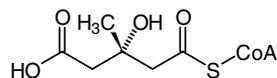

hydroxymethylbilane synthase EC 4.3.1.8; *systematic name*: porphobilinogen ammonia-lyase (polymerizing); *other names*: porphobilinogen deaminase; pre-uroporphyrinogen synthase. An enzyme that catalyses the conversion of four molecules of porphobilinogen to hydroxymethylbilane and four molecules of ammonia; dipyrromethane is a cofactor. Together with **uroporphyrinogen-III synthase** it is responsible for the step in heme biosynthesis in which four porphobilinogen molecules are condensed to form uroporphyrinogen III.

5-hydroxymethylcytosine *abbr.*: HMC; a minor base occurring in some types of DNA, e.g. in T4 bacteriophage.

hydroxymethylglutaric aciduria an autosomal recessive disease characterized by hypoglycemia, metabolic acidosis, hyperammonemia, and excessive urinary excretion of hydroxymethylglutarate. It can lead to coma and death in infancy. It is caused by inactivating mutations in the gene (at 1p35.1) for hydroxymethylglutaryl-CoA lyase.

hydroxymethylglutaryl-CoA *abbr.*: HMG-CoA; β -hydroxy- β -methylglutaryl-CoA; (S)-3-hydroxy-3-methylglutaryl-CoA; an important intermediate in the synthesis of cholesterol, farnesyl and geranyl derivatives, and ketone bodies, and in the catabolism of leucine. *See also* **hydroxymethylglutaryl-CoA reductase**, **hydroxymethylglutaryl-CoA lyase**.

hydroxymethylglutaryl-CoA lyase *abbr.*: HMG-CoA lyase; EC 4.1.3.4; *systematic name*: (S)-3-hydroxy-3-methylglutaryl-CoA acetoacetate lyase. An enzyme that catalyses the formation of acetyl-CoA and acetoacetate from (S)-3-hydroxy-3-methylglutaryl-CoA. It requires Mg²⁺ or Mn²⁺ for activity. In mammals it is a homodimer (each subunit in humans contains 298 amino acids) mostly of mitochondrial matrix but also present in peroxisomes that converts hydroxymethylglutaryl-CoA to acetoacetate in the synthesis of **ketone bodies**. Deficiency leads to hydroxymethylglutaric aciduria.

hydroxymethylglutaryl-CoA reductase (NADPH) *abbr.*: HMG-CoA reductase; EC 1.1.1.34; *systematic name*: (R)-mevalonate:NADP⁺ oxidoreductase (CoA-acylating). An enzyme that catalyses a reaction between (S)-3-hydroxy-3-methylglutaryl-CoA and two molecules of NADPH to form (R)-mevalonate, CoA, and two molecules of NADP⁺. Its function is to reduce HMG-CoA to (R)-mevalonate. In mammals it is an integral membrane glycoprotein of endoplasmic reticulum and peroxisomes. It catalyses a rate-limiting step and is an important regulatory enzyme in pathways for the synthesis of cholesterol and other sterols. It is the target for therapeutic strategies for reducing plasma cholesterol. *See also* **dephospho-[reductase kinase] kinase**.

[hydroxymethylglutaryl-CoA reductase (NADPH)] kinase EC 2.7.1.109; *other name*: reductase kinase; an enzyme that catalyses the phosphorylation by ATP of [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] with release of ADP. It thereby inactivates the latter enzyme.

[hydroxymethylglutaryl-CoA reductase (NADPH)]-phos-

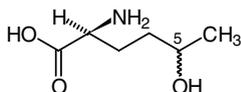

hydroxymethylglutaryl-CoA synthase

phatase EC 3.1.3.47; *other name*: reductase phosphatase; an enzyme that hydrolyses phosphate from [hydroxymethylglutaryl-CoA reductase (NADPH)] phosphate. It thereby activates the latter enzyme.

hydroxymethylglutaryl-CoA synthase *abbr.*: HMG-CoA synthase; EC 4.1.3.5; *systematic name*: (S)-3-hydroxy-3-methylglutaryl-CoA acetoacetyl-CoA-lyase (CoA-acetylating). A mostly hepatic enzyme that catalyses the reaction:

5-hydroxynorleucine *an older name (no longer recommended) for 2-amino-5-hydroxyhexanoic acid*; a non-protein (non-coded) amino acid found in plants, e.g. *Crotalaria juncea*.

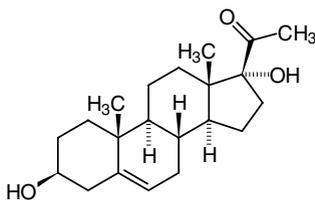

(R)-4-hydroxyphenyllactate dehydrogenase EC 1.1.1.222; *other name*: (R)-aromatic lactate dehydrogenase; an enzyme that catalyses the reaction:

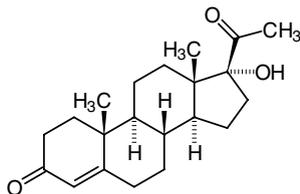

hydroxyphenylpyruvate reductase EC 1.1.1.237; an enzyme that catalyses the reaction:

17 α -hydroxypregnenolone 3 β ,17-dihydroxy-5-en-20-one; an intermediate in the synthesis of androgens, estrogens, and glucocorticoid hormones from cholesterol in the adrenal cortex. It is formed from **pregnenolone** by steroid 17 α -monooxygenase (EC 1.14.99.9).

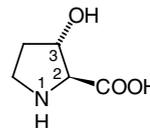

17 α -hydroxyprogesterone 17-hydroxypregn-4-one; an intermediate in the synthesis of androgens, estrogens, and glucocorticoid hormones from cholesterol in the adrenal cortex. It is formed from **progesterone** by steroid 17 α -monooxygenase (EC 1.14.99.9).

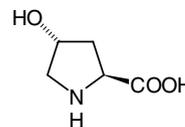

hydroxyproline *symbol*: Hyp or (formerly) Hypro; either of the two constitutional isomers 3-hydroxyproline and 4-hydroxyproline, HO-(C₄H₆NH)-COOH, both of which are chiral cyclic N-alkylated α -amino acids. Each constitutional isomer possesses two chiral centres; each can therefore exist as an enantiomeric (D and L) pair of each of two (*cis* and *trans*) diastereoisomers, making eight possible isomeric structures for hydroxyproline in all. Both *trans*-3-hydroxy-L-proline (*symbol*: 3Hyp or Pro(3-OH)), (2S,3S)-3-hydroxy-

3 β -hydroxysteroid dehydrogenase

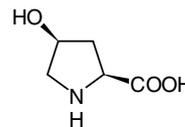

pyrrolidine-2-carboxylic acid, and *trans*-4-hydroxy-L-proline (*symbol*: 4Hyp or Pro(4-OH)), (2S,4R)-4-hydroxypyrrolidine-2-carboxylic acid, are **noncoded amino acids** found in peptide linkage in proteins. In collagen, nearly 50% of the proline residues are hydroxylated to 4Hyp, and a small proportion to 3Hyp; hydroxyproline residues are also found in elastin, enamel of the teeth, in the C1a moiety of the C1 component of **complement**, and in **extensin**. In collagen formation, enzymic hydroxylation of proline residues occurs while the growing peptide chains are still attached to ribosomes. Residues of both the *cis*-(2S,3R)- and the *trans*-(2S,3S)-isomers of 3-hydroxy-L-proline, one of each per molecule, occur in the peptide antibiotic telomycin. One residue per molecule of *cis*-4-hydroxy-L-proline, the (2S,4S)-isomer, occurs in every member of the **amatoxin** group of toxic fungal octapeptides. None of the D series of isomers is known to occur naturally.

trans-(2S,3S)-3-hydroxy-L-proline

trans-(2S,4R)-4-hydroxy-L-proline

cis-(2S,4S)-4-hydroxy-L-proline

hydroxyprolinemia or **hyperhydroxyprolinemia** a metabolic disorder of humans characterized by high levels of free 4-hydroxyproline in the blood plasma and urine. It is of no clinical consequence and is probably due to a deficiency in the activity of so-called hydroxyproline oxidase, i.e. the enzyme 4-oxoproline reductase (EC 1.1.1.104).

hydroxyproline-rich glycoproteins *abbr.*: HPRG; one of the four major types of **plant cell-wall proteins**. The best studied example is **extensin**, which is extensively glycosylated and forms a polypeptide type of rodlike structure.

15-hydroxyprostaglandin dehydrogenase (NAD⁺) EC 1.1.1.141; an enzyme involved in the inactivation of prostaglandins E₂, F_{2 α} , and B₁, by oxidizing the 15-hydroxyl group to a keto group. It catalyses a reaction between (5Z,13E)-(15S)-11 α ,15-dihydroxy-9-oxoprost-5,13-dienoate and NAD⁺ to form (5Z,13E)-11 α -hydroxy-9,15-dioxoprost-5,13-dienoate (15-keto PGE₂) and NADH.

3 β -hydroxysteroid dehydrogenase an enzyme that converts the 3 β -OH group of the substrate to a 3-keto group and isomerizes the C5,6 double bond to the C4,5 position in the following reactions on C₂₁ and C₁₉ steroids:

- (1) pregnenolone + NAD⁺ = progesterone + NADH;
- (2) 17-hydroxypregnenolone + NAD⁺ = 17-hydroxyprogesterone + NADH;
- (3) dehydroepiandrosterone + NAD⁺ = androstenedione + NADH.

It is the only steroidogenic enzyme of the endoplasmic reticulum

that is not a cytochrome P450. In humans, two genes at 1p13 result in two isozymes: type 1 is expressed in nonsteroidogenic tissues, e.g. liver, breast, prostate, and skin; type 2 is expressed in steroidogenic tissues, i.e. adrenal cortex and gonads. Mutations in the gene for the type 2 isozyme are a rare cause of a salt-losing congenital adrenal hyperplasia in which there is deficiency of aldosterone, cortisol, and adrenal androgens (the three final products of the above reactions, respectively).

17 β -hydroxysteroid oxidoreductase an enzyme of the endoplasmic reticulum that catalyses the reaction:

There are three homologous human isozymes of which type 3 (gene locus at 9q22) is expressed predominantly in the testes. Inactivating mutations in this gene result in enzyme deficiency, which leads to testosterone deficiency and male pseudohermaphroditism.

3 β -hydroxysteroid- Δ^5 -oxidoreductase/isomerase an enzyme of liver and fibroblasts that catalyses the reaction:

It differs from the **3 β -hydroxysteroid dehydrogenase**, for which the substrates are C₂₁ and C₁₉ steroids. A very rare deficiency produces a syndrome of jaundice, hepatosplenomegaly, pale stools, and dark urine (from abnormal bile acid excretion). If untreated the condition progresses to hepatic cirrhosis.

N-hydroxysuccinimide ester or **NHS ester** any compound in which N-hydroxysuccinimide (NHS) has reacted with a carboxy group to form an ester. NHS esters react under mild conditions (>pH 7) with primary amino groups such as those at the N-terminus of proteins or ϵ -amino groups of lysine to form amide bonds with the release of NHS. NHS esters are used for labelling proteins with fluorescent tags or for crosslinking two molecules (often proteins) by covalent bonds.

5-hydroxytryptamine *abbr.*: 5-HT; *an alternative name for serotonin.*

5-hydroxytryptamine receptor any membrane protein that binds 5-hydroxytryptamine (i.e. **serotonin**) and mediates its intracellular effects. The receptors belong to seven families. Members of the 5-HT₁ family are G-protein-associated receptors and inhibit adenylate cyclase, but the 5-HT_{1A} receptor also increases K⁺ conductance. Those of the 5-HT₂ family are G-protein-associated receptors and stimulate phospholipase C. 5-HT₃ opens a Cl⁻ channel; 5-HT₄ has four transmembrane segments and activates adenylate cyclase; 5-HT₅ is G-protein-associated but its effector is unknown. 5-HT₆ and 5-HT₇ are G-protein-associated receptors that activate adenylate cyclase.

5-hydroxytryptophan a non-protein amino acid found in plants; it is formed in legumes by hydroxylation of tryptophan. It is also formed in animals. *See also serotonin.*

hydroxyurea NH₂CONHOH; an analogue of **urea** with antineoplastic activity, possibly through inhibition of DNA synthesis.

hygro+ *comb. form* denoting moisture, especially that due to water.

hygrometer any instrument for measuring the relative humidity of a gas.

hygromycin B an aminoglycoside antibiotic from *Streptomyces hygroscopicus*. It kills bacterial, fungal, and higher eukaryotic cells by inhibiting protein synthesis. The inclusion of genes conferring resistance to hygromycin B in certain fungal recombinant DNA vectors allows selection of recombinants when these are plated out on medium containing this antibiotic.

hygromycin B phosphotransferase an enzyme from *Streptomyces hygroscopicus* that confers resistance to the toxic effects of hygromycin B. It is used as a dominant selectable marker in eukaryotic cells transfected with DNA constructs that incorporate the gene.

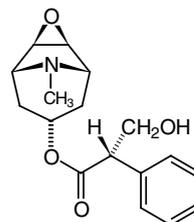

hygroscopic (*of a substance*) tending to absorb water from the surrounding atmosphere. *Compare deliquescent.*

Hyl or (*formerly*) **Hyls** *symbol* for a residue of any of the hydroxy derivatives of the α -amino acid L-lysine, especially 5-hydroxy-L-lysine. *See hydroxylysine.*

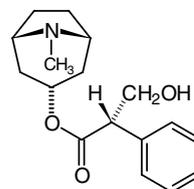

5Hyl *symbol* for a residue of the α -amino acid 5-hydroxy-L-lysine (*preferred alternative* to Lys(5-OH) or Hyl). *See hydroxylysine.*

Hyls *former symbol* for a residue of (5-)hydroxy-L-lysine (5Hyl or Hyl now recommended).

hyoscine or **scopolamine** an alkaloid found, e.g., in *Datura stramonium* (thorn apple) and related to **atropine** in its structure and effects; it is a tertiary ammonium compound noted for its actions as a **muscarinic receptor** antagonist. It has found use as a sedative and preanesthetic and for prevention of motion sickness.

hyoscyamine 3 α -tropanyl S(-)-tropate; an anticholinergic material obtained from *Atropa belladonna* and other plants. It undergoes partial racemization on isolation; this process is completed by alkali treatment, and the racemic mixture is known as atropine.

(-)-hyoscyamine

hyp+ *a variant form of hypo+* (*before a vowel*).

Hyp 1 or (*formerly*) **Hyp_{ro}** *symbol* for a residue of either the 3-hydroxy or the 4-hydroxy derivative of the α -amino (strictly, α -imino) acid L-proline, usually 4-hydroxy-L-proline. *See hydroxyproline. See also 3Hyp, 4Hyp. 2 symbol* for a residue of the purine base **hypoxanthine**.

3Hyp *symbol* for a residue of the α -amino acid 3-hydroxy-L-proline (*preferred alternative* to Pro(3-OH) or Hyp). *See hydroxyproline.*

4Hyp *symbol* for a residue of the α -amino acid 4-hydroxy-L-proline (*preferred alternative* to Pro(4-OH) or Hyp). *See hydroxyproline.*

hyperclicin A a 20-residue peptide of microbial origin containing 10 α -aminoisobutyric acid residues. The N terminus is acylated and the C terminus amidated with **leucinol**. It modifies the permeability of phospholipid bilayers.

hypert+ *prefix* indicating over, beyond, excessive, or in excess; above the normal range. *Compare hypo+, normo+.*

hyperaldosteronism an elevated level of **aldosterone** in the blood. In primary aldosteronism, there is overproduction of aldosterone due to an adrenal tumour, as in Conn's syndrome or hyperplasia of the zona glomerulosa. In secondary aldosteronism the overproduction is caused by excessive levels of stimulatory hormones, especially increased renin secretion.

hyperammonemia or (*esp. Brit.*) **hyperammonaemia** the presence of excess ammonia in the blood (the normal range is 10–47 $\mu\text{mol L}^{-1}$). It occurs in inherited disorders of the urea cycle, organic acidemias, liver disease, and severe systemic illness. It is accompanied by cerebral edema with clouding of consciousness that may lead to coma and death. In these conditions it may be precipitated or aggravated by high protein intake. *See also ornithine-urea cycle.*

hyperbaric of, relating to, or operating at higher than normal pressures.

hyperbilirubinemia or (*esp. Brit.*) **hyperbilirubinaemia** the presence of higher than normal concentrations of **bilirubin** in the blood;

it may involve unconjugated or conjugated bilirubin. It occurs in liver disease or biliary obstruction, and is characteristic of neonatal hemolytic **jaundice**, where the bilirubin is mainly unconjugated. — **hyperbilirubinemic** or **hyperbilirubinaemic** *adj.*

hyperbola one of the conic sections; a plane curve in which the focal distance of any point bears to its distance from the directrix a constant ratio greater than unity. It has two foci and two asymptotes. *Compare* **rectangular hyperbola**. — **hyperbolic** *adj.*

hyperbolic function any one of a group of functions of an angle, analogous to the trigonometric functions, expressed as a relationship between the distances of a point on a hyperbola to the origin and to the coordinate axes. The group includes **sinh** (hyperbolic sine), defined as $\sinh x = (e^x - e^{-x})/2$; **cosh** (hyperbolic cosine), defined as $\cosh x = (e^x + e^{-x})/2$; and **tanh** (hyperbolic tangent), defined as $\tanh x = (\sinh x)/(\cosh x)$. The corresponding reciprocal functions are **cosech** (hyperbolic cosecant), **sech** (hyperbolic secant), and **coth** (hyperbolic cotangent), respectively.

hyperbolic kinetics curve a description sometimes used of the $v/[S]$ plot obtained for enzymes exhibiting **Michaelis–Menten kinetics**. The axes of the plot are not those of the rectangular hyperbola that results, but are rotated 45° (and displaced) from the true axes of the hyperbola.

hypercalcaemia or (*esp. Brit.*) **hypercalcaemia** the presence of higher than normal concentrations of **calcium** in the blood. Clinical features include tiredness, muscle weakness, anorexia, weight loss, cardiac arrhythmia, and hypertension. It arises from a multiplicity of causes including malignancy, primary hyperparathyroidism, hyperthyroidism, acute adrenal insufficiency, familial hypocalcaemic hypercalcaemia, vitamin D or A overdose, or sarcoidosis. — **hypercalcaemic** or **hypercalcaemic** *adj.*

hypercapnia or **hypercarbia** the presence of greater than normal amounts of carbon dioxide in a vertebrate or in its blood. *Compare* **hypocapnia**. — **hypercapnic** or **hypercarbic** *adj.*

hyperchlorhydria the presence of greater than normal amounts of hydrochloric acid in the gastric juice. — **hyperchlorhydric** *adj.*

hypercholesterolemia or (*esp. Brit.*) **hypercholesterolaemia** the presence of higher than normal concentrations of cholesterol in the blood. *See also* **hyperlipidemia**. — **hypercholesterolemic** or **hypercholesterolaemic** *adj.*

hyperchromatic **1** of, relating to, or exhibiting **hyperchromatism**. **2** an alternative word for **hyperchromic** (def. 1).

hyperchromatism the condition or property (of a cell or cell organelle) of staining more intensely than normal; the presence of a greater than normal amount of chromatin.

hyperchromic **1** or **hyperchromatic** more highly coloured than normal; intensely coloured. **2** of, pertaining to, exhibiting, or resulting from **hyperchromism**. **3** (of a substance) displaying a **hyperchromic effect**. **4** describing erythrocytes that contain, or appear to contain, more hemoglobin than normal.

hyperchromic effect the large increase in absorption of ultraviolet light, usually measured at 260 nm, shown by a solution of any natural or synthetic polynucleotide with a hydrogen-bonded structure when it is denatured or degraded. The effect is due to alterations in the electronic interactions between the initially stacked and hydrogen-bonded bases.

hyperchromicity a measure of the increase in absorption of electromagnetic radiation at a specific wavelength, usually that of the absorption maximum, due to **hyperchromism**, or to the **hyperchromic effect**. It is equal to the reciprocal of the **hypochromicity** minus unity.

hyperchromism the increased absorption of electromagnetic radiation exhibited by an ordered structure above that predicted on the basis of its constitution.

hyperfine splitting the splitting of a spectral line into multiplets of closely spaced lines. In electron spin resonance spectra hyperfine splitting is due to the interaction of unpaired electrons with neighbouring nuclei and can be used to determine the structure of a free radical or to identify the ligands of a paramagnetic ion and to measure the degree of covalent binding that exists between them. In nuclear magnetic resonance spectra, hyperfine splitting, sometimes called **spin–spin splitting**, is due to the interaction of the nuclear magnetic moment with those of neighbouring nuclei and can be

used to assign particular nuclear resonances and to determine molecular conformations.

hyperfine structure the presence in a spectrum of multiplets of closely spaced lines resulting from **hyperfine splitting**.

hyperforin the major active ingredient of the herb St John's wort, which is used as an herbal in a variety of ailments. It binds to a transcription factor (pregnane X receptor) and enhances expression of cytochrome P4503A4, which degrades certain drugs (e.g. cyclosporin and the HIV protease inhibitor indinavir).

hyperglycemia or (*esp. Brit.*) **hyperglycaemia** an abnormally high blood glucose concentration, especially in relation to the fasting value. *See also* **glycemia**. — **hyperglycemic** or **hyperglycaemic** *adj.*

hyperglycemic factor or **hyperglycemic-glycogenolytic factor** a former name for **glucagon**.

hyperhydroxyprolinemia *see* **hydroxyprolinemia**.

hyper-IgD syndrome *abbr.*: HIDS; a rare autosomal recessive disease in which recurrent bouts of fever are associated with increased plasma levels of IgD and mevalonic aciduria. Activity of the enzyme mevalonate kinase is 5–15% of normal.

hyper-IgM syndrome a condition in which recurrent respiratory infections in early childhood are associated with very low concentrations of IgG, IgA, and IgE but normal or elevated concentrations of IgM in serum. It may be due to X-linked and autosomal recessive traits. *See* **activation-induced cytidine deaminase**.

hyperimmune describing the state of an animal in which very high concentrations of specific antibody are present in the serum, brought about by **hyperimmunization**.

hyperimmunization or **hyperimmunisation** any method of immunization designed to stimulate the production in the animal immunized of very large quantities of specific antibody. It typically involves the repeated administration of immunogen, often in increasing amounts.

hyperinsulinemia syndrome or (metabolic) **syndrome X** a syndrome of impaired glucose tolerance, fasting hyperinsulinemia, hypertriglyceridemia, hypertension, and increased predisposition to atherosclerosis. If untreated it often leads to diabetes mellitus type 2. *See* **insulin resistance**.

hyperkalemia or (*esp. Brit.*) **hyperkalaemia** the presence in the blood of an abnormally high concentration of **potassium**. There are many causes including excessive K⁺ intake (infusion, transfusion), increased transcellular movement (tissue damage, systemic acidosis), and decreased K⁺ loss (renal failure, mineralocorticoid deficiency). — **hyperkalemic** or **hyperkalaemic** *adj.*

hyperlactatemia or (*esp. Brit.*) **hyperlactataemia** a persistent raised blood lactate concentration, usually below 5 mmol L⁻¹, and not accompanied by a lowered blood pH. The normal range is between 0.5 and 2.2 mmol L⁻¹. *Compare* **lactic acidosis**. — **hyperlactatemic** or **hyperlactataemic** *adj.*

hyperlipidemia or **hyperlipemia** or (*esp. Brit.*) **hyperlipidaemia** or **hyperlipaemia** the presence in the blood of an abnormally high concentration of fats (or lipids). Hyperlipidemias have been classified into various types according to which lipoprotein class is found to be elevated in the blood. The Fredrickson classification scheme designates: type I, elevated chylomicrons; type II, elevated low-density lipoprotein; type III, elevated intermediate-density lipoprotein; type IV, elevated very-low-density lipoprotein; type V, elevated chylomicrons and very-low-density lipoprotein. A simpler distinction, of use in treatment, is between elevated cholesterol levels (type II, **hypercholesterolemia**) and elevated triacylglycerol levels (types I, III–V, **hypertriglyceridemia**, an older term still often used). Hyperlipidemia may be secondary to other conditions; several drugs cause or exacerbate hyperlipidemia, including thiazides, **beta blockers** lacking intrinsic sympathomimetic activity, and **corticosteroids**. Estrogens may lower hypercholesterolemia, but may cause or exacerbate hypertriglyceridemia; hypothyroidism is commonly associated with hypercholesterolemia; high alcohol intake causes hypertriglyceridemia, but modest alcohol intake may have a beneficial effect on cholesterol status, as it tends to increase **high-density lipoprotein** concentration. — **hyperlipidemic**, **hyperlipemic** or **hyperlipidaemic**, **hyperlipaemic** *adj.*

hypermodified base any extensively modified nucleic-acid base occurring adjacent to the 3' end of the anticodon in many tRNA

molecules. Examples are N^6 -(δ -isopentenyl)adenosine (*symbol*: iA) and N^6 -(threonylcarbamoyl)adenosine (*symbol*: tA). Hypermodified bases are thought to be important for proper binding of tRNA molecules to ribosomes.

hypernatremia or (*esp. Brit.*) **hypernatraemia** the presence in the blood of an abnormally high concentration of sodium. It may be associated with conditions in which body water is depleted. —**hypernatremic** or **hypernatraemic** *adj.*

hyperornithinemia *see* **OAT**.

hyperoxaluria the presence of oxalate in the urine in abnormally high amounts. It is associated with the formation of renal calculi. Type 1, the commonest, results from overproduction of oxalate from glyoxylate because of deficiency of alanine-glyoxylate aminotransferase (EC 2.4.1.44) activity. Type 2 results from deficiency of D-glycerate dehydrogenase/glyoxylate reductase (EC 1.1.1.29). Type 3 results from a poorly characterized increased absorption of oxalate from the intestine.

hyperoxia the presence of greater than normal amounts of dioxygen in a vertebrate or in its blood. *Compare* **hypoxia**. —**hyperoxic** *adj.*

hyperparathyroidism the increased production of **parathyroid hormone**. It may be primary, as a result of a tumour of the parathyroid gland, or secondary, as a result of a disturbance in calcium metabolism.

hyperphosphatemia or (*esp. Brit.*) **hyperphosphataemia** an excessive level of phosphate in the blood. It occurs most commonly in renal insufficiency, but may also accompany hypoparathyroidism, vitamin D intoxication, or excessive administration of phosphate. —**hyperphosphatemic** or **hyperphosphataemic** *adj.*

hyperplasia the increase in size of a tissue or organ resulting from an increase in the total number of cells present. The part thus affected retains its normal form. *Compare* **hypertrophy**. —**hyperplastic** *adj.*

hyperprolactinemia or (*esp. Brit.*) **hyperprolactinaemia** the presence in the blood of abnormally high levels of **prolactin**, due to excessive secretion of the hormone. The most common example of pituitary hyperfunction, it results from pituitary adenoma, and also from treatment with dopamine receptor blockers. It can be treated with dopamine agonists, e.g. **bromocriptine**. —**hyperprolactinemic** or **hyperprolactinaemic** *adj.*

hypersecretion excessive secretion by any endocrine or exocrine gland.

hypersensitive having an abnormally great sensitivity, especially to an allergen, drug, or other agonist.

hypersensitive sites regions of chromatin that are unprotected by histones and other DNA-binding proteins and are sites of active transcription in the genome. The presence of such sites is revealed by treating intact nuclei with DNase I and analysing the resulting fragments of DNA.

hypersensitivity 1 the state or condition of being **hypersensitive**. **2** (*in immunology*) an immune response that occurs in an exaggerated or inappropriate form. Such responses may result from agents including pollen or drugs, or from genuine pathogens. Also of importance are the different kinds of tissue damage seen in autoimmune diseases. In general terms the reactions may be classified into four types, although they do not occur in isolation from each other: type I, **immediate hypersensitivity**; type II, **antibody-mediated hypersensitivity**; type III, **immune complex-mediated hypersensitivity**; and type IV, **delayed hypersensitivity**.

hypersensitivity mapping a method for identifying sites in chromatin at which active transcription is taking place. Cloning and sequencing of DNA flanking DNase I **hypersensitive sites** permits the identification of genes being transcribed.

hypersharping the formation of a 'sharper' boundary in sedimentation and moving boundary electrophoresis experiments than would be expected as a result of diffusion-broadening, because molecules in the trailing portion of the boundary tend to move at a greater velocity per unit field than molecules on the leading edge or in the plateau region.

hypertension the state or condition of having a higher than normal arterial blood pressure. —**hypertensive** *adj.*

hyperthermophile an organism growing at a temperature above

80°C. Almost all thermophiles belong to the kingdom **Archaea**.

Compare **thermophile**.

hyperthyroidism or **thyrotoxicosis** a clinical state resulting from excessive secretion of thyroid hormones. The most common cause is Graves' disease; other causes include goitre and solitary toxic adenoma. The associated nervousness, irritability, fatigue, heat intolerance, and (not in all) exophthalmia derive from exaggeration of normal responses to thyroid hormones. *See also* **thyroxine**. —**hyperthyroid** *adj.*

hypertonic 1 (*of a solution*) having a higher osmotic pressure than that of some given solution, especially that of the fluid in or surrounding a given type of cell or a body fluid. **2** (*of a muscle*) showing or characterized by excessive tone or tension. *Compare* **hypotonic**. —**hypertonicity** *n.*

hypertriglyceridemia or (*esp. Brit.*) **hypertriglyceridaemia** *see* **hyperlipidaemia**.

hypertrophy the increase in the size of a tissue or organ resulting from an increase in the size of the cells present. *Compare* **hyperplasia**. —**hypertrophic** *adj.*

hyperuricemia or (*esp. Brit.*) **hyperuricaemia** the presence of elevated amounts of uric acid in the blood. This may be due to increased purine synthesis arising from a metabolic disorder, inherited or otherwise, or to reduced excretion – e.g. renal disease, the effect of drugs (e.g. salicylates), or the presence of organic acids (e.g. lactate) that competitively inhibit urate excretion. Hyperuricemia is associated with **gout**.

hypervariable region *an alternative name for* complementarity-determining region.

hypo *a common name for* sodium thiosulfate, especially when used in photographic processing.

hypo+ or (*before a vowel*) **hyp+** *prefix* denoting under, beneath, below, less than, or in deficit; below the normal range. *Compare* **hyper+**, **normo+**.

hypoalphalipoproteinemia *see* **hypolipoproteinemia**.

hypobaric of, relating to, or operating at pressures lower than normal.

hypobetalipoproteinemia *see* **hypolipoproteinemia**.

hypocalcemia or (*esp. Brit.*) **hypocalcaemia** the presence of a lower than normal concentration of **calcium** in the blood. It may be associated with disorders of vitamin D metabolism, **hypoparathyroidism**, magnesium deficiency, or pancreatitis. Clinical features include behavioural disturbances, stupor, numbness, paresthesia, muscle cramps or spasms, and convulsions. —**hypocalcemic** or **hypocalcaemic** *adj.*

hypocapnia or **hypocarbica** the presence of less than the normal amount of carbon dioxide in a vertebrate or in its blood. *Compare* **hypercapnia**. —**hypocapnic** or **hypocarbic** *adj.*

hypochlorhydria the presence of less than the normal amount of hydrochloric acid in the gastric juice. —**hypochlorhydric** *adj.*

hypochlorous acid HOCl; a strong oxidizing and halogenating agent and bactericide, used as the active ingredient of bleach. It is generated by the enzyme **myeloperoxidase** in azurophilic granules of neutrophils and lysosomes of monocytes, in response to the entry of bacteria.

hypcholesterolemia or (*esp. Brit.*) **hypcholesterolaemia** the presence of a lower than normal concentration of cholesterol in the blood. —**hypcholesterolemic** or **hypcholesterolaemic** *adj.*

hypochondroplasia *see* **achondroplasia**.

hypochromatic 1 of, relating to, or exhibiting **hypochromatism**. **2** *an alternative word for* **hypochromic** (def. 1).

hypochromatism the condition or property (of a cell or cell organelle) of staining less intensely than normal; the presence of an abnormally low amount of chromatin.

hypochromic 1 or **hypochromatic** less highly coloured than normal; weakly coloured. **2** of, pertaining to, exhibiting, or resulting from **hypochromism**. **3** (*of a substance*) displaying a **hypochromic effect**. **4** describing erythrocytes that contain, or appear to contain, less hemoglobin than normal.

hypochromic effect the observed decrease in absorption of certain frequencies of electromagnetic radiation by solutions of some macromolecules when the structure of the molecules becomes more ordered.

hypochromicity a measure of the decrease in absorption of electromagnetic radiation at a specific wavelength, usually that of the absorption maximum, due to **hypochromism**.

hypochromism the decreased absorption of electromagnetic radiation exhibited by an ordered structure below that predicted on the basis of its constitution.

hypocretin or **orexin** either of two polypeptides (of 39 and 29 amino acids) that occur in the lateral hypothalamus and increase food intake. They arise from the same precursor by differential cleavage and act on G-protein-coupled membrane receptors that regulate feeding behaviour.

hypoglycemia or (*esp. Brit.*) **hypoglycaemia** the presence of an abnormally low blood glucose concentration, especially in relation to the fasting value. *See also* **glycemia**. —**hypoglycemic** or **hypoglycaemic** *adj.*

hypoglycin or **hypoglycine** β -(methylenecyclopropyl)alanine; 2-amino-3-(methylenecyclopropane)propanoic acid. A nonprotein α -amino acid identified as the hypoglycemic and toxic principle of the unripe fruit of the **ackee** (*Blighia sapida*), where it is present both in the fleshy aril and in the seeds. In the latter it occurs also as the *N*-L-glutamyl derivative, **hypoglycin B**. Certain other fruits also contain hypoglycin. It is degraded in animals to methylenecyclopropylacetate, either free or conjugated to glycine or coenzyme A. Methylenecyclopropylacetyl-CoA is a potent and specific inhibitor of the oxidation of short-chain acyl-CoAs, particularly of butyryl-CoA and glutaryl-CoA. In hypoglycin poisoning butyrate and glutarate accumulate in the blood and lead to metabolic acidosis and excessive urinary excretion of these compounds. *See also* **Jamaican vomiting sickness**.

Hyp(3-OH) *symbol* for a residue of the α -amino acid 3-hydroxy-L-proline (alternative to 3Hyp or Hyp). *See* **hydroxyproline**.

Hyp(4-OH) *symbol* for a residue of the α -amino acid 4-hydroxy-L-proline (alternative to 4Hyp or Hyp). *See* **hydroxyproline**.

hypokalemia or (*esp. Brit.*) **hypokalaemia** the presence in the blood of an abnormally low concentration of potassium. It may result from alkalosis, insulin administration, primary or secondary aldosteronism, or administration of drugs that are aldosterone antagonists. —**hypokalemic** or **hypokalaemic** *adj.*

hypolipoproteinemia the partial or total absence of any lipoprotein, or the presence of a defective lipoprotein, in the plasma. Several types of this condition are recognized. **Hypobetalipoproteinemia** is arbitrarily defined as a low-density lipoprotein (LDL) cholesterol level below the fifth percentile for a given sex- and age-matched population. Such patients also have low triacylglycerol levels. In this condition, LDL cholesterol is always detectable, in contrast to homozygous **abetalipoproteinemia**, in which it is entirely absent. Hypobetalipoproteinemia appears to be due to a low rate of synthesis of LDL from very-low-density lipoprotein. Abetalipoproteinemia is a rare autosomal recessive disorder. It probably results from an abnormality in the synthesis or secretion of apo B, and it is accompanied by fat malabsorption, as chylomicron formation requires apo B. In the homozygote, levels of triacylglycerols, cholesterol, and phospholipids are extremely low. Heterozygotes may present with hypobetalipoproteinemia. **Hypoalphalipoproteinemia** is in some cases familial, and may result from defective apo A-I. In another disorder, known as fish-eye disease (due to severe corneal opacity), the structure of apo A-I is normal, but high-density lipoprotein (HDL) levels are only 10% of normal. In analphalipoproteinemia, or **Tangier disease**, HDL is virtually absent.

hyponatremia or (*esp. Brit.*) **hyponatraemia** the presence in the blood of an abnormally low concentration of sodium. It can occur as a result of incorrect administration of fluid intravenously or in parenteral feeding, after administration of diuretics, in congestive heart failure, or in protein imbalance. —**hyponatremic** or **hyponatraemic** *adj.*

hypoparathyroidism underactivity of the **parathyroid glands**.

hypophase the lower layer of a two-phase system. *Compare* **epiphase**. —**hypophasic** *adj.*

hypophosphatasia *see* **alkaline phosphatase**.

hypophosphatemia or (*esp. Brit.*) **hypophosphataemia** the presence of an abnormally low level of phosphate in the blood. It occurs in vitamin D deficiency, primary **hyperparathyroidism**, incorrect par-

enteral nutrition, during recovery from diabetic ketoacidosis, and in hereditary defects of uptake of renal phosphate. *See* **fibroblast growth factor-23**, **PHEX**.

hypophysectomy surgical removal of the pituitary gland (i.e. hypophysis). —**hypophysectomize** or **hypophysectomise** *vb.*

hypophysiotropic factor or **hypophysiotropic hormone** *an alternative name for* **hypothalamic (regulatory) factor**.

hypophysis or **hypophysis cerebri** *an alternative name for* **pituitary gland**. *See also* **adenohypophysis**, **neurohypophysis**. —**hypophyseal** or **hypophysial** *adj.*

hypopituitarism total or (more often) partial loss of pituitary function, usually due to destructive lesions of the pituitary.

hypoplasia underdevelopment or defective formation of an organ or tissue. —**hypoplastic** *adj.*

hypoprothrombinemia or (*esp. Brit.*) **hypoprothrombinaemia** an abnormally low (inadequate) level of plasma prothrombin (factor II), commonly caused by vitamin K deficiency.

hyposecretion lesser than normal secretion by any endocrine or exocrine gland.

hypotension the state or condition of having a lower than normal arterial blood pressure. —**hypotensive** *adj.*

hypothalamic (regulatory) factor or **hypothalamic hormone** or **hypophysiotropic factor** or **hypophysiotropic hormone** any peptidic substance that is synthesized in the mammalian hypothalamus and released into the hypophyseal-portal circulation in response to neural and/or chemical stimuli, and that regulates the secretion (and perhaps also the synthesis) of a specific polypeptide hormone by the anterior lobe of the pituitary gland (i.e. adenohypophysis). These specific factors may be either releasing or release-inhibiting factors (or hormones); their recommended names are now formed by replacing the word-ending 'tropin' (or '-in' in prolactin) in the name of the corresponding pituitary hormone by the word-ending '-liberin' (for a releasing factor) or '-statin' (for a release-inhibiting factor).

hypothalamus (*pl.* **hypothalami**) the region of the vertebrate brain lying below the thalamus and around the floor of the third ventricle, just posterior to the attachment of the cerebral hemispheres. It lies just above the **pituitary gland**, to which it supplies various **hypothalamic (regulatory) factors**. —**hypothalamic** *adj.*

hypothetical protein a translation product that cannot be related (e.g. by means of database similarity searches) to any previously characterized protein.

hypothyroidism deficient secretion by the thyroid gland. In infants it leads to cretinism; in adults the consequences include low metabolic rate, lethargy, menstrual disorders, and in extreme cases **myxedema**. —**hypothyroid** *adj.*

hypotonic 1 (of a solution) having a lower osmotic pressure than that of some given solution, particularly the fluid in or surrounding a given type of cell or a body fluid. **2** (of a muscle) showing or characterized by diminished tone or tension. *Compare* **hypertonic**. —**hypotonicity** *n.*

hypovolemia or (*esp. Brit.*) **hypovolaemia** a reduction in the volume of circulating blood. It may be due to hemorrhage or to redistribution of fluid from the plasma to the extravascular tissues and spaces.

hypox *abbr.* for hypophysectomized. *See* **hypophysectomy**.

hypoxanthine *symbol:* Hyp; purin-6(1*H*)-one; 6-hydroxy purine; an intermediate in the degradation of adenylate. Its ribonucleoside is known as **inosine** and its ribonucleotide as **inosinate**. *Compare* **xanthine**. *See also* **hypoxanthine phosphoribosyltransferase**.

hypoxanthine/guanine phosphoribosyltransferase *abbr.:* HGPRT; *see* **hypoxanthine phosphoribosyltransferase**.

hypoxanthine phosphoribosyltransferase EC 2.4.2.8; *systematic name:* IMP:pyrophosphate phospho-D-ribose transferase; *other names:* hypoxanthine/guanine phosphoribosyltransferase (*abbr.:* HGPRT); IMP pyrophosphorylase. An enzyme that catalyses a reaction between 5-phospho- α -D-ribose 1-diphosphate and either hypoxanthine or guanine to form IMP or GMP respectively, with release of pyrophosphate. It is important for the metabolic activation of purines, e.g. 6-mercaptopurine, and forms part of the purine salvage pathway. Partial deficiency is associated with **Lesch-Nyhan syndrome** and **gout**.

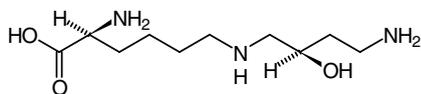

hypoxia the presence of less than normal amounts of dioxygen in a vertebrate or in its blood. *See* ARNT, HIF. *Compare* hyperoxia. —*hypoxic* *adj.*

hypoxia-inducible factor *See* HIF.

Hypo (*formerly*) *symbol* for a residue of (4-)hydroxy-L-proline (4Hyp or Hyp now recommended).

hypsochromic describing the shift of an absorption band in the direction of shorter wavelengths. *Compare* bathochromic.

hypusine *N*^ε-[4-amino-2-hydroxybutyl]lysine; an amino acid uniquely formed by post-translational modification of one of the lysyl residues of eukaryotic translation initiation factor 5A (eIF-5A). It is formed by deoxyhypusine synthase, an enzyme that transfers the butylamine portion of spermidine to the ε-NH₂ group of a specific lysine of the eIF-5A precursor, followed by addition of the hydroxyl group by deoxyhypusine hydroxylase.

hysteresis the delay between the effect on a system and the cause producing the effect. —*hysteretic* *adj.*

hysteretic enzyme any enzyme that responds slowly (in terms of some kinetic characteristic) to a rapid change in ligand (either substrate or modifier) concentration. Such slow changes, defined in terms of their rates relative to the overall catalytic reaction, result in a lag in the response of the enzyme to changes in the ligand level.

Hz *symbol* for hertz.

H zone *see* sarcomere.

i *symbol for* **I** iso (def. 3); (as a prefix or superscript in symbols and abbreviations for iso compounds or groups; e.g. isopropyl can be symbolized as iPr or Prⁱ). **2** the chemical group 2-isopentenyl; 3,3-dimethylallyl (as a prefix to a single-letter symbol for a nucleoside residue to designate substitution of the base, as in **iA**). **3** the square root of -1 .

i *symbol for* **I** electric current (alternative to *I*). **2** van't Hoff factor.

I *symbol for* **I** iodine. **2** an iodo group in an organic compound. **3** a residue of the α -amino acid L-isoleucine (alternative to Ile). **4** a residue of the ribonucleoside inosine (alternative to Ino).

I *symbol for* **I** electric current (preferred alternative to *i*). **2** intensity; the subscripts e (for energetic), p (for photon), or v (for visible) may be added to distinguish between radiant intensity, photon intensity, and luminous intensity, respectively. **3** ionic strength; the subscripts c or m may be added to indicate whether it is expressed based on concentration or molality respectively. **4** the inductive effect of a particular chemical group in an organic compound.

iA *symbol for* N⁶-(2-isopentenyl)adenosine, a **hypermodified base**.

IAA *abbr. for* indole-3-acetic acid *or* **indoleacetate**.

IAN *abbr. for* indoleacetoneitrile.

IAP *abbr. for* **I** islet-activating protein; *see* **pertussis toxin**. **2** inhibitor of apoptosis protein; *other name*: apoptosis inhibitory protein (*abbr.*: AIP); any of a group of proteins that inhibit apoptosis. They bind tumour necrosis factor (TNF) receptor-associated proteins 1 and 2. Mutations in a neuronal IAP (*abbr.*: NIAP), a 294-residue protein encoded at 5q12.2-q13.3, cause various forms of spinal muscular atrophy. *See* **TNF receptor-associated protein 2**.

iatrogenic describing a condition or disease induced unintentionally by a physician through his or her diagnosis, manner, or therapy. —**iatrogenicity** *n*.

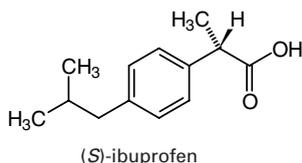

IκB *abbr. for* inhibitor of NF-κB; a cytosolic protein that binds and inhibits **NF-κB** in most cell types. It is released from binding following phosphorylation by the **IκB kinase** complex in response to binding of tumour necrosis factor α and interleukin-1 to their receptors. The phosphorylation targets IκB for ubiquitination and degradation by proteasomes.

I-band *abbr. for* isotropic band. The I-bands of striated muscle contain the **thin filaments** and correspond to the light bands. The name derives from the fact that they are isotropic in polarized light. *See also* **sarcomere**.

IκB kinase a heterotrimeric complex (≈ 700 kDa) that acts on **IκB** to release NF-κB and target IκB for ubiquitination and degradation by proteasomes. It consists of two catalytic subunits (α and β), which share $\approx 50\%$ sequence identity, and a regulatory subunit (γ). It is activated by phosphorylation via multiple signalling pathways, including tumour necrosis factor α and interleukin-1.

IBMX *abbr. for* isobutylmethylxanthine.

ibuprofen 2-(4-isobutylphenyl)propionic acid; a nonsteroidal anti-inflammatory agent of the substituted propionic acid type; others of this type are flurbiprofen, **ketoprofen**, and naproxen. They inhibit the cyclooxygenase activity of **prostaglandin-endoperoxide synthase**, reversibly over short time intervals, followed by time-dependent irreversible inactivation, due probably to conformational rather than covalent changes. The racemic mixture is present in many over-the-counter drugs, but the (*S*)-enantiomer is the active form. *Proprietary names include*: Advil; Brufen; Motrin.

ic *or* **i.c.** *abbr. for* intracutaneous or intracutaneously.

IC *abbr. for* internal conversion.

IC₅₀ **1** the median inhibitory concentration (in mol L⁻¹) of an antagonist, i.e. the concentration that reduces a specified response to 50% of its former value; *compare* **EC₅₀**. **2** the median inhibitory concentration (in mol L⁻¹) of an agent (agonist or antagonist), i.e. the concentration that causes a 50% reduction in the specific binding of a radioligand.

ICAM *abbr. for* intercellular adhesion molecule; any of several type I membrane glycoproteins of the immunoglobulin superfamily. They are ligands for leukocyte adhesion to target cells, in conjunction with **LFA-1**; in fact LFA-1–ICAM links mediate adhesion between many cell types. **ICAM-1** (*or* CD54), of 90–115 kDa, are expressed on B and T lymphocytes, endothelial, epithelial, and dendritic cells, fibroblasts, keratinocytes, and chondrocytes. They are inducible in 12–24 hours by cytokines such as gamma interferon, interleukin-1 β , and tumour necrosis factor- α . **ICAM-2** (*or* CD102), of 55–65 kDa, are constitutively expressed on endothelial cells, some lymphocytes, monocytes, and dendritic cells. **ICAM-3** (*or* CD50), of 116–140 kDa, are constitutively expressed on monocytes, granulocytes, and lymphocytes; and on stimulation are rapidly and transiently phosphorylated on serine residues.

ICAT *abbr. for* **isotopically coded affinity tag**.

ICD (*in clinical chemistry*) *abbr. for* isocitrate dehydrogenase (EC 1.1.1.41).

ice the solid form of water that can exist at temperatures below the triple point of water (273.16 K at 101 325 Pa).

ICE *abbr. for* **I** imprint control element; a CpG rich region of genomic DNA that attracts *de novo* methylation in one parental gamete and avoids methylation in the other parental gamete. It is necessary for imprinted expression: when unmethylated it silences mRNA and activates non-coding RNA (ncRNA); it is inactive when methylated. An example is the 3.7 kb element within the *Igf2r* gene responsible for paternal-specific gene silencing of *Igf2r*, *Slc22a2*, and *Slc22a3* genes on mouse chromosome 17. **2** interleukin 1 β convertase.

iceberg a metaphor used to describe an interpretation of the anomalous entropies of solution of noble gases and other nonpolar substances in water, suggesting that water tends to organize itself into quasi-solid supramolecular structures around the molecules of such substances. In the case of alkyl compounds, this tendency increases markedly with the length of the alkyl chain.

Iceberg a human protein of the CARD family that binds caspase-1 tightly. It inhibits the generation of interleukin 1 β .

ICE-like protease any of a family of endopeptidases that structurally resemble **interleukin-1 β convertase** (ICE). They are involved in **apoptosis**, being implicated in the proteolysis that causes cell death.

I cell 1 *or* **CCK cell** any of a group of cells, widely distributed in the duodenal and jejunal mucosa, that produce **cholecystokinin**. So named because their histological features are intermediate between those of **S cells** and **L cells**. **2** *abbr. for* inclusion cell. *See also* **I-cell disease**.

I-cell disease *or* **inclusion-cell disease** *or* **mulcolipidosis II** an autosomal recessive disease in which most of the lysosomes in the connective tissue (fibroblasts) contain large inclusions of glycoaminoglycans and glycolipids as a result of the absence of several lysosomal hydrolases. These enzymes, which are synthesized in the endoplasmic reticulum, are secreted into the extracellular medium rather than being directed to the lysosomes. This is due to the absence of a mannose 6-phosphate marker on the carbohydrate moieties of these hydrolases because of a deficiency in an enzyme required for mannose phosphorylation. The failure of the phosphorylation in the *cis* Golgi network means that the enzymes are not segregated by the **mannose 6-phosphate receptors** into the appropriate transport vesicles in the *trans* Golgi network. The patients have an abnormally high level of lysosomal enzymes in their sera and body fluids. A milder form of I-cell disease is pseudo-Hurler polydystrophy.

ice point the temperature at which ice melts. It is taken as the temperature (273.15 K) at which ice and water are in equilibrium at standard pressure (101 325 Pa). It was used as a reference temperature on the Celsius scale, but the kelvin is based instead on the temperature at the **triple point** of water (273.16 K).

ICF *abbr. for* intracellular fluid.

ichthyosis a human condition in which the skin is thickened and scaly, as a result of a disorder of keratinization in the outer layers of the epidermis. An X chromosome-linked form is caused by mutations that produce deficiency of **steryl-sulfatase**. An autosomal dominant form results from mutations in the genes for keratin 1 or keratin 10. An autosomal recessive form is caused by deficiency of transglutaminase K. —**ichthyotic** *adj.*

ichthyotocin *an alternative name for* isotocin.

I-clip any intramembrane-cleaving protease, which may be a metalloprotease, serine protease, or aspartate protease.

icoso+ or (*before a vowel*) **icos+** *comb. form* recommended for denoting twenty or twenty times. Also (*formerly*): **eicoso+**, **eicos+**. (*Note*: the eicos(a)+ variant is still always used for the C₂₀ fatty acids and skeletally related compounds, e.g. the eicosanoids.)

icosadeltahedron (*pl.* **icosadeltahedra**) any solid geometrical figure obtained by dividing the triangular faces of an **icosahedron** into smaller triangles. If divided into more than four smaller triangles, the original faces will not be flat, in which case the 12 pentameric vertices will be supplemented by hexameric vertices. —**icosadeltahe-***dral* *adj.*

icosahedral symmetry a form of **cubic symmetry**, being the crystallographic symmetry displayed by an **icosahedron** and by the capsid of some types of virus.

icosahedron (*pl.* **icosahedra**) any solid geometrical figure having 20 triangular faces, 30 edges, and 12 pentameric vertices. A regular icosahedron has faces that are congruent plane equilateral triangles; there is twofold rotational symmetry about an axis through the midpoint of each edge, threefold rotational symmetry about an axis through the centre of each face, and fivefold rotational symmetry about an axis through each vertex. —**icosahedral** *adj.*

icosanoate or (*formerly*) **eicosanoate** *the systematic name for* arachidate.

icosanoid *the recommended name for* eicosanoid, but not generally used.

ICRO *abbr. for* International Cell Research Organization.

ICSH *abbr. for* interstitial cell-stimulating hormone (i.e. **luteinizing hormone**).

ICSU *abbr. for* International Council of Scientific Unions.

icterus (*in pathology*) *an alternative name for* jaundice.

icterogenic causing jaundice.

id or **i.d.** *abbr. for* **1** intradermal, or intradermally (alternative to ID). **2** inside diameter.

Id *abbr. for* inhibitor of differentiation; any of four mammalian helix-loop-helix (HLH) proteins (ID1 to ID4) that are negative regulators of cell differentiation. They form heterodimers, which do not bind to DNA, with certain ubiquitously expressed basic HLH proteins, and regulate tissue-specific gene expression.

ID *abbr. for* **1** (*in clinical chemistry*) iditol dehydrogenase (EC 1.1.1.14). **2** intradermal, or intradermally (alternative to id).

ID₅₀ or **ID50** *abbr. for* median infectious dose.

idoric acid the **aldaric acid** derived from idose.

IDDM *abbr. for* insulin-dependent diabetes mellitus (*see* **diabetes mellitus**).

+ide *suffix (in chemical nomenclature)* denoting a **lactide**. It replaces the terminal '+ic acid' of the trivial name of the parent hydroxy acid, and a multiplying prefix indicates the number of molecules of hydroxy acid involved; e.g. dilactide (formed from two molecules of lactic acid).

ideal describing any object, process, or system that is perfect, or that behaves exactly in accordance with some simple law or theory. *See also* **ideal gas**, **ideal solution**. —**ideality** *n.*

ideal gas any gas whose behaviour is accurately described by the **gas laws**.

ideal solution any solution in which, for each component,

$$d\mu_i = RT d\ln x_i,$$

where μ_i is the chemical potential of the *i*th component and x_i is its mole fraction, R is the universal gas constant, and T is the thermodynamic temperature. Integration of the above equation gives:

$$\mu_i = \mu_i^\circ + RT \ln x_i,$$

where μ_i° is the standard chemical potential of the *i*th component.

identity (*in sequence analysis*) the extent to which compared sequences have identical bases or residues at equivalent positions, usually expressed as a percentage.

identity matrix or **unitary matrix** *see* **scoring matrix**.

idio+ *comb. form* denoting **1** peculiar, distinct, one's own, separate. **2** self-produced, arising within.

idiogram or **karyogram** a diagrammatic representation of the **karyotype** of a cell, based on measurement of the chromosomes in several or in many cells.

idiom (*in immunology*) the group of **idiotypes** to which the **epitopes** carried by components of one individual animal belong.

idiopathic 1 (*in pathology*) describing a disease arising by itself, not consequent upon, or symptomatic of, another disease; of the nature of a primary morbid state; essential. **2** of the nature of a particular affection or susceptibility. —**idiopathy** *n.*

idiopathic autonomic neuropathy a severe subacute disorder caused by autoantibodies to ganglionic acetylcholine receptors (i.e. not those of neuromuscular junctions as in **myasthenia gravis**).

idiopathic pentosuria *see* **pentosuria** (def. 1).

idiotope 1 the group of **epitopes** carried by components of one individual animal. **2** as originally defined by Danish immunologist Niels Jerne (1911–94), an individual determinant (i.e. site) on an antibody molecule; together, the idiotopes constitute the idiotypic.

idiotypic 1 an antigenic specificity, particularly of antibodies directed against a single antigen. **2** any class or group of related antigenic characteristics or **idiotopes**; an **epitope** that is characteristic of a particular animal. —**idiotypic** *adj.*

iditol the hexitol derived formally by reduction of the aldehyde group of idose. L-Iditol is a rare natural product accompanying sorbitol in the fermented juice of berries of mountain ash (*Sorbus aucuparia*).

IDL *abbr. for* intermediate-density lipoprotein.

iDNA *abbr. for* intercalary DNA.

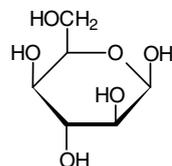

IDNPAP *abbr. for* isethionyl-3-(*N*-2,4-dinitrophenyl)amino propionimide; a reagent useful in the isolation of plasma membranes. It reacts with, but does not penetrate, the membranes and leaves the net charge on the proteins unaltered.

ido- *prefix (in chemical nomenclature)* indicating a particular configuration of a set of four (usually) contiguous >CHOH groups, as in the acyclic form of D- or L-idose. *See* **monosaccharide**.

Ido *symbol for* a residue (or sometimes a molecule) of the aldohexose idose.

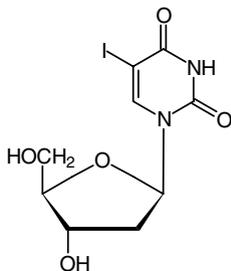

IdoA *symbol for* a residue of iduronic acid.

idose *symbol:* Ido; *ido*-hexose; an aldohexose whose D- and L-enantiomers are epimeric at C-2, C-3, and C-4 with D- and L-glucose, respectively.

β -D-idose

idoxuridine 5-iodo-2'-deoxyuridine; a pyrimidine nucleoside analogue, metabolized to the triphosphate, that inhibits DNA replication by substituting for thymidine in viral and mammalian DNA incorporation. It is used as an antiviral agent.

IDP *abbr.* for **1** the ribonucleotide inosine (5′)-diphosphate. **2** isopentenyl diphosphate (formerly called Δ³-isopentenyl pyrophosphate).

IDU *abbr.* for 5-iodo-2′-deoxyuridine (see **idoxuridine**).

IdUrd *symbol* for 5-iodo-2′-deoxyuridine (see **idoxuridine**) (preferred to IDU, IUdR, or IUdR).

iduronate **1** the anion of **iduronic acid**. **2** any salt or ester of iduronic acid.

iduronate-2-sulfatase EC 3.1.6.13; *other name*: chondroitin sulfatase; an enzyme that hydrolyses the 2-sulfate groups of the L-iduronate 2-sulfate units of dermatan sulfate, heparan sulfate, and heparin.

iduronic acid *symbol*: IdoA; the **uronic acid** formally derived from idose by oxidation to a carboxyl group of the hydroxymethylene group at position 6. In nature α-linked L-iduronic-acid residues, sulfated at position 2, occur in terminal positions in dermatan sulfate and heparan sulfate; these iduronic-acid residues are formed by epimerization of the configuration at C-5 of D-glucuronic-acid residues in these heteropolysaccharides.

L-iduronidase EC 3.2.1.76; an enzyme that hydrolyses α-L-iduronosidic linkages in desulfated dermatan. Deficiency leads to mucopolysaccharidosis I H.

iduronosyl the glycosyl group formed by removal of the anomeric hydroxyl group from **iduronic acid** or iduronate.

IE *abbr.* for **1** immunoelectrophoresis (alternative to IEP). **2** information extraction.

IEC *abbr.* for ion-exchange cellulose.

IED *abbr.* for individual effective dose. IED₅₀ denotes the median of the IEDs within a group of subjects.

IEF *abbr.* for isoelectric focusing.

IEP *abbr.* for immunoelectrophoresis (alternative to IE). **2** or *i.e.p.* isoelectric point (pI preferred).

IF *abbr.* for initiation factor. Suffixed numerals are added to designate individual factors, e.g. **IF-1**, **IF-2**, **IF-2a**, **IF-3**. Eukaryotic initiation factors are generally denoted by the prefix ‘e’, e.g. eIF-2, eIF-3.

IF-1 an *Escherichia coli* initiation factor.

IF-2 an *Escherichia coli* initiation factor.

IF-3 an *Escherichia coli* initiation factor.

IFCC *abbr.* for International Federation of Clinical Chemistry.

IFN *abbr.* for interferon. Suffixed Greek letters are added to differentiate the main classes, e.g. IFN-α, IFN-β, IFN-γ.

Ig *symbol* for immunoglobulin.

IgA *symbol* for immunoglobulin A.

IgA nephropathy a form of primary glomerulonephritis that is common throughout the world. There is reduced hepatic clearance of IgA, which deposits in the renal glomeruli.

IgA protease *another name for IgA-specific serine endopeptidase*.

IgA-specific serine endopeptidase EC 3.4.21.72; *other name*: IgA protease; a secreted bacterial serine protease that catalyses the cleavage of immunoglobulin A molecules at certain Pro-I-Xaa bonds in the hinge region. A signal peptide guides the enzyme precursor to the periplasmic space, and the C-terminal helper domain forms a pore in the outer membrane for exit of the protease domain. The helper domain is then released by autoproteolysis.

IG cell *abbr.* for intestinal gastrin cell; a small, granulated, gastrin-producing cell of the human upper small intestine. IG cells are smaller than, and ultrastructurally different from, CCK-producing **I cells**, gastrin-producing **G cells** of the gastric pylorus, and **TG cells**.

IgD *symbol* for immunoglobulin D.

IgE *symbol* for immunoglobulin E.

igensin a neutral cytosolic serine protease, activated by sodium dodecyl sulfate and found in a number of mammalian tissues.

IGF *abbr.* for insulin-like growth factor.

IGFBP *abbr.* for insulin-like growth factor binding protein.

IgG *symbol* for immunoglobulin G. Suffixed numerals are added to designate individual subclasses, e.g. IgG1, IgG2, IgG3, IgG4.

Ig-Heppta a rat glycoprotein (1389 amino acids) that is a G-protein-coupled membrane receptor with a long N-terminal extracellular region containing two C2-type Ig-homology units. It occurs on lung cell surfaces, and probably functions in cell adhesion and intracellular signalling. It defines a subgroup of G-protein-coupled receptors designated **LNB-TM7**.

Ig-like domain *see immunoglobulin fold*.

IgM *symbol* for immunoglobulin M.

β IG-M1 *see connective tissue growth factor*.

β IG-M2 *see connective tissue growth factor*.

ignose the name first proposed for ascorbic acid by A. Szent-Györgyi, before he knew its structure. *See also godnose*.

IGT *abbr.* for impaired glucose tolerance.

ii *see invariant chain*.

ii system a blood group system in which the antigenic determinant is an oligosaccharide related to the ABH system (*see ABH antigens*). Anti-I and anti-i are the major **cold autoantibodies**; the former occur in the transient anemia accompanying viral or *Mycoplasma pneumoniae* infections; the latter are characteristic of the chronic cold agglutinin disease, accompanying chronic lymphoproliferative diseases of the non-Hodgkin type. The structures of the determinants are: i determinant, GlcNAc(β1-3)Gal(β1-4)GlcNAcβ1-R; I determinant, Gal(β1-4)[Gal(β1-4)GlcNAc(β1-6)]GlcNAc(β1-3)-Gal(β1-4)GlcNAcβ1-R.

ikaros a protein that binds and activates the **enhancer** of a gene *CD3-δ* involved in T-lymphocyte specification and maturation. Similar to **hunchback**, it is a zinc-finger protein.

IL *abbr.* for interleukin. Various interleukins are distinguished by suffixed numerals, e.g. IL-1, IL-2, IL-3, etc.

ILA *abbr.* for insulin-like activity.

Ile *symbol* for a residue of the α-amino acid L-isoleucine (alternative to I).

ileum the lower part of the small intestine, extending from the jejunum to the large intestine. —**ileal** *adj.*

illegitimate transcription transcription at a low level of a normally tissue-specific transcribing gene in nonspecific cells.

Im *abbr.* for immunity protein.

IM or **i.m.** *abbr.* for intramuscular, or intramuscularly.

image analysis analysis of a digital image, characterizing its content in terms of, e.g., physical measurements, anomalous features, tagged pixels, or 2D or 3D representations suitable for computer graphics rendering.

imaging the production of an image of all or part of the body using techniques such as X-radiography, ultrasound scanning, nuclear magnetic resonance scanning, radionuclide scanning, or thermography and particularly used for gene expression and proteomic data. *Compare tomography*.

imidate **1** any salt or ester of an **imidic acid**. **2** to convert an oxo diacid into its corresponding **imide**. —**imidation** *n.*

imidazole or (formerly) **glyoxaline** or **iminazole** 1,3-diazole; 1,3-diaza-2,3-cyclopentadiene; a weak base, p*K*_a ~6.95, used as a **buffer** (def. 1). The numbering and tautomerism of the imidazole ring are described at **histidine**.

imidazole 4-acetate a product of histamine metabolism; it results from the action of monoamine oxidase on histamine to form imida-

zole 4-acetaldehyde, which is then oxidized by an NAD⁺-dependent aldehyde dehydrogenase to imidazole 4-acetate. *See also* **histidine**.

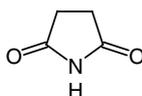

imidazoline receptor any mitochondrial or plasma membrane binding site for compounds from the generic groups imidazoles, imidazolines, imidazolidines, guanidines, and oxazolines, and having a putative endogenous ligand, **agmatine**. Imidazoline receptors occur throughout the brain, being possibly associated with glial cells, and in peripheral tissues. **I₁ receptors** have high affinity for *p*-aminoclonidine and are localized in plasma membranes. **I₂ receptors** have high affinity for idazoxan and are localized in mitochondrial membranes. The latter are known alternatively as nonadrenergic imidazoline binding sites (NAIBSS). Photoaffinity labelling to at least three proteins occurs: two, of 55 kDa and 61 kDa, respectively, are found in rat liver and differ in their affinity for the guanidium, amiloride; a third, of 61 kDa, is found in PC-12 cells and has high affinity for amiloride but low affinity for idazoxan. These proteins may represent different I₂ receptors. Subtypes of I₂ receptors are also suggested pharmacologically. The function of imidazoline receptors is not known, but many effects of imidazoline compounds, formerly attributed to their binding to α₂ receptors (e.g. hypotension), are now attributed to NAIBSS.

imidazolium 1 the cation formed by addition of a proton (hydron) to a molecule of **imidazole**. **2** the cationic chemical group formed by addition of a proton (hydron) to an **imidazolyl** group.

imidazolyl the chemical group derived formally by removal of one hydrogen atom from **imidazole**. The position from which the hydrogen atom has been removed may be indicated, e.g. 2-imidazolyl. The imidazolyl group is present in **histidine** and its derivatives.

imide any secondary organic amide (i.e., any diacyl derivative of ammonia or a primary amine), especially any that is a cyclic compound in which both of the acyl groups (which may be the same or different) are derived formally or actually from a diacid. (*Note*: non-cyclic symmetrical secondary organic amides are generically termed **diacylamines**.)

+imide *suffix* designating any organic compound that is an **imide**. The nitrogen atom may be substituted with a named alkyl or other group. An example is succinimide:

succinimide

imide acid any derivative of a carboxylic acid in which the carbonyl oxygen atom of the carboxyl group has been replaced by an **imino** (def. 1) or alkylimino group; i.e., any containing the =C(=NR)-OH group. *Distinguish from imino acid*.

imido+ *comb. form* designating any inorganic oxo acid (including the anions, salts, and esters) in which =O has been replaced by =NH or =NR (where R is a named substituent), or any derived di-, tri-, etc. acid in which a bridging oxygen atom, -O-, has similarly been replaced by -NH- or -NR-; e.g., **adenosine 5'-[β,γ]-imido]triphosphate**.

imidodipeptiduria or **prolidase deficiency** the presence in urine of peptides of structure X-Pro or X-Hyp in which X is frequently glycine. It results from deficiency of X-Pro dipeptidase and is accompanied by severe ulcers, mostly of the feet and hands, and frequently by mental retardation.

Imigran *see* **sumatriptan**.

iminazole a former name for **imidazole**.

imine 1 any organic compound containing one or more **imino** groups or substituted imino groups. **2** an obsolete term for azacycloalkene.

iminium the bivalent quaternary nitrogen-containing cationic group =⁺NR₂ attached to carbon in a chemical compound, where the R groups may each be hydrogen or any hydrocarbyl group.

imino the bivalent group =NH attached to carbon in a chemical compound.

imino+ *comb. form* denoting the presence in a chemical compound

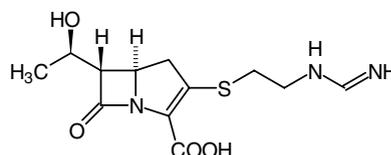

of one or more **imino** groups; the number of imino groups in the molecule may be specified, e.g. diimino+.

imino acid any carboxylic acid in which an imino substituent replaces two hydrogen atoms. In biochemistry, the term is commonly applied also to certain cyclic alkylamino (especially α-alkylamino) derivatives of aliphatic carboxylic acids, e.g. **proline**, although such compounds are now preferably classed as azacycloalkane carboxylic acids. *Compare imidic acid*.

iminodipeptidase *see* **Pro-X dipeptidase**.

imino glycinuria the secretion in urine of excessive amounts of glycine, proline, and hydroxyproline, due to a defect in their shared transport in renal tubules. The condition is clinically benign.

imipenem a carbapenem β-lactam antibiotic that is a semisynthetic derivative of thienamycin produced by *Streptomyces cattleya*. Its broad-spectrum antibiotic actions resemble those of penicillins, i.e. inhibition of bacterial peptidoglycan synthesis.

immediate gene or **immediate-early gene** *see* **early gene**.

immediate hypersensitivity or **type I hypersensitivity** a type of **hypersensitivity** responsible for asthma, hayfever, and some types of eczema. It occurs within minutes of exposure to antigen and depends on activation of **mast cells** and the release of mediators of acute inflammation. The mast cells bind **immunoglobulin E** (IgE) at their surface **Fc receptors** and when antigen cross-links the IgE, the mast cells degranulate releasing vasoactive amines that mediate the symptoms.

immobilize or **immobilise** to render any agent, whether a micro-macrosolute, a particle, or an intact cell, nondispersible in an aqueous medium with retention of its specific ligating, antigenic, catalytic, or other properties. Immobilization may be achieved by, e.g., encapsulation, entrapment in a small-pore gel, adsorption on, or covalent linkage to, an insoluble supporting material (matrix), or through formation of aggregates by cross-linkage.

immobilized enzyme *see* **solid-phase technique**.

immortalization or **immortalisation** the **transformation** of a cell population with a finite life span to one possessing an infinite life span. It is a characteristic of cancer cells, and is of practical importance in, e.g., the creation of **monoclonal antibodies**. Immortalization of eukaryotic cells may be effected experimentally by infection with certain viruses, or by fusion of the cell with a neoplastic cell to form a **hybridoma**. —**immortalize** or **immortalise** *vb*.

immotile cilia syndrome a genetically heterogeneous human disease characterized by impaired mobility or complete immobility of the cilia of airways and elsewhere and of sperm tails. Electron microscopy of such ciliated cells usually shows a lack of dynein arms between the longitudinal microtubular doublets, but other abnormalities may also be present.

immune 1 relating to or possessing **immunity**. **2** regarding or describing an animal that has been immunized. **3** an alternative word for **immunological**.

immune adherence the **complement**-dependent adherence of antibody-antigen complexes, or of antibody-coated bacteria (or other particles), to primate erythrocytes, causing the agglutination of the latter.

immune clearance an alternative term for **immune elimination**.

immune complex an alternative term for **antigen-antibody complex**.

immune complex-mediated hypersensitivity or **type III hypersensitivity** a type of **hypersensitivity** caused by the deposition of antigen-antibody complexes in tissue and blood vessels. The complexes activate **complement** and attract polymorphs and macrophages to the site.

immune cytotoxicity the **complement**-dependent lysis of cells by anti-

body molecules. When the cells concerned are erythrocytes the process is termed **immune hemolysis**.

immune elimination or **immune clearance** the accelerated, exponential removal of antigen from an immune animal as a result of complexing with antibody molecules.

immune globulin (*sometimes*) an alternative name for **immunoglobulin**.

immune hemolysis *see* **immune cytotoxicity**.

immune response the total immunological reaction of an animal to an immunogenic stimulus. It includes antibody formation, the development of hypersensitivity, and immunological tolerance.

immune serum an alternative term for **antiserum**.

immunity freedom and protection from 'infection'. Two forms of immunity can be recognized: (1) innate, meaning non-specific antimicrobial systems (e.g. phagocytosis) that are innate in that they are not intrinsically affected by prior contact with the infectious agent; and (2) the state of an animal that has an enhanced ability, above the nonimmune state, to respond to some (specific) antigen in which the antigen is bound and rendered inactive or eliminated from the body. *See also* **active immunity**, **passive immunity**.

immunity protein *abbr.*: Im; a protein, cosynthesized in *E. coli* with **colicin**, that binds to the nuclease domain of the colicin and inhibits its activity. Ims specific for RNase domains contain 84 amino acids, which form mostly beta strands. Those specific for DNase domains contain 86 amino acids and form four alpha helices.

immunization or **immunisation** any procedure carried out on an animal, e.g. the administration of antigen or antibody, that leads to an increased reactivity of the animal's immune system towards an antigen or antigens. —**immunize** or **immunise** *vb*.

immuno+ *comb. form* indicating immune or immunity.

immunoabsorbent any insoluble preparation of an antigen (or antibody) suitable for use in **immunoabsorption**. *See also* **immunosorbent**.

immunoabsorption the use of an insoluble antigen (or antibody) to remove specifically unwanted antibodies (or antigens) from a mixture so as to make the antibody (or antigen) more specific. *Compare* **adsorption** (def. 2). *See also* **immunosorption**.

immunoaffinity chromatography a type of **affinity chromatography** in which one of the two components of an antigen-antibody system is coupled to an insoluble matrix and used for the separation and purification of the other component.

immunoaffinity column a chromatographic column used in **immunoaffinity chromatography**.

immunoassay **1** any technique for the measurement of specific biochemical substances, commonly at low concentrations and in complex mixtures such as biological fluids, that depends upon the specificity and high affinity shown by suitably prepared and selected antibodies for their complementary antigens. A substance to be measured must be antigenic – either an immunogenic macromolecule or a haptenic small molecule. To each sample a known, limited amount of specific antibody is added and the fraction of the antigen combining with it, often expressed as the bound:free ratio, is estimated, using as indicator a form of the antigen labelled with a radioisotope (**radioimmunoassay**), fluorescent molecule (**fluoroimmunoassay**), stable free radical (**spin immunoassay**), enzyme (**enzyme immunoassay**), or other readily distinguishable label. The amount of the antigen in the sample is found by comparison with standards containing known amounts. *See also* **heterogeneous immunoassay**, **homogeneous immunoassay**, **saturation analysis**. **2** an alternative name for **radioimmunoassay**. **3** to carry out or to estimate (something) by an **immunoassay** (def. 1, 2).

immunobiology the branch of biology dealing with the activities of the cells of the immune system and their relationship to each other and to their environment. —**immunobiological** *adj*.

immunoblotting a technique for the detection of specific polypeptides separated by **polyacrylamide gel electrophoresis** (PAGE). The bands are transferred from the gel to a nylon or nitrocellulose membrane by Western blotting, followed by immunological detection of the immobilized antigen.

immunochemical **1** of or relating to **immunochemistry**. **2** any specific immunological reagent that consists of or incorporates an antigen or an antibody, especially one of commerce.

immunochemistry the branch of biochemistry dealing with the chemical nature of antigens, antibodies, and their interactions, and with the chemical methods and concepts as applied to immunology.

immunochromatogram the pattern of precipitation bands formed in **immunochromatography**.

immunochromatography any of various techniques for separating and identifying soluble antigens. In one method, analogous to **immuno-electrophoresis**, the antigens are first fractionated through a thin-layer chromatogram, e.g. of Sephadex; the fractions are then diffused against a trough containing a solution of antibodies (antiserum). In another method a small drop of antigen-antiserum mixture is applied to filter paper, or resin-impregnated paper, and the chromatogram developed with buffer; any antigen-antibody complex remains at the point of application and can be detected with a protein stain, while the other proteins are washed away from the origin.

immunocompetent cell an immunologically competent cell.

immunocyte any **immunologically competent cell**.

immunocytochemistry **cytochemistry** using appropriately labelled antibody preparations to detect specific cellular components. —**immunocytochemical** *adj*.

immunodeficiency any condition in which there is a deficiency in the production of humoral and/or cell-mediated immunity. —**immunodeficient** *adj*.

immunodeterminant an alternative name for **antigenic determinant**.

immunodiagnosis the diagnosis of disease by immunological methods.

immunodiagnostic **1** of or relating to **immunodiagnosis**. **2** any specific immunological reagent used in diagnosis.

immunodiffusion any of various analytical methods by which components of soluble antigen or antibody mixtures may be distinguished. Essentially, the antigens and antibodies are allowed to diffuse towards each other in a translucent gel, wherein they react to give lines or bands of precipitation in characteristic positions. Such methods include: **double immunodiffusion**, **electroimmunodiffusion**, **immunochromatography**, **immuno-electrophoresis**, **immunorheophoresis**, and **single radial immunodiffusion**. —**immunodiffuse** *vb*.

immunodominance the attribute of a part of an **epitope** that contributes a disproportionately great portion of the binding energy; e.g. the immunodominance shown by a monosaccharide residue in determining the antigenic specificity of a polysaccharide. —**immunodominant** *adj*.

immuno-electrofocusing or **immunoisoelectric focusing** a technique that is analogous to **immuno-electrophoresis** but with the preliminary fractionation of one of the reactants being effected by electrofocusing instead of electrophoresis.

immuno-electron microscopy a form of electron microscopy in which structures are stained with specific antibodies labelled with an electron-dense material.

immuno-electropherogram (*sometimes*) the record of an immuno-electrophoresis experiment, either the electrophoretic support itself or a tracing derived therefrom.

immuno-electrophoresis *abbr.*: IE or IEP; a technique for separating and identifying soluble antigens. It consists of **zone electrophoresis**, in a reasonably transparent gel, in one direction followed by **immunodiffusion** against a solution of antibodies (antiserum) placed in a trough parallel to the direction of electrophoresis. In suitable conditions each antigen shows up as an arc of precipitation in a characteristic position. —**immuno-electrophoretic**, **immuno-electrophoretical** *adj*.

immunoenzymatic of or pertaining to the particular techniques used in **immunoenzymology**.

immunoenzymology the subspeciality of immunochemistry in which the activity of enzymes coupled to antigens or antibodies is utilized as a molecular amplifier of antigen-antibody reactions.

immunofixation or **immunofixation electrophoresis** a variant of **immuno-electrophoresis**, or **immuno-electrofocusing**, in which proteins of a single immunological species are anchored to the support by treatment with monospecific antibodies, allowing the other proteins to be washed out of the support. It is useful in the identification of proteins in complex mixtures or of minor proteins obscured in electrophoretic patterns.

immunofluorescence or **immunofluorescence microscopy** a technique in which an antigen or antibody is made fluorescent by conjugation to a fluorescent dye and then allowed to react with the complementary antibody or antigen in a tissue section or smear. The location of the antigen or antibody can then be determined by observing the fluorescence by microscopy under ultraviolet light. —**immunofluorescent** *adj.*

immunogelfiltration a variant of **radial single immunodiffusion** in which antigen is first fractionated according to its molecular size by permeation, in a buffer solution, into a thin layer of an appropriate cross-linked dextran gel. The dextran layer is then covered with a layer of agarose gel containing antibody. Rings or spots of antigen-antibody precipitate develop in the agarose gel over the complementary antigens.

immunogen 1 any substance that, when introduced into the body, elicits humoral or cell-mediated immunity, but not immunological tolerance. **2** any substance that is able to stimulate an immune response, as distinct from substances (antigens) that can combine with antibody. **3** any substance that is able to stimulate protective immunity against a pathogen, as distinct from an immune response that is of no intrinsic value to the animal immunized. —**immunogenic** *adj.*

immunogenetics (*functioning as sing.*) the branch of biology that combines immunology and genetics. It includes the use of immunological methods and knowledge in the study of genetics, and the use of genetics in the study of immunological phenomena and substances. —**immunogenetic** *adj.*

immunogenicity *an alternative term for antigenicity.*

immunoglobulin *symbol:* Ig; any protein occurring in higher animals as a major component of the immune system. Immunoglobulins are produced by lymphocytes, and virtually all possess specific antibody activity. Each immunoglobulin comprises four polypeptide chains, two identical **heavy chains** and two identical **light chains**, linked together by disulfide bonds; all contain in addition differing amounts of attached oligosaccharide. There are five classes, IgA, IgD, IgE, IgG, and IgM. The primary structures of the heavy chains differ among the various classes, being designated α , δ , ϵ , γ , and μ , respectively, and there are two types of light chain, κ and λ . IgA and IgM molecules contain multiples of the four-chain unit. The homology units form a characteristic structure, the **immunoglobulin fold**. *See also immunoglobulin A, immunoglobulin D, immunoglobulin E, immunoglobulin G, immunoglobulin M.*

immunoglobulin A *symbol:* IgA; an immunoglobulin found in human plasma, mostly as a 170 kDa monomer of the basic four-chain immunoglobulin structure or, as a 400 kDa dimer, together with an extra 15 kDa polypeptide, the **J chain**, linked to **secretory piece**. It is the major immunoglobulin of seromucous secretions, in which it protects external body surfaces against attack by microorganisms. It has the structure $(\alpha_2)_n J$, where α is the heavy chain, I is the light chain (κ or λ), J is the J chain, and n is 1 or 2. *See also IgA-specific serine endopeptidase.*

immunoglobulin amyloidosis the commonest form of systemic amyloidosis in humans. The amyloid fibrils consist of λ and κ Ig light chains that are overproduced by a clone of B lymphocytes.

immunoglobulin D *symbol:* IgD; a 185 kDa immunoglobulin that is very susceptible to proteolytic degradation and has a very short half-life in plasma. It is found in an integral membrane protein form, together with immunoglobulin M, on the surface of B lymphocytes, where both function as antigen receptors and control lymphocyte activation and suppression. It has the structure $\delta_2 J_2$ where δ is the heavy chain and I is a light chain (κ or λ). *See hyper-IgD syndrome.*

immunoglobulin E *symbol:* IgE; a 200 kDa immunoglobulin of high carbohydrate content, normally found in very low concentrations in plasma, although its concentration there is elevated in allergic conditions. IgE is synthesized mainly in lymphoid tissue of gut and respiratory tract. It binds strongly to mast cells and contact with antigen leads to degranulation of the mast cells and release of inflammatory mediators. It has the structure $\epsilon_3 J_2$ where ϵ is a heavy chain and I is a light chain (κ or λ).

immunoglobulin fold a series of β strands, arranged as two antiparallel β sheets packed tightly against each other, that is highly

characteristic of immunoglobulin homology units. In the constant region, the two β sheets consist of four and three β strands respectively. In the variable region there are nine β strands (five and four). This type of structure is found in many other proteins, especially cell surface receptors, and is often referred to as an **Ig-like domain**.

immunoglobulin G *symbol:* IgG; the principal immunoglobulin of human plasma and other internal body fluids. It is a 150 kDa protein and is the major immunoglobulin synthesized during the secondary response to an antigen. In the tissue fluids it neutralizes bacterial toxins and binds to microorganisms thereby enhancing their phagocytosis. Complexes of IgG with microorganisms activate **complement** by the classical pathway. IgG binds to macrophages and polymorphonuclear leukocytes and can cross the placenta. It has the structure $\gamma_2 J_2$ where γ is a heavy chain and I is a light chain (κ or λ). There are subclasses of IgG depending on different types of γ chain.

immunoglobulin M *symbol:* IgM; a 900 kDa immunoglobulin consisting of a star-shaped polymer of five basic four-chain structures, each heavy chain bearing an extra constant domain. Polymerization is dependent on the presence of **J chain**, which may act to stabilize the sulfhydryl groups in the constant portion of the heavy chains during IgM synthesis. IgM is produced early in the immune response and is mainly found intravascularly. Because of its high antigen-combining valency it is very effective in binding microorganisms and mediating **complement**-dependent cytotoxicity. It has the structure $(\mu_5)_2 J$ where μ is a heavy chain, I is a light chain (κ or λ), and J is a J chain. Virgin B lymphocytes have a transmembrane sequence at the C terminus of μ and the switch is effected by alternative splicing. In **heavy chain disease** the protein has no C and C_{H1} regions due to deletion. *See hyper-IgM syndrome.*

immunoglobulin superfamily a superfamily of proteins that have similarities of sequence and structure to immunoglobulins. There are three sets, based on immunoglobulin domains: one with variable-like domains, the V set, and two with variants of the constant-like domains, the C1 and C2 sets.

immunogold labelling a method of labelling specific molecules in electron-microscopic thin sections using electron-dense gold particles attached to specific antibody molecules.

immunogram (*sometimes*) the pattern of bands or lines of precipitation formed in a gel by **immunodiffusion**.

immunohistochemistry a form of **histochemistry** in which appropriately labelled antibody preparations are used to detect specific structures in tissues. —**immunohistochemical** *adj.*

immunoliposome a **liposome** bearing a chemically coupled monoclonal antibody.

immunolocalization or **immunolocalisation** the use of appropriately labelled antibody (or antigen) preparations to detect the position of specific structures or components that contain or are the complementary antigens (or antibodies).

immunological or (*esp. US*) **immunologic** of, concerned with, or pertaining to immunity or immunology. —**immunologically** *adv.*

immunologically competent (of cells, tissues, etc.) qualified for and capable of giving an **immune response**.

immunological paralysis *an alternative name for acquired tolerance.*

immunological rejection the destruction, by a specific immune reaction, of foreign cells or tissues transplanted or inoculated into a recipient animal from a donor animal.

immunological response any specific response to an antigen. It includes **cell-mediated immunity**, **humoral immunity**, and **immunological tolerance**.

immunological surveillance the postulated monitoring of the cells of large, long-lived animals by their immunological systems so that aberrant cells arising from somatic mutations, and so containing new antigens, are destroyed.

immunological tolerance a type of immunological response in which there develops a specific nonreactivity of the lymphoid tissues towards a given antigen, one that in other circumstances is able to induce cell-mediated or humoral immunity. Immunological tolerance may follow contact with the antigen in fetal or early postnatal life or the administration of the antigen to adults (**acquired tolerance**). The reaction towards other, unrelated antigens is unaffected.

immunology the study of **immunity** and related phenomena. The science of immunology grew out of the study of resistance to infectious disease, and now encompasses the study of antigens, antibodies, and their interactions both *in vivo* and *in vitro*, and the cellular phenomena of recognition of, and responsiveness to, foreign substances. Related disciplines include **immunobiology** and **immunochemistry**.

immunometry the measurement of amounts of substances by the use of specific antigen–antibody reactions. —**immunometric** *adj.*; **immunometrically** *adv.*

immunomodulation the alteration of an immune response by an agent other than the antigen.

immunomodulator any agent that alters the extent of the immune response to an antigen, by altering the antigenicity of the antigen or by altering in a nonspecific manner the specific reactivity or the nonspecific effector mechanisms of the host. Immunomodulators include adjuvants, immunostimulants, and immunosuppressants.

immunoosmophoresis *an alternative term for counter(immuno)electrophoresis.*

immunophenotyping the **typing** of cells with immunological markers such as monoclonal antibodies.

immunophilin one of a conserved group of proteins that bind the immunosuppressant drugs cyclosporin A, FK506, and rapamycin. All have peptidylprolyl isomerase activity and play major roles in protein folding and trafficking within cells. Cyclosporin A binds to a cyclophilin, while FK506 and rapamycin bind to FK506-binding proteins (FKBPs). Immunophilins inhibit S6 kinase and several cyclin-dependent kinases. They also bind to the Hsp90 component of unliganded steroid hormone receptors. *See mTor.*

immunoprecipitate **1** the precipitate formed in an antigen–antibody reaction. **2** to precipitate (something) by reaction with a specific antibody or antigen. —**immunoprecipitation** *n.*

immunoradiometric assay *abbr.*: IRMA; an alternative method to **radioimmunoassay** for the measurement of very small amounts of nonradioactive material. An excess amount of a specific antibody labelled with a radioactive isotope is added to the sample containing the substance to be assayed. After equilibration, unreacted antibody is removed and the amount of radioactive material remaining is measured.

immunoreactive capable of reacting with a specific antibody. The term is used especially of substances that react with an antibody directed against a particular peptide hormone (or part of such a hormone) but that do not necessarily exhibit the expected physiological or pharmacological activity. —**immunoreactivity** *n.*

immunosorbent any sorbent used in, or useful for, **immunosorption**. *See also immunoabsorbent.*

immunosorption the use of antigens (or antibodies) immobilized on a solid matrix to remove specifically the complementary antibodies (or antigens) from a mixture and their subsequent elution from the solid phase. It is used in, and is useful for, purification of antibodies (or antigens). *See also immunoabsorption.*

immunostimulant any agent that nonspecifically enhances the immunologically specific reactivity of an animal to an antigen and also the animal's nonspecific effector mechanisms. —**immunostimulatory** *adj.*

immunosuppressant or (*sometimes*) **immunosuppressive** any agent that causes **immunosuppression**.

immunosuppressed describing an organism that is incapable of showing an immune response to an antigen.

immunosuppression the suppression of immune responses to antigens. This can be achieved by various means, including physical (e.g. X-irradiation), chemical (e.g. antimetabolic drugs), or biological (e.g. antilymphocyte serum). After transplant surgery **azathioprine** is commonly used. This drug has a preferential effect on T-cell-mediated reactions. It is degraded in the body first to mercaptopurine and is then converted to the active agent, the ribotide, which inhibits nucleic-acid synthesis. **Methotrexate**, cyclophosphamide, **cyclosporin A**, and **FK506** are also highly effective immunosuppressants, the latter two being used extensively. Infection by HIV-1 eventually leads to a reduction in the population of helper T-cells and macrophages. This immunosuppression of the system is associated with occurrence of **Kaposi's sarcoma** and allows

infection by agents such as *Pneumocystis carini*, cytomegalovirus, and tuberculosis. *Compare immunodeficiency. See also suppressor cell.*

immunosuppressive **1** able to cause **immunosuppression**. **2** *an alternative term for immunosuppressant.*

immunosympathectomy the destruction of some or all of the neurons of the sympathetic nervous system by injections into a newborn animal of an antiserum to the appropriate **nerve growth factor**.

immunotoxin any of a class of therapeutic drugs consisting of a monoclonal antibody linked to a toxic protein (e.g. ricin, diphtheria toxin).

IMP *abbr. for 1* inosine monophosphate; i.e. inosine phosphate. **2** ion-moderated partition.

impaired glucose tolerance *abbr.*: IGT; the term recommended to denote a clinical state or condition of humans that is intermediate between the normal one and the overtly diabetic. Characteristically, in a standard oral **glucose-tolerance test** in non-pregnant adults, the glucose concentration in capillary whole blood or venous plasma taken at 2 hours is in the range 8–11 mmol L⁻¹ (1.4–2.0 g L⁻¹); the corresponding values for venous whole blood are 7–10 mmol L⁻¹ (1.2–1.8 g L⁻¹). In addition, the fasting plasma glucose must be below 8 mmol L⁻¹, and plasma glucose during the test must be greater than 11 mmol L⁻¹ at 30, 60, and 90 min.

IMP cyclohydrolase EC 3.5.4.10; *other names*: IMP synthetase; inosinicase; an enzyme of the pathway for *de novo* purine biosynthesis that cyclizes 5-formamido-1-(5'-phosphoribosyl)imidazole-4-carboxamide to IMP with elimination of H₂O. For an example, *see phosphoribosylaminoimidazolecarboxamide formyltransferase.*

IMP dehydrogenase EC 1.1.1.205; *other name*: inosine-5'-monophosphate dehydrogenase; an enzyme that catalyses the conversion of inosine 5'-phosphate, NAD⁺, and H₂O to xanthosine 5'-phosphate and NADH. The reaction involves the introduction of an oxo group at the purine C-2. Xanthosine 5'-phosphate is then converted to guanosine 5'-phosphate by **GMP synthase** (glutamine hydrolysing). In humans there are two isoenzymes.

impedance *symbol*: Z; the quality determining the amplitude of the current flowing in a circuit for a given applied alternating electric potential. It depends upon the electric resistance, self-inductance, and capacitance of the circuit.

impeller **1** the vaned, rotating disk of a centrifugal pump. **2** any device incorporating an **impeller** (def. 1).

impermeable (of a substance or structure) not permitting the passage through it of a fluid or of a particular solute in a fluid; not permeable. —**impermeability** *n.*

impermeant (of a fluid or a solute in a fluid) incapable of passing through a particular substance or structure.

importin or **karyopherin** a heterodimeric protein essential for the import of proteins from the cytoplasm to the nucleus. The α subunit binds the nuclear localization signal of the cargo protein, and the β subunit binds to nucleoporins of the nuclear pore. Entry into the nucleus is mediated by the GTPase Ran, and the α and β subunits subsequently exit the nucleus separately. Importin is also involved in aster formation during cell division.

imprinting (*in genetics*) the phenomenon whereby the expression of genes is determined by the parent who contributed them. For example, the onset of Huntington's disease is earlier if the defective allele is inherited from the father rather than the mother. A maternal allele can be expressed exclusively because the paternal allele is silenced by methylation or other modification, or vice versa. Some 70 imprinted genes have so far been discovered in both mouse and human, and of these roughly half are maternally imprinted and half paternally.

impulse **1** (*in physics*) a vector quantity equal to the integral of the force, F , acting on a body with respect to the time, t , over which the force acts: $\int F dt$. If the force is constant the expression reduces to the product Ft . It also equals the total change of momentum of the body induced by the applied force. **2** (*in physics*) an electrical surge of unidirectional polarity. **3** (*in physiology*) or **nerve impulse** an all-or-none signal propagated along the axons of neurons by which information is transmitted rapidly and precisely through the nervous system. It consists of a sequence of changes in ionic permeability of the neuronal membrane that gives rise to ionic currents and associated changes in transmembrane electrical potential.

impure not pure, lacking purity; (of a substance or material) containing contaminants.

impurity **1** the state or quality of being impure. **2** any or all of the admixed components in an impure substance or material.

impurity quenching chemical quenching due to an **impurity** (def. 2). **In** symbol for indium.

inappropriate secretion a clinical syndrome in which the secretion of a specified hormone, commonly **antidiuretic hormone**, is abnormally high relative to the state of the normal regulatory mechanisms. It is so termed because it results from an unknown or unmistakably abnormal cause and serves no recognizable homeostatic function.

inborn error of metabolism any genetically determined biochemical variation occurring in humans. Such variations are highly specific and represent many diverse metabolic phenomena, resulting in very varied effects on the viability of the individual. The first such errors were publicized in 1909 by the British physician Archibald Garrod (1857–1936) in his book *Inborn Errors of Metabolism*.

inbred strain or **inbred line** a group of organisms obtained by repeated inbreeding over several successive generations, e.g. by self-pollination in plants or by repeated brother × sister matings in animals. Eventually, all individuals will possess identical sets of **autosomes**, and all the chromosome pairs will become homozygous.

INCHI *abbr.* for International chemical identifier.

inclusion (*in cytology*) **1** any discrete body or particle within a cell, especially a passive product of cell activity such as a starch or volutin granule. **2** an alternative (*less common*) name for **inclusion body**.

inclusion body or **inclusion** **1** any discrete assembly of virions and/or viral particles that may be visualized in virus-infected cells, either in the nucleus or in the cytoplasm. **2** (*in bacteriology*) any one of a number of bodies found within bacterial cells, such as storage granules (e.g. of glycogen, poly- β -hydroxybutyrate, polyphosphate, or sulphur), gas vacuoles, carboxysomes, and magnetosomes. **b** an insoluble complex of protein stored within the cytoplasm of bacterial cells and resulting from the overexpression of a foreign protein.

inclusion cell *abbr.*: I cell; a type of cell that is seen in tissues from patients with mucopolipidosis II (**I-cell disease**) and that contains inclusions consisting of very large lysosomes whose contents are heterogeneous, comprising mucopolysaccharide, whorls of membrane, and other material.

inclusion-cell disease or **mucopolipidosis II** *see* **I-cell disease**.

inclusion complex or **inclusion compound** any chemical complex in which one component (the host molecule) forms a crystal lattice containing tunnel- or channel-shaped spaces in which molecular entities of a second species (the guest molecule) are located. There is no bonding between the host and the guest molecules.

incompatibility **1** a criterion for classifying bacterial **plasmids**; two plasmids of the same incompatibility group cannot coexist in one host cell. The molecular basis is that the incompatible plasmids share sites during plasmid **segregation** (def. 3). **2** (*in phylogeny*) an alternative name for **incongruence**. **3** the state of being **incompatible**.

incompatibility group a group to which plasmids are said to belong if they cannot coexist in the same bacterial host over several generations without selection.

incompatible **1** (*in immunology*) having antigenic nonidentity between a donor and a recipient, e.g. in blood transfusion or tissue transplantation. **2** (*in therapeutics*) (of two drugs) incapable of being used together or combined; antagonistic.

incomplete antibody **1** any antibody whose activity in an agglutination test can only be demonstrated indirectly, e.g. by an antiglobulin test. **2** (*sometimes*) a univalent antibody fragment produced enzymically, e.g. a **Fab fragment**.

incomplete Freund's adjuvant *see* **Freund's adjuvant**.

incongruence or **incompatibility** (*in phylogeny*) difference of characters or trees suggesting different groups of relationships, owing to the presence of **homoplasy**.

incorporation **1** the act or process of including (something) as a part of a whole. **2** (*in biochemistry*) the inclusion of (isotopically labelled) metabolites, by covalent linkage, into biopolymers by living cells or cell-free preparations; often taken as an index of biosynthesis. —**incorporate** *vb*.

incretin a putative insulinogenic principle secreted from the duodenum and jejunum in response to the presence of glucose. Its effects are now generally considered to be attributable to **glucose-dependent insulinotropic peptide**.

incubate **1** to maintain at an appropriate temperature so as to favour growth, development, or continued survival (e.g. of cells); by extension, to maintain under specified conditions in a controlled or artificial environment (e.g. in studies of enzymic or antigen–antibody reactions), especially at a particular ambient temperature (which may be above or below that of the environment). **2** a material or preparation that has been incubated. —**incubation** *n*.

incubation mixture any reaction mixture that is maintained at a controlled temperature and/or in a controlled, artificial environment.

incubation period **1** (*in pathology*) the time interval between the invasion of an organism by a pathogenic virus or microorganism and the overt manifestation of disease. **2** (*in microbiology*) the period of development of a culture of bacteria or other microorganisms.

incubator any closable, heat-insulated cabinet that is maintained at a constant internal temperature (and, sometimes, humidity and/or atmosphere) and that is used for the growth or maintenance of cells, cultures, tissues, or organisms, or for the hatching of eggs.

indel an inserted or deleted position within a DNA or protein sequence **alignment**. The term reflects the difficulty in knowing whether the base or residue represents an insertion in one sequence or a deletion in the other relative to an ancestral sequence.

Inderal *see* **propranolol**.

index (*pl. indices or indexes*) (*in informatics*) a table of relations (or addresses) between or within data sets that enables rapid file searching. Searches are directed only to specific data subsets, obviating the need to search the data set serially. For example, SRS (Sequence Retrieval System) operates by searching indexed flat-file databases. *See* **information retrieval software**.

index of refraction *see* **refractive index**.

Indian tobacco *see* **lobelia**.

indican **1** **metabolic indican** indol-3-yl hydrogensulfate; 3-indoxyl-sulfuric acid; a so-called ethereal sulfate, formed in the gut by bacterial action on tryptophan and excreted in the urine, where its level may be taken as an index of intestinal stagnation. **2** **plant indican** indol-3-yl- β -D-glucopyranoside; indoxyl- β -D-glucoside; a substance isolated from *Indigofera* spp., members of the Leguminosae, and *Polygonum tinctorium*. The glucoside is hydrolysed during extraction by water or dilute acid, and the indoxyl is liberated spontaneously, oxidizing to the blue dye indigo.

indicated hydrogen *symbol*: *H-* (*or sometimes H*) (with a prefixed locant); (*in chemical nomenclature*) an atom of hydrogen whose position in the molecular structure of an unsaturated cyclic organic compound or group requires to be explicitly stated in order to make the name of the compound or group specific to a particular structural isomer (or tautomer) if otherwise the name would apply equally to two or more isomers (or tautomers). The compound or group in question commonly consists of or is derived from a condensed ring system with the maximum number of non-cumulative double bonds, although the notation is applied also to certain monocyclic systems. The symbol (with its locant) ordinarily precedes the name or the relevant part of the name, e.g. 1*H*-purin-6-amine or 6-amino-1*H*-purine (alternative semisystematic names for one of the tautomers of adenine); however, where the insertion of a substituent into a cyclic structure has necessitated the addition of a hydrogen atom at another position the symbol is placed in parentheses after the locant for the substituent, e.g. purin-6(1*H*)-one (*a semisystematic name* for one of the tautomers of hypoxanthine).

indicator **1** any substance used in a chemical operation to indicate by a colour change the completion of a reaction or the attainment of a desired state. **2** any substance that by a characteristic colour change indicates the presence of another particular substance. **3** (*in saturation analysis*) the labelled substance whose distribution between the reactants of the system is used to determine the amount of analyte present. **4** an isotope, often a radioactive one, that is used as a tracer.

indicator enzyme an alternative name for **marker enzyme**.

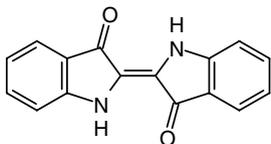

indicator organism or **indicator species** any species of organism

whose presence or population characteristics in a particular habitat are used to provide information about the nature of that habitat, especially regarding its degree of pollution.

indicator yellow the original name for *N*-retinylidene opsin. It was so called because its colour changes between yellow and orange according to the pH of its aqueous solution. It spontaneously hydrolyses into opsin and (all-*trans*)-retinal. See **rhodopsin**.

indigo a blue dye prepared from the same plants as plant **indican**. Its major blue component is **indigotin**.

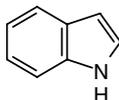

indigotin [*A*^{2,2'}-biindoline]-3,3'-dione; the major blue component of **indigo**.

indirect antagonism a form of **antagonism** (def. 2) arising as a consequence of competition by the antagonist for the binding site of an intermediate that links receptor activation to the observed effect.

INDO-1 1-[2-amino-5-(6-carboxyindol-2-yl)phenoxy]-2-(2-amino-5-methylphenoxy)ethane-*N,N,N',N'*-tetraacetic acid; a fluorescent calcium chelator, named from the indolyl moiety, that can be used as an indicator of Ca^{2+} concentration; it has a large shift in fluorescence emission, from 480 to 400 nm, on binding Ca^{2+} .

indole 2,3-benzopyrrole; in plants and microorganisms, a precursor in the biosynthesis of tryptophan. In animals it is formed by the degradation of tryptophan by bacteria in the intestinal tract.

indoleacetate *abbr.*: IAA; the anion of indole-3-acetic acid. Formed from *L*-tryptophan, it is a plant hormone, and the main **auxin** of higher plants.

indoleacetoneitrile *abbr.*: IAN; an **auxin**, second in abundance to indoleacetate.

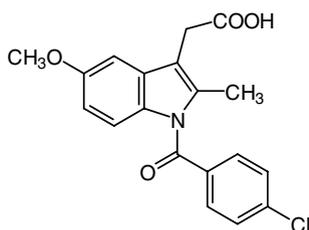

indole-3-glycerol-phosphate synthase see **trp genes**.

indole test a test used for the identification of certain microorganisms, e.g. members of the Enterobacteriaceae. It determines the ability of the organism to produce indole from tryptophan.

indolicidin a bactericidal and fungicidal 13-residue peptide amide from the cytoplasmic granules of bovine neutrophils. It contains five tryptophan residues, hence its name. Some therapeutic success has been achieved in animals against the fungus, *Aspergillus fumigatus*, using liposomally encapsulated indolicidin, indicating that neutrophil-derived antimicrobial peptides may have therapeutic value.

indoloria the presence in (human) urine of compounds containing an indole ring.

indomethacin 1-(*p*-chlorobenzoyl)-5-methoxy-2-methylindole-3-acetic acid; an inhibitor of **prostaglandin-endoperoxide synthase**. It is useful as an anti-inflammatory drug.

INDOR *abbr.* for internuclear double resonance spectrometry.

induced enzyme or **inducible enzyme** any enzyme that is synthesized in a cell only in very small amounts except when induced by the presence of its substrate or a closely related compound. Compare **constitutive enzyme**.

induced-fit theory an explanation, first proposed by D. E. Koshland, of enzyme specificity. It holds that reaction between an enzyme and its substrate occurs only following a change in the enzyme's structure, induced by the substrate. It proposes that: (1) a precise orientation of catalytic groups is required for enzyme action; (2) the substrate may cause a change in the three-dimensional relationship of the amino-acid residues at the active site; and (3) the changes in enzyme structure will bring the catalytic groups into the proper orientation for reaction, whereas a nonsubstrate will not. Compare **lock-and-key model**.

inducer (*in genetics*) a molecule, generally small, that acts by binding either to an activator or to a repressor protein to stimulate gene expression.

inducible capable of being induced.

inducible enzyme an alternative name for **induced enzyme**.

induction 1 see **Jacob-Monod model**. **2** (*in physics*) any physical effect brought about (i.e. induced) in an object by the action of a field without any direct physical contact with the inducer. It may be electrostatic, magnetic, or electromagnetic. See also **induced enzyme**. **3** (*in genetics*) the mechanism whereby a bacteriophage in the lysogenic state is prompted to enter the lytic mode of replication. Induction occurs under adverse nutritional conditions and classically by exposure of the lysogen to ultraviolet irradiation.

induction coil a device for producing a rapid succession of large pulses of induced emf in a secondary coil from an intermittent low emf in a primary coil.

induction motor an electric motor in which an alternating current is supplied to the winding of the stator, arranged in such a manner as to produce in effect a rotating magnetic field. This in turn induces electric currents in the winding of the rotor, and interaction between these currents and the magnetic flux exerts a torque on the rotor. Induction motors are useful in situations where sparks caused by moving electric contacts are undesirable.

inductive effect (*in chemistry*) *symbol*: *I*; an experimentally observable effect (on reaction rates, etc.) caused by the transmission of charge through a chain of atoms by electrostatic induction. It is symbolized by +*I* or -*I*, according to whether the group in question is left with a small positive or a small negative charge.

+ine suffix designating **1** an organic compound that is either an amine (including any monoamino monocarboxylic acid other than tryptophan), or a nitrogen-containing heterocycle other than one containing four or five atoms in the ring. **2** a halogen. **3** any of a group of certain inorganic binary hydrogen compounds, namely arsine, bismuthine, phosphine, and stibine; also hydrazine.

inert 1 having little or no ability to react chemically or physiologically. **2** having no inherent ability to move or resist being moved. —*inertness n.*

inertia 1 (*in physics*) the tendency of an object to resist changes to its state of rest or uniform motion; by analogy extended to other physical qualities that resist change. **2** the state of being inert or inactive. —*inertial adj.*

inertial mass see **mass**.

infantile Refsum disease see **Refsum disease**.

infantile sialic acid storage disease *abbr.*: ISSD; the fulminant form of **Salla disease** and, like it, caused by mutations in sialin.

infect 1 to cause infection in (an organism, wound, etc.), especially with pathogenic microorganisms. **2** to affect or become affected with a communicable disease.

infection 1 the invasion of a cell or organism by other (especially pathogenic) organisms. **2** the act or process of infecting; the state of being infected. **3** any agent or process that infects.

infectious 1 (*of a disease*) caused by pathogenic (micro)organisms. **2** causing or transmitting infection. **3** (*of a disease*) capable of being transmitted to another organism. —*infectiously adv.*; *infectiousness n.*

infectious mononucleosis see **Epstein-Barr virus**.

infectious viral nucleic acid a purified viral nucleic acid that,

when it infects a host cell, causes the production of progeny viral particles.

infective 1 capable of causing infection. **2** *an alternative (less common) word for infectious.* —**infectively** *adv.*; **infectiveness** or **infectivity** *n.*

infinite having no limits in extent, magnitude, space, or time; immeasurably numerous or great. —**infiniteness** *n.*; **infinitely** *adv.*

infinite dilution a hypothetical state (of a solution) in which the solute concentration is considered to be zero and the activity coefficient unity.

infinitely thick (*of a radioactive sample*) having a thickness no less than **infinite thickness** for the particular radionuclide to be measured.

infinitely thin (*of a radioactive sample*) having a thickness no greater than **infinite thinness** for the particular radionuclide to be measured.

infinite thickness the thickness of a sample containing a particular radionuclide, especially a soft beta-emitter, beyond which, because of self-absorption, any increase results in no further increase in recordable disintegrations. Under these conditions the (radio)activity is proportional to the specific (radio)activity of the substance.

infinite thinness the thickness of a sample containing a particular radionuclide at or below which self-absorption is negligible. Under these conditions the (radio)activity is proportional to the amount of the radionuclide present.

inflammable very liable to catch fire and produce flame; flammable.

inflammation the immediate defensive reaction of vertebrate tissue to infection or to injury by chemical or physical agents. The part affected is characterized by pain, heat, redness, swelling, and loss of function; there is local vasodilatation, extravasation of plasma into the intercellular spaces, and accumulation of white blood cells and other macrophages in the injured part. Plasma enzyme systems are important sources of inflammatory mediators. These include the **complement**, **blood coagulation**, fibrinolytic, and **kinin** systems. Also active are the mediators released by mast cells, basophils, and platelets, as well as the eicosanoids generated by many cells at inflammatory sites. —**inflamm** *vb.*

influenza virus any one of several orthomyxoviruses that cause respiratory disease in warm-blooded vertebrates. Influenza viruses are negative strand RNA viruses with segmented genomes comprising eight RNA molecules per virion. Influenza viruses are characterized by their antigenic properties. The matrix serotypes are referred to as A, B, and C. Influenza B and C types are only found in the human species whereas type A viruses infect several species and some can cross a species barrier. They are conventionally sub-typed according to their haemagglutinin (H) and neuraminidase (N) antigens. A complete designation is, for example, A.Hong Kong/1/68 (H3N2) meaning it is a type A, isolated in Hong Kong, was the first such virus isolated there in 1968, and is H3N2.

informatics 1 the science concerned with the structure and properties of scientific information, its theory, history, methodology, and organization. **2** the application of computational and statistical techniques to the management and analysis of information. For example, bioinformatics relates to the management and analysis of biological information; medical informatics to medical information; neuroinformatics to neurobiological data; and cheminformatics to chemical entities. —**informatical** *adj.*; **informatician** *n.*

informatin *see* **informofer**.

information 1 communicated or communicable factual knowledge; data; news. **2** **genetic information**. **3** (*in computing*) the results obtained by processing raw data according to programmed instructions.

informational 1 of, pertaining to, giving, or carrying information. **2** (*in biochemistry*) describing any biological macromolecule that contains or transmits **genetic information** in the form of specific sequences of nucleotides or amino acids.

information extraction *abbr.*: IE; (*in text mining*) a method for identifying specific query terms (words or phrases), and the relationships between them, within a passage of text, a complete document, or within sets of retrieved documents. By recognizing explicit concepts and relationships, and relating specific parts of a docu-

ment to the subject of interest, IE sheds light on the semantic structure of the text. *Compare* **information retrieval**.

information retrieval *abbr.*: IR; (*in text mining*) a method for identifying from a large set of documents those that relate to user-specified query terms (the method does not identify the query terms within those texts). *Compare* **information extraction**.

information retrieval software software that retrieves information relevant to a user query from unstructured text, such as occurs in the literature or in databases. For example, PubMed is a Web-based information retrieval service for NCBI's MEDLINE bibliographic database; Entrez retrieves information from an integrated set of NCBI databases; SRS (Sequence Retrieval System) is a commercial product that can be customized to search any user-defined **flat-file** databases.

information theory the quantitative theory of the coding and transmission of signals and information.

informofer a specific, 30S particle consisting of the protein **informatin**. Informofers are present in the cell nucleus, tightly packed along molecules of **heterogeneous nuclear RNA**.

informosome a cytoplasmic mRNA-carrying ribonucleoprotein particle of relatively low buoyant density. Informosomes are believed to function in the protection of mRNA from nuclease attack and in the transport of mRNA from the nucleus to the cytoplasm.

infra+ *prefix* denoting below, beneath, coming after, within. *Compare* **sub+**, **supra+**, **ultra+** (def. 1).

infradian describing any biological activity that occurs, or varies cyclically, more often than once every 24 hours. *Compare* **circadian**, **ultradian**.

infranatant 1 lying below. **2** a solid or liquid lying below a **supernatant** liquid. *Compare* **subnatant**.

infrared of, pertaining to, or being **infrared radiation**.

infrared dichroism the **dichroism** of polarized infrared radiation. It is used in studies of polypeptide structure.

infrared radiation *abbr.*: IR or i.r.; electromagnetic radiation of wavelengths in the range 730 nm to 1 mm (frequencies 300 GHz to 410 THz). This range lies between those of visible light and microwaves.

infrared spectrophotometer any instrument for **infrared spectrophotometry**.

infrared spectrophotometry the measurement of the absorption or emission of infrared radiation at particular wavelengths or frequencies. *See* **infrared spectrum**.

infrared spectrum any absorption spectrum or emission spectrum of infrared radiation. It includes photons that are absorbed or emitted during vibrational and rotational transitions in a molecule. Infrared spectra are widely used in organic chemistry to identify particular groups of atoms by their characteristic vibrational frequencies.

infuse 1 to introduce gradually, as of a solution into a vein or body cavity. **2** to make an **infusion** (def. 2).

infusion 1 the process of infusing. **2** an extract, e.g. of meat or leaves, obtained by soaking in water.

ingest to take material, e.g. food or liquid, into a cell or organism. —**ingestible** *adj.*; **ingestion** *n.*; **ingestive** *adj.*

inhibin either of the glycoproteins **inhibin** or **activin** of the transforming growth factor β family and secreted by the gonads. They participate in differentiation and growth of diverse cell types. Inhibin inhibits secretion of **follicle-stimulating hormone** by the pituitary, whereas activin stimulates its secretion. Inhibin is present in seminal plasma and follicular fluid. It consists of two subunits crosslinked by disulfide bridges. Inhibin A is a dimer of α and β_A subunits, and inhibin B is a dimer of α and β_B subunits. The β_A and β_B subunits are also constituents of activin. Their precursors are isoforms derived from the same gene. Inhibin is normally secreted throughout the menstrual cycle and during pregnancy, but not after the menopause. Plasma levels increase in certain ovarian cancers.

inhibit 1 to restrain or hinder. **2** to stop, prevent, or reduce the rate of (some process, e.g. the growth or functioning of an organism or part of an organism, or a chemical or enzymic reaction).

inhibition constant *symbol*: K_i ; the equilibrium (dissociation) constant for the reaction: $EI \rightleftharpoons E + I$. It is given by $K_i = [E][I]/[EI]$.

where E is the enzyme and I the inhibitor, the square brackets indicating concentrations.

inhibition index an inverse measure of the potency of an antimetabolite. It is the ratio of the concentration of antimetabolite that is required to inhibit the biological effect of unit concentration of corresponding metabolite.

inhibitor 1 any agent that inhibits. **2** (*in biochemistry*) any substance that inhibits an enzymic reaction. *See also* **competitive inhibition**, **non-competitive inhibition**, **uncompetitive inhibition**.

inhibitor of apoptosis protein *see* IAP.

inhibitor of differentiation *see* Id.

initial velocity or **initial steady-state rate** *symbol*: v_0 or v ; the reaction velocity in the earliest stage of an enzyme-catalysed reaction. It is given by the tangent at the origin to the curve of reaction velocity as a function of time. In practice it is often measured over the period when the initial substrate concentration has diminished by <5%.

initiation 1 the formation of **initiation complex(es)** at the start of ribosome-mediated translation of mRNA into polypeptide. **2** the first stage in carcinogenesis, in which a normal cell is converted to a pre-cancerous one. **3** the first step in a chain reaction. —**initiate** *vb.*; **initiator** *adj.*

initiation codon or **initiator codon** the codon AUG (or, sometimes in prokaryotes, GUG) that binds *N*-formylmethionyl-tRNA_f^{Met} in prokaryotes or initiator methionyl-tRNA_f^{Met} in eukaryotes, and serves as a signal for the start of polypeptide synthesis at the ribosome.

initiation complex any of the complexes formed at the start of ribosome-mediated translation of mRNA into polypeptide. They contain mRNA, initiation factors, initiator fMet-tRNA_f or Met-tRNA_f^{Met}, one or two ribosomal subunits, and sometimes GTP. *See* **initiation factor**.

initiation factor *abbr.*: IF (in prokaryotes) or eIF (in eukaryotes); any soluble protein that functions in the initiation of ribosome-mediated translation of mRNA into polypeptide. *Escherichia coli* has three principal initiation factors, each consisting of a single polypeptide chain. **IF-1** is a basic protein (9 kDa) that is a stimulator of IF-2 and IF-3. There are two forms of **IF-2**: IF-2a, which is acidic, unstable, and of 115 kDa; and IF-2b, formed by limited proteolysis of IF-2a. It is a GTP-binding protein, protects formylmethionyl-tRNA_f^{Met} from spontaneous hydrolysis, and promotes its binding to the 30S ribosomal subunits; it is also involved, with hydrolysis of GTP, in the formation of the 70S ribosomal complex. By using alternative initiation codons in the same reading frame, the eIF-2b gene is translated into three isozymes, α , β , and β' , having different N termini. **IF-3** is a basic, stable protein of 22 kDa. It binds to the 30S ribosomal subunit and shifts the equilibrium between 70S ribosomes and their subunits in favour of the free subunits, thus enhancing the availability of 30S subunits. It is also a translational repressor of its own gene. IF-1, IF-2, and IF-3 bind cooperatively to a 30S ribosomal subunit to form a 30S•IF-1•IF-2•IF-3 particle in which the three IFs are bound contiguously near the 3' end of 16S RNA in a 30S ribosomal subunit. This particle subsequently binds mRNA at a site that includes the initiation codon AUG (or GUG), initiator fMet-tRNA_f^{Met}, and GTP with concomitant release of IF-3 to form a 30S initiation complex, 30S•IF-1•IF-2•mRNA•GTP•fMet-tRNA_f^{Met}. Joining of a 50S ribosomal subunit with concomitant release of IF-1, IF-2, GDP, and P_i forms a 70S initiation complex, mRNA•70S•fMet-tRNA_f^{Met}.

Eukaryotes have more initiation factors. Many have been characterized in lysates of rabbit reticulocytes. They include: eIF-1, a monomer of 15 kDa; eIF-2, a heterotrimer of 150 kDa; eIF-3, a nonamer of 700 kDa; eIF-4A, a monomer of 49 kDa; eIF-4B, a monomer of 80 kDa; eIF-4C, a monomer of 17.5 kDa; eIF-4D, a monomer of 16.5 kDa; eIF-5, a monomer of 190 kDa; Co.eIF-2, a monomer of 22 kDa; and cap-binding protein, a monomer of 24 kDa. eIF-2, initiator Met-tRNA_f^{Met}, and GTP form a ternary complex; eIF-3 promotes ribosomal dissociation and stabilizes binding of ternary complex to a 40S ribosomal subunit to form the complex 40S•eIF-2•eIF-3•Met-tRNA_f^{Met}•GTP. Then eIF-1, eIF-4A, eIF-4B, eIF-4C, and cap-binding protein promote binding of mRNA and ATP-dependent formation of a 40S initiation complex,

40S•eIF-2•eIF-3•Met-tRNA_f^{Met}•mRNA. Factor eIF-5 is required for formation of an **80S initiation complex**, 80S•Met-tRNA_f^{Met}•mRNA, from a 40S complex, together with hydrolysis of the bound GTP and release of initiation factors. Co.eIF-2 stimulates ternary complex formation.

initiation signal 1 any of the purine-rich regions of mRNA on the 5' side of the initiation codon that serve to distinguish the latter from other similar codons. **2** any of the promoter regions of DNA on the 5' side of the start of transcription to form mRNA.

initiation switch *see* ISWI.

initiator 1 a gene product that interacts specifically with the replicator site on a replicon resulting in the initiation of a new round of DNA replication. **2** a starting point for either nucleic-acid transcription or translation. **3** a carcinogen that initiates the first stage of carcinogenesis. **4** any compound that, when added to monomer, initiates a polymerization reaction.

initiator codon *see* **initiation codon**.

initiator transfer RNA *abbr.*: tRNA_f^{Met}; any of the tRNA molecules that, when aminoacylated, specifically binds to an initiation codon (usually AUG) in mRNA at the start of ribosome-mediated translation of mRNA into polypeptide. In prokaryotes it is *N*-formylmethionyl-tRNA_f^{Met}, and in eukaryotes it is methionyl-tRNA_f^{Met}; neither is able to promote the insertion of methionine residues at internal sites.

INK4 or **CDI with 4 ankyrin repeats** any of four structurally related proteins (i.e. p15, p16, p18, and p19), each of which contains four **ankyrin** repeats. Each is a specific inhibitor of Cdk4 and Cdk6. Somatic inactivating mutations in the gene at 9p21 for CDIP16 occur in sporadic melanomas, whereas germline mutations increase the risk of melanoma and possibly other neoplasms.

innate being an essential characteristic of an organism or thing; in-born.

innate immunity an immune response in both vertebrates and invertebrates to a **pathogen** that involves the pre-existing defences of the body – the **innate immune system** – such as barriers formed by skin and mucosa, antimicrobial molecules and **phagocytes**. Such a response is not specific for the pathogen. The agents are either small proteins or peptides many of which have been detected in insects, which lack the immune system of higher animals. Examples are **cecropin** and **attractin** of the moth *Cecropia*, which kill *E.coli*. **Drosocin** kills fungi present in the fruit fly. Mammals make similar peptides called **defensins**.

innervation the nerve supply to an organ or part.

Ino *symbol* for a residue of the ribonucleoside inosine (alternative to I).

inoculate 1 to introduce cells, microorganisms, or viruses into or onto a culture medium. **2** to introduce causative agents of disease (alive, dead, or attenuated) into an animal or person for the purpose of immunization. —**inoculation**, **inoculator** *n.*; **inoculative** *adj.*

inoculum (*pl.* **inocula**) a quantity or suspension of cells, microorganisms, or viruses used to start a new culture or to infect another culture; something used to inoculate.

Ino-3',5'-P *symbol* for inosine 3',5'-phosphate.

Ino5'P *symbol* for inosine 5'-phosphate.

Ino5'PP *symbol* for inosine 5'-diphosphate (alternative to ppI).

Ino5'PPP *symbol* for inosine 5'-triphosphate (alternative to pppI).

inorganic not having the characteristics of living organisms; **not organic**.

inorganic biochemistry the branch of biochemistry concerned with the role of inorganic substances in biochemical systems. *Compare* **bioinorganic chemistry**.

inorganic chemistry the branch of chemistry dealing with the elements and all their compounds other than ones containing carbon, except for carbon itself and some simple compounds of carbon, e.g. oxides, sulfides, and cyanides.

inorganic diphosphate *symbol*: PP_i; any of the anions formed from diphosphoric acid, (HO)₂PO–O–PO(OH)₂, or any mixture of the acid and its anions. The older term **inorganic pyrophosphate** is less preferable.

inorganic phosphate or **inorganic orthophosphate** *symbol*: P_i; any

of the anions formed from [ortho]phosphoric acid, $\text{PO}(\text{OH})_3$, or any mixture of the acid and its anions.

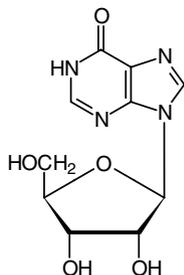

inorganic pyrophosphatase an enzyme, EC 3.6.1.1, often less precisely termed pyrophosphatase; *systematic name*: pyrophosphate phosphohydrolase. It catalyses the hydrolysis of pyrophosphate to two molecules of orthophosphate.

inorganic pyrophosphate a less preferred term for **inorganic diphosphate**.

iNOS see **nitric-oxide synthase**.

inosinate 1 either the mono- and/or the di-anion of **inosinic acid**. **2** any mixture of the acid and its anions. **3** any salt or ester of inosinic acid.

inosine *symbol*: I or Ino; hypoxanthosine; hypoxanthine riboside; 9- β -D-ribofuranosylhypoxanthine; a nucleoside found free, especially in meat, sugar beet, and yeast, and in the anticodons of some transfer RNAs. It may be formed by the action of adenosine deaminase (EC 3.5.4.4) in the first step of the breakdown of adenosine to uric acid, and it occurs as an intermediate in the recycling of adenosine and inosine 5'-phosphate by **salvage pathways**.

inosine 3',5'-(cyclic)phosphate or **inosine 3',5'-cyclophosphate** see **inosine 3',5'-phosphate**.

inosine 5'-diphosphate *symbol*: Ino5'PP or ppI; *recommended name* for inosine diphosphate (*abbr.*: IDP), 5'-diphosphoinosine, 5'-inosinyl phosphate, inosine 5'-(trihydrogen diphosphate). It is an intermediate in the formation of inosine 5'-triphosphate from inosine 5'-phosphate.

inosine monophosphate *abbr.*: IMP; an alternative name for any **inosine phosphate**, but particularly for **inosine 5'-phosphate**, especially when its distinction from inosine (5')-diphosphate and inosine (5')-triphosphate requires emphasis.

inosine-5'-monophosphate dehydrogenase see **IMP dehydrogenase**.

inosine phosphate inosine monophosphate (*abbr.*: IMP); any phosphoric monoester or diester of inosine. Of the three possible monoesters – the 2'-phosphate, the 3'-phosphate, and the 5'-phosphate – only **inosine 5'-phosphate** is of any importance (the locant being omitted if no ambiguity may arise). The only diester of significance is **inosine 3',5'-phosphate**.

inosine 3',5'-phosphate *symbol*: Ino-3',5'-P; *the recommended name* for cyclic inosine 3',5'-monophosphate (*abbr.*: 3',5'-cyclic IMP or cyclic IMP or cIMP), inosine 3',5'-cyclophosphate, inosine 3',5'-(cyclic)phosphate; a monophosphoric diester of inosine. It is a cyclic nucleotide similar in structure and metabolism to **adenosine 3',5'-phosphate** (i.e. cyclic AMP) but only rarely encountered.

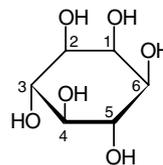

inosine 5'-phosphate or **5'-inosinic acid** or **5'-phosphoinosine** or **5'-O-phosphoinosine** *symbol*: Ino5'P; *alternative recommended names* for inosine monophosphate (*abbr.*: IMP), inosine 5'-(dihydrogen phosphate), hypoxanthine ribonucleotide. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation.) It is the initial biosynthetic product containing an intact purine nucleus, its immediate precursor being 4-carbamoyl-5-formamidoimidazole riboside 5'-phosphate. Hence IMP is a key intermediate in the biosynthesis of all other purine nucleotides and in the formation of purine nucleosides and free purines. In addition, resynthesis of IMP from hypoxanthine can be effected via a **salvage pathway** by the action of hypoxanthine phosphoribosyltransferase (EC 2.4.2.8) (see **phosphoribosyltransferase**).

inosine 5'-triphosphate *symbol*: Ino5'PPP or pppI; *the recommended name* for inosine triphosphate (*abbr.*: ITP), 5'-triphosphoinosine, 5'-inosinyl diphosphate, inosine 5'-(tetrahydrogen triphosphate). ITP can substitute for adenosine 5'-triphosphate or guanosine 5'-triphosphate in certain enzymic reactions. It is formed from inosine 5'-diphosphate by transfer of the terminal phosphoric residue from adenosine 5'-triphosphate through the action of nucleoside-diphosphate kinase (EC 2.7.4.6).

inosinic acid *the trivial name* for any phosphoric monoester of inosine. The position of the phosphoric residue on the ribose moiety of a given ester may be specified by a prefixed locant (see **inosine phosphate**). However, 5'-inosinic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-Inosinic acid is also an alternative recommended name for **inosine 5'-phosphate**.

inosinyl the inosine [mono]phospho group; the acyl group derived from **inosinic acid**.

inositol 1 *symbol*: Ins; *the common name* for the cyclitol *myo*-inositol (formerly called *meso*-inositol or *i*-inositol or bios I or muscle sugar); 1,2,3,5/4,6-cyclohexanehexol; a growth factor for some animals and microorganisms, widely distributed in nature. Inositol occurs free, as various phosphates, or as a constituent of certain phospholipids (see **phosphatidylinositol**); in plants it also occurs as its hexaphosphate phytate. Note: whereas *myo*-inositol itself is achiral, its phosphorylated derivatives are chiral and the numbering of their carbon atoms can be confusing. For a proposed solution of the problem, see **Agranoff's turtle**. **2** *generic name* for any member of a subclass of cyclitols comprising the nine possible 1,2,3,4,5,6-cyclohexanehexols, of which inositol (def. 1) is the most prevalent and most important.

inositol-1,3-bisphosphate 3-phosphatase EC 3.1.3.65; an enzyme that hydrolyses *D*-*myo*-inositol 1,3-bisphosphate to *D*-*myo*-inositol 1-monophosphate and orthophosphate.

inositol-1,4-bisphosphate 1-phosphatase EC 3.1.3.57; *systematic name*: *D*-*myo*-inositol-1,4-bisphosphate 1-phosphohydrolase; *other name*: inositol polyphosphate 1-phosphatase; an enzyme that hydrolyses *D*-*myo*-inositol 1,4-bisphosphate to *D*-*myo*-inositol 4-phosphate and orthophosphate.

inositol glycan any compound that consists of inositol linked to a glycan. The best known is the one that forms part of the membrane anchor of PIG-tailed proteins. It is rapidly released by insulin-sensitive cells *in vitro* in response to insulin and by the action of phosphoinositol-specific phospholipase C. Its physiological role is unclear.

inositol phosphate any phosphoric ester of an inositol, but normally referring to the esters of *myo*-inositol (*abbr.*: Ins). Of particular interest are those formed by the hydrolysis of membrane phosphoinositides following activation of phosphoinositide-specific phospholipase C (see **phospholipase**). The generalized abbreviation for phosphorylated *myo*-inositols follows the convention Ins(n , numbers of the carbons bearing phosphorylated hydroxyls) P_x , where P_x indicates the number of phosphates. They include inositol 1,4,5-trisphosphate (*abbr.*: Ins(1,4,5) P_3), formed by phospholipase C action on phosphatidylinositol 4,5-bisphosphate. Ins(1,4,5) P_3 is important in the **phosphatidylinositol cycle**. It can be phosphorylated to Ins(1,3,4,5) P_4 , which is also physiologically active in calcium metabolism. Other inositol phosphates are intermediates in the degradation of Ins(1,4,5) P_3 and Ins(1,3,4,5) P_4 . Ins(1,4,5) P_3 is hydrolysed to Ins(1,4) P_2 , which is hydrolysed to Ins(4) P and thence to Ins. Ins(1,3,4,5) P_4 is hydrolysed to Ins(1,3,4) P_3 , which is hydrolysed to

either Ins(1,3) P_2 or Ins(3,4) P_2 , these being hydrolysed to Ins(1) P or Ins(3) P respectively and thence to Ins.

inositol-1,3,4,5-tetrakisphosphate 3-phosphatase EC 3.1.3.62; an enzyme that hydrolyses D-*myo*-inositol 1,3,4,5-tetrakisphosphate to D-*myo*-inositol 1,4,5-trisphosphate and orthophosphate.

inositol-1,4,5-trisphosphate 1-phosphatase EC 3.1.3.61; an enzyme that hydrolyses D-*myo*-inositol 1,4,5-trisphosphate to D-*myo*-inositol 4,5-bisphosphate and orthophosphate.

inositol-1,4,5-trisphosphate 5-phosphatase EC 3.1.3.56; systematic name: D-*myo*-inositol-1,4,5-trisphosphate 5-phosphohydrolase; other names: inositol trisphosphate phosphomonoesterase; inositol polyphosphate 5-phosphatase; 5PTase; an enzyme that hydrolyses D-*myo*-inositol 1,4,5-trisphosphate to D-*myo*-inositol 1,4-bisphosphate and orthophosphate. The enzyme has two types; type I (but not type II) hydrolyses inositol 1,3,4,5-tetrakisphosphate to inositol 1,3,4-trisphosphate; neither enzyme acts on the latter or on inositol 1,4-bisphosphate.

inositol trisphosphate receptor see **IP₃ receptor**.

inosyl any chemical group formed by the loss of a 2', 3', or 5'-hydroxyl group from the ribose moiety of **inosine**.

inotropic influencing contractility of muscles, especially cardiac muscle.

Ins symbol for a residue of the cyclitol 1-D-*myo*-inositol (see **inositol** (def. 1)).

Inscuteable a protein of *Drosophila* that is involved in differentiation of a neuroblast into a ganglion mother cell. It is present in the apical cortical crescent and is essential for correct segregation of the basal cortical crescent from the former into the latter cell.

INSD abbr. for International Nucleotide Sequence Database; see **composite database**.

insect any small air-breathing arthropod of the class Insecta, typically having a segmented body with an external, chitinous covering, three pairs of legs, and in most groups two pairs of wings.

insecticide any substance or agent that kills insects. —**insecticidal** *adj.*

(insect) moulting hormone (or *US*) **(insect) molting hormone** a common name for **ecdysterone**.

insectorubin any red or red-brown eye pigment of insects derived from oxidation products of tryptophan. See also **ommin**.

insectoverdin any green pigment of insects formed of mixtures of carotenoids and biliverdin.

insert (*in genetics*) a fragment of DNA that has been linked into a cloning vector. The term can also be used as a modifier as, e.g., in **insert DNA**.

insertional inactivation the inactivation of a gene in a plasmid or other cloning vector by insertion of foreign DNA at an endonuclease site. If the gene is *lacZ* its inactivation can be detected by the inability of bacterial colonies containing the recombinant plasmid to hydrolyse **X-gal**. Such colonies remain white whereas plasmids religated without an insert give blue colonies.

insertional mutagenesis the induction of a mutation by the insertion of DNA into a gene using recombinant DNA techniques. One approach, known as restriction enzyme-mediated integration (REMI), utilizes a plasmid that is cut with a restriction enzyme. Then the cut plasmid, together with the restriction enzyme, is introduced into cells (e.g. *Dicotyostelium*) by electroporation. The restriction enzyme cuts the genomic DNA at sites into which the plasmid can integrate through its **sticky ends**. If the plasmid contains a suitable marker, transformants can be isolated. The gene affected can be identified because it is effectively tagged with the plasmid. If the plasmid also contains an additional marker conferring drug resistance, the gene from the transformant can be readily cloned.

insertion mutation any mutation caused by insertion of an extranumerary nucleotide residue between two successive nucleotide residues in a DNA molecule.

insertion sequence abbr.: IS; see **signal sequence**, **transposon**.

insertion vector (*in recombinant DNA technology*) any **vector** (def. 3) that has been cut with a restriction enzyme having a single target site in the centre of the vector, so that two 'arms' are generated between which foreign DNA may be inserted.

insertosome an 800–1400 bp stretch of DNA that can insert itself

randomly into the chromosome of *Escherichia coli*, thereby causing polar mutations analogous to those caused by phage Mu-1.

inside-out vesicle any vesicle formed from disrupted cell or other membranes that has sealed up so that the face of the membrane that was originally on the outside is now on the inside.

in silico *Latin* (*of any biological process, reaction, or experiment*) made to occur by means of a computer (e.g. a simulation in the e-cell). Literally, it means 'in silicon'. Compare **in vitro**, **in vivo**.

in silico screening an alternative name for **combinatorial chemistry**.

in situ *Latin* in the normal, natural, original, or appropriate position.

in situ hybridization or **hybridization in situ** a technique that uses labelled nucleic acid probes to reveal the location of genes on chromosomes, or of specific mRNA molecules within tissue sections, small organisms, or embryos. See **fluorescence in situ hybridization**, **hybridization analysis**.

insolubilize or **insolubilise** to render **insoluble** (def. 1), especially by coupling covalently to an insoluble matrix. —**insolubilization** or **insolubilisation** *n*.

insoluble 1 incapable of being dissolved (in water unless otherwise specified); of extremely low solubility. 2 incapable of being solved; having no solution.

Ins(3,4) P_2 symbol for 1D-*myo*-inositol 3,4-bisphosphate.

Ins(1,3,4) P_3 symbol for 1D-*myo*-inositol 1,3,4-trisphosphate.

Ins(1,4,5) P_3 symbol for 1D-*myo*-inositol 1,4,5-trisphosphate.

Ins(1,3,4,5) P_4 symbol for 1D-*myo*-inositol 1,3,4,5-tetrakisphosphate.

instructive theory of immunity a theory ascribing to an antigen the function in immunity of instructing or directing uncommitted cells to form new antibodies that reflect the nature of the antigen itself. Compare **selective theory of immunity**.

insulate to prevent, or reduce, the passage of electricity, heat, or sound to or from (something) by interposition of a (relevant) non-conducting material.

insulaxin a synthetic porcine insulin that instead of the A chain Ile¹⁰, and B chain Ser⁹, His¹⁰, and Glu¹³ contains, respectively, Gly, Arg, Glu, and Arg, as in porcine **relaxin**. Unlike the native insulin, it binds to the porcine relaxin receptor.

insulin or (*formerly*) **insuline** the hypoglycemic, antidiabetic, and anabolic polypeptide hormone of the endocrine portion of the mammalian pancreas or of homologous organs of lower vertebrates. In mammals, it is elaborated in the B cells of the islets of Langerhans and stored within them in the B granules prior to release by exocytosis. Insulin is a slightly acidic protein that readily aggregates to form dimers, hexamers, and higher multimers. It is very poorly soluble in aqueous media around its isoelectric point (pH ≈ 5.4), especially in the presence of certain divalent metal ions, typically Zn²⁺, with which it can form crystals, usually containing two or four metal ions per insulin hexamer, depending on conditions. It does, however, dissolve without denaturation in organic solvents in an acid medium, a property that can be exploited in its isolation. The monomer of insulin is one of the smallest known proteins, with M_r values such as 5733 (bovine), 5777 (porcine), or 5807 (human). Bovine insulin was the first protein to have its primary sequence determined, by British biochemist Frederick Sanger (1918–), in 1955. The sequences of a large number of insulins are now known, all of which consist of two polypeptide chains, commonly termed the **A chain** and the **B chain**, with three disulfide bridges formed between half-cystine residues; two of these bridges are inter-chain, forming A7–B7 and A19–B20 links, and the third is intra-chain, linking positions A6 and A11 to form a heterodetic ring in the A chain. The numbers of amino-acid residues vary slightly with the species of origin, commonly being 21 and 30 in the A and B chains, respectively; six amide groups are present per molecule of the monomer if insulin is carefully isolated. The three-dimensional structure is known: chains A and B have two motifs each. Insulin is structurally related to **relaxin** and **insulin-like growth factor**. Insulin is biosynthesized by post-translational modification of its single-chain precursor **preproinsulin**. In preproinsulin, residues 1–24 are the signal sequence. When this is removed, proinsulin is formed. In the Golgi apparatus, prohormone convertases PC2 and PC3 cleave proinsulin on the carboxyl side of a pair of basic amino-acid

residues (Arg⁵⁵-Arg⁵⁶ and Lys⁸⁸-Arg⁸⁹). This excises the C peptide (residues 57–87), leaving the A and B chains (two Arg residues (55 and 56) must first be cleaved from the B chain by carboxypeptidase H for the mature B chain to be formed). Residues 55–87 are known as the connecting peptide. Human insulin consists of 110 amino acids; the A chain is derived from residues 90–110, and the B chain from residues 25–54.

Insulin stimulates glucose uptake by muscle and adipose tissue, and promotes glycogenesis, lipogenesis, and synthesis of protein and nucleic acid. Deficiencies in the secretion or action of insulin in humans result in the overproduction and increased urinary excretion of glucose (see **glucose-tolerance test**, **diabetes mellitus**); continuing therapeutic administration of insulin is necessary in type I (insulin-dependent) diabetes mellitus. Commercial insulin for therapeutic use is extracted mostly from bovine or porcine pancreas; human insulin is now also being made by recombinant DNA technology. The international unit for insulin is defined as the activity contained in 0.04167 mg of the Fourth International Standard for Insulin, Bovine and Porcine, for Bioassay (which is defined as crystalline zinc insulin derived from a mixture of 52% bovine insulin and 48% porcine insulin).

insulinase EC 3.4.99.45; *other names*: insulin-degrading enzyme; insulin protease; insulysin. An enzyme that progressively cleaves a number of peptide bonds in insulin, but only Arg¹⁷-|-Arg¹⁸ in glucagon and some other unrelated hormones and cytokines. It is a zinc thioendopeptidase of the inverzincin family and is widely expressed in mammalian tissues (including some that are not insulin-sensitive). It shows little sequence homology with classical metallo- or cysteine proteases.

insulin-dependent diabetes mellitus *abbr.*: IDDM; *see* **diabetes mellitus**.

insulin-like growth factor *abbr.*: IGF; any member of a group of polypeptides that are structurally homologous to **insulin** and share many of its biological activities but are immunologically distinct from it; they are mitogens of the insulin/relaxin family. They include substances now named insulin-like growth factor-I (IGF-I), which is a monomer of 70 amino acids, and insulin-like growth factor-II (IGF-II), which is a monomer of 67 amino acids; together these were formerly known as **nonsuppressible insulin-like activity** (NSILA). The insulin-like growth factors also include **somatomedin C**, which is IGF-I, and possibly also somatomedins A₁ and A₂, and **multiplication-stimulating activity**. They appear to be more potent than insulin as growth-promoting factors but less potent in stimulating glucose utilization. Brain IGF is a truncated form of IGF-I, in which the N-terminal tripeptide sequence is lacking. *See also* **insulin-related growth factor**, **somatomedin**.

insulin-like growth factor binding protein *abbr.*: IGFBP; any of several proteins that bind insulin-like growth factors (IGFs), and are found in serum, amniotic, and other body fluids, and in conditioned media from a variety of cell types. They are believed to prolong the half-life, and regulate the endocrine effects, of IGFs. Six IGFBPs (IGFBP-1 to -6) have been identified in humans, their complementary DNA having been cloned and sequenced. IGFBP-1 was originally identified as a placental protein, placental protein-12 (PP-12) and as α -1 pregnancy-associated globulin; it is a non-glycosylated protein, M_r 25 000; IGFBP-2 has been identified in human and rat central nervous systems; it is a non-glycosylated protein, M_r 31 000. IGFBP-1 and IGFBP-2 both have the RGD motif, a recognition site for **integrins**. IGFBP-3 is the principal IGFBP in human serum; it is a glycoprotein, M_r 28 500, and circulates as a complex with IGF peptide (γ subunit). For IGFBP-5, *see* **skeletal growth factor**.

insulin-like growth factor receptor an integral membrane protein that binds and mediates the effects of **insulin-like growth factor** (IGF). **IGF-I receptor** is a glycoprotein of composition $\alpha_2\beta_2$, the subunits being linked by disulfide bonds. It has an extracellular ligand-binding domain and a cytoplasmic protein tyrosine kinase domain. It is widely expressed in embryonic but not in adult tissues. **IGF-II receptor** is the cation-independent **mannose-6-phosphate receptor**. It mediates endocytosis and degradation of excess IGFII. The insulin receptor is the main receptor for IGFII.

insulinogenesis the formation of **insulin**.

insulinogenic resulting from the administration of **insulin**.

insulinoma any neoplasm originating in the B cells of the pancreatic islets (or sometimes from nonislet tissue), that autonomously secretes insulin and/or biosynthetic precursors of insulin. Such lesions are frequently recognized by their metabolic consequences.

insulinotropic stimulating **insulin** secretion.

insulinotropic effect *see* **gastric inhibitory peptide**.

insulinotropin a peptide containing residues 7–37 of glucagon-like peptide I, present with glucagon in preproglucagon. It is a potent stimulator of insulin release from the perfused rat pancreas. *See* **glucagon-like insulinotropic peptide**.

insulin receptor a type I membrane protein with tyrosine kinase (EC 2.7.1.112) activity. The protein is derived from a precursor; after being transported from the endoplasmic reticulum to the Golgi apparatus, the single glycosylated precursor is further glycosylated and then cleaved to α and β chains. In the plasma membrane the receptor is a disulfide-bonded heterotetramer, $\alpha_2\beta_2$; the α chains are entirely extracellular, while each β chain has one transmembrane domain. The ligand binds to the α -subunit extracellular domain and the kinase is associated with the β -subunit intracellular domain; it is partly regulated by autophosphorylation. Associated diseases include various forms of insulin resistance, including type 2 **diabetes mellitus** and **leprechaunism**. The human precursor protein consists of 1382 amino acids; amino acids 28–762 form the α subunit, while 763–1382 form the β subunit.

insulin receptor substrate *abbr.*: IRS; any of four proteins (IRS-1, -2, -3, and -4) that bind the activated tyrosine kinase domain of the insulin receptor and become phosphorylated by it. They share certain structural features: in the N-terminal region, a **plekstrin** homology region (\approx 100 residues that bind phosphatidylinositides) and a phosphotyrosine binding region (also \approx 100 residues); and in the C-terminal region multiple tyrosine phosphorylation sites. All contain binding sites for SH2 domains in other proteins. Two polymorphisms in IRS-1 (1242 residues) are associated with a subset of diabetes mellitus type 2 patients. Mouse knockouts of IRS-1 and IRS-2 develop insulin resistance.

insulin-related growth factor (*sometimes*) any vertebrate and invertebrate protein or polypeptide hormone or growth factor (including **relaxin**, **nerve growth factor**, **insulin-like growth factors**, silkworm prothoracicotrophic hormone, and possibly others) that shares with insulin certain features of primary and three-dimensional structure and may also display some similarities to insulin as a regulator of growth and/or metabolism.

insulin resistance a decreased ability of insulin to produce its biological effects across a wide range of concentrations. It is usually associated with hyperinsulinemia and is promoted by obesity, a sedentary lifestyle, hyperlipidemia, hypertension, and increasing age. In the majority of cases its molecular basis is largely unknown. It is usually reversed by exercise, weight loss, and diet. *See* **hyperinsulinemia syndrome**.

insulin-tolerance test a sensitive and accurate test of the integrity of the hypothalamic-pituitary-adrenal axis and its ability to respond to stress, and also of somatotropin responsiveness. The test is performed after an overnight fast with measurement of plasma cortisol, glucose, and somatotropin levels before and periodically after intravenous administration of insulin. The hypoglycemia induced by insulin elicits a potent stress response via the central nervous system, stimulating the release of **corticotropin releasing hormone** and consequently, of **corticotropin**.

Int the product of phage gene *int*, involved in the integration of phage DNA into host DNA during transition from the lytic to the lysogenic states. *Compare* **Int-2**. *See also* **retroregulation**.

Int-2 an oncogene first identified following the integration of mouse mammary tumour virus into the mouse DNA. Its product is a **fibroblast growth factor** (FGF3). *Compare* **Int**.

integer any rational whole number.

integral 1 of, or being an essential part of a whole; entire, complete. 2 (*in mathematics*) of, or denoted by, an **integer**; of or involving an **integral** (def. 3). 3 (*in mathematics*) the sum of a large number of infinitesimally small quantities, denoted \int , summed either between specified limits (**definite integral**) or within indeterminate limits (**indefinite integral**).

integral (cell membrane) protein or **intrinsic protein** any protein that can only be dissociated from a cell membrane by drastic treatment with a reagent such as detergent, bile salt, protein denaturant, or organic solvent. Such proteins have one or more domains that traverse the cell membrane. *Compare* **peripheral (cell membrane) protein**.

integrase a protein of lambdoid phages that catalyses integration of phage DNA during establishment, probably by forming a transient DNA-protein link. The same enzyme is one subunit of the **excisase** activity that reverses this; the other subunit is the Xis protein, known as **excisionase**.

integrate **1** to combine or be combined into a whole; to complete (something imperfect) by the addition of parts. **2** (*in mathematics*) to find the **integral** (def. 3) of (quantities, expression, etc.). —**integrable**, **integrative** *adj.*; **integrability** *n.*

integrated rate equation a general expression for the interpretation of a single enzyme-catalysed reaction. The expression for the velocity of a reaction at time t is:

$$v = d[P]/dt = V([S]_0 - [P]) / \{K_m + ([S]_0 - [P])\}.$$

This can be integrated with respect to time to give:

$$Vt = [P]_t + K_m \ln \{ [S]_0 / ([S]_0 - [P]_t) \},$$

or

$$\ln \{ [S]_0 / ([S]_0 - [P]_t) \} / t = V / K_m - [P]_t / K_m t,$$

where $[S]$ and $[P]$ are the concentrations of substrate and product, v is the velocity of the reaction, V is the limiting rate, and K_m is the Michaelis constant. The subscripts indicate the concentrations at zero time and at time t . A plot of $\ln \{ [S]_0 / ([S]_0 - [P]_t) \} / t$ against $[P]_t / t$ will have a slope of $-1/K_m$ and an intercept of V/K_m .

integration **1** the act or process of uniting or adding parts to make a whole. **2** the process of determining and/or indicating the mean value or total sum of (some physical quantity, area, etc.). **3** (*in mathematics*) the process of determining the **integral** (def. 3) of a function or a variable. *Compare* **differentiation**. **4** (*in genetics*) the act or process of forming a **cointegrate**.

integrative genomics the study of complex interactions between genes, organisms, and the environment.

integrator any device (mechanical or electronic) or any person that determines the value of an **integral** (def. 3).

integrin any member of the large family of transmembrane proteins that act as receptors for **cell-adhesion molecules**. Integrins are heterodimeric molecules in which the α and β subunits are noncovalently bonded. The subunits are named from α_1 to α_8 , α_L (for **LFA-1**), α_M (for **Mac-1**), α_v (for **vitronectin** receptor), and from β_1 to β_7 . Both subunits penetrate the cell-membrane lipid bilayer; the α subunit has four Ca^{2+} -binding domains on its extracellular chain, and the β subunit bears a number of cysteine-rich domains extracellularly. The integrins are grouped into families: the VLA family, having the β_1 subunit; the LEUCAM family, which includes LFA-1 and Mac-1, having the β_2 subunit; and a group of other integrins having subunits β_3 – β_8 . The type of integrin expressed on the cell surface determines which adhesion molecules (and thus which other cells) the cell will bind, and can be varied in different circumstances. For example, transforming growth factor- β increases expression of $\alpha_1\beta_1$, $\alpha_2\beta_1$, $\alpha_3\beta_1$, and $\alpha_5\beta_1$ integrins on fibroblasts and the $\alpha_v\beta_3$ integrin on fibroblasts and osteosarcoma cells; interleukin-1 β enhances β_1 expression on osteosarcoma cells; and in response to wounding, the keratinocyte, which normally expresses integrin $\alpha_6\beta_4$, will express $\alpha_5\beta_1$ (VLA-1, the fibronectin receptor) so that the keratinocyte will then migrate over fibronectin in the cell matrix, thus covering the wound. *See also* **adhesion molecules** (for details of the integrins to which they bind).

intein an internal peptide sequence of a protein precursor that is spliced out by transpeptidation during processing to form the mature protein. The peptide sequences that are spliced together are termed **exteins**. The terms are derived, respectively, by analogy from **introns** and **exons**.

intensify (*in photography*) to increase the opacity (of a film or plate). —**intensification**, **intensifier** *n.*

intensifying screens thin sheets of calcium tungstate used in autoradiographic detection of strong beta-emitting nuclides such as

^{32}P . Strong beta-particles pass through X-ray film and cause the screen to emit blue light, which is captured by silver halide grains in the film. Sensitivity of detection is increased fivefold when the film is exposed at $-70^\circ C$ because the decay of the latent image is decreased.

intensity (*in physics*) the magnitude of an energy flux, field strength, or force. *See* **luminous intensity**, **radiant intensity**.

intensity millicurie an obsolete name for **sievert** (def. 2).

intensive property any of the properties of a substance or object that describe a specific characteristic of the substance or object in a given state. Intensive properties are independent of the amount of the substance or the size of the object being considered, e.g. density, specific volume, temperature, etc. *Compare* **extensive property**. *See also* **intensive**.

inter+ *comb. form* signifying between, within, or among. *Compare* **intra-**

interaction **1** any reciprocal or mutual action or effect. **2** (*in physics*) the transfer of energy between elementary particles, between particles and a field, or between two or more fields. —**interact** *vb*.

interaction broadening the concentration-dependent broadening of lines in an electron spin resonance spectrum caused by magnetic interactions between paramagnetic molecular or atomic species.

interactive (*of two or more forces, fields, processes, etc.*) acting reciprocally or in close and/or continuing relation with each other; interacting.

interallelic complementation interaction between products of two mutant alleles to form a functional protein. It can occur in the case of multimeric proteins, for which subunits are encoded by two alleles. If products from only one mutant allele compose the protein, an inactive protein results, but in certain cases, if the products from the two alleles (each of which codes for an inactive protein) are combined in the protein, an active protein results. This was first shown in *in vitro* experiments by taking two inactive proteins of alleles encoding glutamate dehydrogenase (NADP $^+$), and recombining them by freezing and thawing in the presence of NaCl to form an active enzyme. There is some evidence that it can also occur *in vivo*.

interband any DNA-poor region between two (DNA-rich) bands in a polytene chromosome.

intercalary deletion *see* **deletion**.

intercalary DNA *abbr.*: iDNA; moderately repetitive DNA sequences occurring between structural genes in chromosomal DNA.

intercalation (*in molecular biology*) the insertion of additional material between the parts of an existing series, especially the insertion of molecules of antibiotic substances (e.g. actinomycin D) or acridine dyes (e.g. proflavine) between adjacent base pairs in a DNA duplex, thereby interfering with replication, etc. —**intercalate** *vb*; **intercalation** *n.*; **intercalary** or **intercalative** *adj.*

intercalator or **intercalating agent** (*in molecular biology*) any substance capable of being intercalated.

intercellular between cells. *Compare* **intracellular**.

intercept (*in mathematics*) a point at which two figures intersect; the point at which a line, curve, or surface cuts a coordinate axis.

interchain (*of any interaction or linkage*) between two chains of a biopolymer.

interconvertible enzyme any enzyme that exists in at least two well-defined reversibly convertible forms, produced by covalent modifications of amino-acid side chains under biological conditions (covalent modifications occurring as intermediates in the catalytic process are excluded). *Compare* **isoenzyme**.

intercrine an alternative name for **chemokine**.

interface **1** any surface forming a common boundary between two bodies, molecules, liquids, or phases. **2** any device, instrument, or method connecting two systems or processes; used especially of connections between computer systems. **3** to connect with or by an **interface** (def. 2). —**interfacial** *adj.*

interfacial tension the surface tension occurring at the interface between two mutually saturated liquids that tends to contract the area of the interface.

interference **1** (*in physics*) the process in which two or more wave

trains of the same frequency and phase are superimposed to form a wave train in which there are alternate bands (called **interference fringes**) of no energy (due to **destructive interference**) or higher energy than that of the individual wave trains (due to **constructive interference**). **2** (*in virology*) the partial or complete prevention of the replication of one virus in a cell or tissue by the concomitant interaction between the given cell or tissue and another virus.

interference (light) filter a type of (light) filter with which a transmitted band-width of 10–20 nm can be obtained with a peak transmission of about 40%. It is possible to make interference filters in which the position of the centre of the transmitted band can be set within 1–2 nm.

interference fringe *see* **interference** (def. 1).

interference optics a system of optics, based on the Rayleigh interferometer, that is sometimes fitted to analytical ultracentrifuges. A double-sector ultracentrifuge cell is used, one sector containing only solvent and the other the solution being examined. The pattern of interference fringes produced by light passing through both sectors is a function of the refractive index at each point in the cell, each fringe tracing a curve of the refractive index against distance. Interference optics allows smaller changes in concentration to be detected than is possible by the **Schlieren method**.

interfering RNA *see* **RNA interference**.

interferogram a photographic record of a pattern of interference fringes.

interferometer an instrument that divides a beam of electromagnetic radiation into a number of beams and reunites them to produce **interference fringes**. It is useful for accurate measurement of the wavelength of the radiation, examination of the hyperfine structure of spectral lines, the testing of the flatness of surfaces, etc. —**interferometric adj.**; **interferometrically adv.**; **interferometry n.**

interferon *abbr.*: IFN; any member of a group of proteins that form a closely related group of non-viral proteins, M_r in the range 15 000 to 30 000, that are produced and liberated by animal cells following exposure to a variety of inducing agents; they are not normally present in uninduced cells. They exert non-specific, antiviral activity, at least in homologous cells, through cellular metabolic processes involving the synthesis of both RNA and protein. Viruses are the most potent inducing agents, but interferons can also be induced by exposure of cells to a wide variety of microorganisms, bacterial endotoxins, phytohemagglutinins, and other substances. Interferons do not prevent viral penetration into cells, but induce within the cells a complex of inhibitors of protein synthesis that block translation of viral mRNA, but not the cell's own mRNA. Among the interferon inhibitors are a protein kinase, which phosphorylates an initiation factor in protein synthesis, and an oligonucleotide synthetase, which catalyses the synthesis of pppA2'p5'A2'p5'A (*abbr.*: 2,5-A) — this trinucleotide activates a latent cellular endonuclease that degrades the viral mRNA. Interferons are classified into three types. **IFN- α** (*formerly* leukocyte interferon) comprises many examples; they are produced by macrophages, have antiviral activities, and stimulate production of two enzymes: a protein kinase and an oligoadenylate synthetase; they exist as monomers. **IFN- β** (*formerly* fibroblast interferon) has antiviral, antibacterial, and anticancer activities. It is related to the α family. **IFN- γ** (*formerly* immune interferon) is produced by lymphocytes activated by specific antigens or mitogens. In addition to antiviral activity, it has important immunoregulatory functions: it is a potent activator of macrophages, it has antiproliferative effects on transformed cells, and can potentiate the antiviral and antitumour effects of the type I interferons (α and β). It is a glycoprotein and exists as a homodimer. Interferons are produced commercially either by *in vitro* culture of human leukocytes or by recombinant DNA or RNA technology, γ interferon requiring a system that effects glycosylation.

interferon- γ receptor *abbr.*: I γ -R; a widely expressed membrane receptor that consists of two single-pass transmembrane subunits that dimerize on binding of interferon γ (IFN- γ). One (I γ -R1) is a glycoprotein of 472 amino acids, binds IFN- γ , becomes phosphorylated intracellularly, and activates JAK1 and STAT 1. The other (I γ -R2) activates JAK2. Ligand binding also stimulates membrane sphingomyelinase to release ceramide. Several mutations in I γ -R1

result in a rare autosomal recessive susceptibility to weakly pathogenic mycobacteria.

intergenic DNA regions of chromosomes between contiguous genes, whether or not they are encoded on the same or complementary strands of the duplex.

intergenic suppression *see* **suppression**.

interjacent RNA a 26S single-stranded RNA found in cells infected with certain togaviruses, e.g. Semliki forest virus. It codes for all the virus coat proteins.

interleukin *abbr.*: IL; any member of a heterogeneous group of **cytokines** that have the ability to act as signalling molecules between different populations of leukocytes. Several classes have been defined; each is designated by a suffixed arabic numeral: e.g., **interleukin 1** (IL-1), **interleukin 2** (IL-2), etc.

interleukin 1 *abbr.*: IL-1; *former names*: lymphocyte-activating factor (LAF); mitogenic protein (MP); helper-peak-1 (HP-1); T-cell-replacing factors III and m (TRF-III; TRF-m); B-cell-activating/differentiation factor (BAF; BDF). An interleukin of M_r 12 000–18 000, produced mainly by activated macrophages. It is not able to promote and maintain *in vitro* long-term cultures of T cells, but stimulates thymocyte proliferation by inducing **interleukin 2** release. It is involved in the inflammatory response, and is identified as an endogenous pyrogen.

interleukin 2 *abbr.*: IL-2; *other names*: thymocyte-stimulating factor (TSF); thymocyte mitogenic factor (TMF); T-cell growth factor (TCGF); co-stimulator; killer-cell helper factor (KHF); secondary cytotoxic T-cell-inducing factor (SCIF). An interleukin of M_r 30 000–35 000, produced by T cells in response to antigenic or mitogenic stimulation. Translocation involving the IL-2 gene causes one form of acute lymphoblastic leukemia. IL-2 promotes and maintains *in vitro* long-term cultures of T cells.

interleukin 3 *abbr.*: IL-3; *other names*: multipotential colony-stimulating factor; hematopoietic growth factor; P-cell-stimulating factor; mast-cell growth factor. A class of interleukins that are granulocyte/macrophage colony-stimulating cytokines; they act in hematopoiesis by controlling the production, differentiation and function of granulocytes and monocytes/macrophages. They are glycoprotein monomers.

interleukin 4 *abbr.*: IL-4; *other names*: B-cell stimulatory factor 1; lymphocyte stimulatory factor 1. An interleukin that participates in several B-cell activation processes, as well as those of other cell types. It is a co-stimulator of DNA synthesis, and is a glycoprotein.

interleukin 5 *abbr.*: IL-5; *other names*: T-cell-replacing factor; eosinophil differentiation factor. An interleukin that induces terminal differentiation of late-developing B cells to immunoglobulin-secreting cells. It is a homodimer, with subunits linked by a disulfide bond.

interleukin 6 *abbr.*: IL-6; *other names*: B-cell stimulatory factor 2; interferon β -2; hybridoma growth factor. An interleukin that induces myeloma and plasmacytoma growth, and nerve-cell differentiation. In hepatocytes, it induces acute-phase reactants. It is a glycoprotein.

interleukin 7 *abbr.*: IL-7; *other name*: hematopoietic growth factor. An interleukin that stimulates proliferation of lymphoid progenitor cells. It is produced by monocytes, T cells, and NK cells.

interleukin 8 *abbr.*: IL-8; *other names*: monocyte-derived neutrophil chemotactic factor (MDNCF); T-cell chemotactic factor; neutrophil-activating protein 1 (NAP-1); lymphocyte-derived neutrophil-activating factor; protein 3-10C. An interleukin that acts as a chemotactic factor, attracting neutrophils, basophils, and T cells, but not monocytes. It is released from several cell types in response to inflammatory stimuli.

interleukin 9 *abbr.*: IL-9; *other names*: T-cell growth factor; p40 precursor. An interleukin that supports IL-2/IL-4-independent growth of helper T cells.

interleukin 10 *abbr.*: IL-10; *other names*: cytokine synthesis inhibitory factor (CSIF); cytokine glycoprotein. An interleukin that appears to be a suppressor factor for Th1 immune responses.

interleukin 11 *abbr.*: IL-11; *other name*: adipogenesis inhibitory factor (AGIF). An interleukin that acts as both cytokine and growth factor. It stimulates plasmacytoma proliferation, and the T-cell-dependent development of immunoglobulin-producing B cells.

interleukin 12 *abbr.*: IL-12; *other name*: cytotoxic lymphocyte maturation factor. An interleukin that can act as a growth factor for activated T and natural killer (NK) cells, enhance the lytic activity of NK/lymphokine-activated killer cells, and stimulate the production of interferon- γ by resting PMBC. It is a disulfide-linked heterodimer of 35 kDa (α) and 40 kDa (β) subunits. NK stimulatory factor (NKSF) is essentially a complex of cytokine and soluble receptor. Both subunits are glycoproteins; α has some similarity to **interleukin 6**; β has an immunoglobulin-like domain.

interleukin 13 *abbr.*: IL-13; an interleukin that inhibits inflammatory cytokine production. It synergizes with **interleukin 2** in regulating interferon- γ synthesis.

interleukin 15 *abbr.*: IL-15; an interleukin produced in various tissues that has biological functions similar to those of **interleukin 2**. Its receptor consists of an α subunit that activates JAK1 (*see* **JAK**), and a γ subunit of interleukin 2 receptor (IL-2R) that activates JAK3.

interleukin 16 *abbr.*: IL-16; an interleukin that binds T lymphocytes through CD4.

interleukin 1 β convertase EC 3.4.22.36; *other name*: interleukin-1 β converting enzyme (*abbr.*: ICE); a proteolytic enzyme that cleaves the interleukin-1 β precursor specifically at Asp¹¹⁶-|-Ala¹¹⁷ and Asp²⁷-|-Gly²⁸ in the precursor, producing the mature cytokine. It is a cysteine endopeptidase.

intermediary metabolism the chemical pathways by which molecules and structures found in living cells are synthesized from molecules that are taken into the cells, and subsequently broken down to molecules that are eliminated from the cells.

intermediate 1 occurring, or situated between two things in time, place, or order. **2** (*in chemistry or biochemistry*) any compound that takes part in a reaction, or sequence of reactions, occurring between the starting materials and the products. In metabolism, intermediates occur between the nutrients taken in and cellular material synthesized, or between cellular material and excretory products.

intermediate body a former name for **amboceptor**.

intermediate-density lipoprotein *abbr.*: IDL; one of the classes of lipoprotein found in blood plasma in many animals (data normally relate to humans). These lipoprotein particles have diameter 19.6–22.7 nm, solvent density for isolation (g mL^{-1}) 1.006–1.019, hydrated density (g mL^{-1}) 1.003. Their approximate composition (% by weight) is 8% unesterified cholesterol, 22% esterified cholesterol, 25% phospholipid, 30% triacylglycerol, 15% protein. Their apolipoprotein composition (% by weight total apolipoprotein) is 50–70% B-100, 5–10% C-I + C-II + C-III, 10–20% E-II + E-III + E-IV. They are formed in the plasma from very-low-density lipoproteins as a result of the action of **lipoprotein lipase**, and represent an intermediate stage in the conversion of very-low-density lipoproteins to low-density lipoproteins. *See also* **apolipoprotein** for individual apolipoproteins.

intermediate filament a distinct elongated structure, characteristically 10 nm in diameter, that occurs in the cytoplasm of higher eukaryotic cells. Intermediate filaments form a fibrous system, composed of chemically heterogeneous subunits and involved in mechanically integrating the various components of the cytoplasmic space. Intermediate filaments may be divided into five chemically distinct classes: **keratin** filaments of mammalian epithelial cells; **desmin** filaments found in cells of muscles of all types; **vimentin** filaments found in mesenchymal cells; neurofilaments of neurons; and glial filaments found in all types of glial cells. *Compare* **microfilament**, **microtubule**.

intermediate lobe or **intermediate part** or **pars intermedia** (**hypophyseos**) the part of the **pituitary gland** lying between the anterior and the posterior lobes. It is absent in adult humans but is present in fetal humans and in certain other species.

intermedin a former name for β -melanocyte-stimulating hormone (so-called because of its occurrence in the intermediate lobe of the pituitary gland). *See* **melanocyte-stimulating hormone**.

internal compensation the phenomenon of the existence of **internally compensated** molecular entities in general, or the property of such a molecular entity in a particular instance.

internal conversion *abbr.*: IC; a mode of radioactive decay of an excited atomic nucleus (formed by a nuclear transformation) in which, in a proportion of instances, excess energy released from the

nucleus is not radiated from the atom as a quantum of low-energy gamma radiation but is imparted to one of the inner orbital electrons, which is thereupon ejected as a **conversion electron**; the electron emission is homoenergetic. The filling of the vacant orbital in the resultant excited ion causes emission also of either an Auger electron or a quantum of the characteristic X-radiation of the daughter atom.

internal energy *symbol*: U or E ; a function of state that describes the sum of the kinetic and potential energy of a system. For closed systems, a change in internal energy, ΔU , usually results in a transfer of work or heat between the system and the surroundings. Thus $\Delta U = q + w$, where q is the heat gained by the system and w is the work done on the system.

internalin a surface protein of invasive forms of *Listeria monocytogenes*. It belongs to the invasins family, contains leucine-rich repeats, and binds to the epithelial transmembrane protein E-cadherin.

internal indicator any indicator substance used to follow a reaction, or other process, that is placed in the reaction mixture, or system.

internalize or **internalise** to render internal; especially to take a substance into a cell or organism. —**internalization** or **internalisation** *n*.

internally compensated describing any molecular entity that possesses equal numbers of structurally identical groups of opposite chirality. If no other chiral groups are present the overall entity is achiral and is designated by the prefix *meso*+.

internal ribosomal entry *abbr.*: IRE; the initiation of protein synthesis by certain viral and cellular mRNAs (e.g. those for cMyc, Apafl, and Xiap) by a mechanism that is independent of recognition of the 5' cap of the mRNA by the initiation factor eIF4E.

internal secretion a former name for **endocrine** (def. 2).

internal standard any standard used as a reference in an assay that is added to the samples and subjected to the whole of the procedures applied to them.

internal-standard method (of quench correction) or **internal standardization** a method of correcting for quenching in **liquid scintillation counting**. After the sample has been counted a measured small amount of a (nonquenching) standard preparation, of known activity, of the radionuclide in question is added to it and the sample is recounted. From the increment in the count rate the counting efficiency within the sample, and hence the degree of quenching, may be calculated. The method is simple and reliable and corrects adequately for all types of quenching but is more time-consuming than the **external-standard method** and has other disadvantages.

International Biological Standard any of the numerous internationally agreed standards of activity or potency of antisera, hormones, vitamins, antibiotics, and other biologicals. Each has been defined in terms of a mass of an appropriate standard preparation, prepared and stored under specified conditions.

International chemical identifier *abbr.*: INCHI; a unique, computer-readable identifier for a chemical compound. It consists of an alphanumeric string that describes the chemical structure.

International Practical Temperature Scale *abbr.*: IPTS; *see* **temperature**.

International System of Units the English translation of *Système International d'Unités*; *see* **SI**.

International Unit *abbr.*: IU (preferred) or i.u. or u; any unit of activity or potency of an antiserum, hormone, vitamin, antibiotic, or other biological defined in terms of the activity of an appropriate **International Biological Standard** or International Biological Reference Preparation. International Units are useful for quantifying a specific biological activity of a material before the chemical nature of the substance responsible for the activity has been fully characterized, or before pure preparations with reproducible activity are available.

Internet a protocol for allowing communication between computers, including those at distant sites. More loosely 'the internet' is used to refer to the worldwide network of such computers, including the providers of database services, discussion forums, and other communication media.

α -**internexin** *see* **peripherin**.

internuclear double resonance spectrometry *abbr.*: INDOR; a technique used in **nuclear magnetic resonance spectrometry** as an aid

to assignment of resonances. It involves monitoring a single frequency, f_1 (usually one corresponding to a single transition), while sweeping a perturbing (decoupling) frequency, f_2 , through a selected range of frequencies. Signals, negative or positive, will only appear in the INDOR spectrum when f_2 passes through a transition that has an energy level in common with the transition at f_2 , making it possible to determine otherwise inaccessible chemical shifts and coupling constants.

interoperability (*in computing*) the ability of different computers, networks, operating systems, and applications to communicate with one another seamlessly (i.e. without technological barriers).

interphase the state of a eukaryotic cell when not undergoing mitosis or meiosis. It covers the G₁, S, and G₂ phases of the **cell-division cycle**.

interpolate (*in mathematics*) to estimate a value of a function between data values already obtained or known either graphically or by calculation. *Compare* **extrapolate**. — **interpolation** *n*.

InterPro *see* **derived database**.

intersectin a protein partner of dynamin in the endocytosis machinery.

intersegment transfer a proposed mechanism for the transfer of a repressor of gene expression in a nonspecifically bound state to its target site. It involves the rapid and direct transfer of repressor from one segment of a DNA molecule to another as a consequence of the relative diffusion of these segments within the domain of the molecule.

interstice any minute space or crevice that intervenes between structures, e.g. between cells, organs, or tissues, or between atoms in a crystal lattice. — **interstitial** *adj*.

interstitial cell a connective tissue cell lying in the interstices between other cells in a tissue and serving to bind the tissue cells. Examples include the neuroglial cells, and the testosterone-producing Leydig cells lying between the seminiferous tubules in the testis of vertebrates.

interstitial cell-stimulating hormone *abbr.*: ICSH; *a former name for* **lutinizing hormone**.

interstitial collagenase EC 3.4.24.7; *other names*: vertebrate collagenase; matrix metalloproteinase 1; an enzyme that cleaves preferentially one bond in native collagen and catalyses the cleavage of the triple helix of collagen at about three-quarters of the length of the molecule from the N terminus, at Gly⁷⁷⁵-Ile⁷⁷⁶ in the α -1(I) chain. It cleaves synthetic substrates and α -macroglobulins at bonds where P1' is a hydrophobic residue. Zinc is a cofactor.

interstitial deletion the loss of DNA or part of a chromosome that occupies an interstitial (i.e. nonterminal) position.

interstitial fluid the portion of the **extracellular fluid**, consisting mainly of water, that occurs outside the blood vessels and the lymphatics. In a 70 kg man its volume is approximately 12 L and it represents approximately 17% of body mass. It has a higher content of sodium, chloride, and bicarbonate and a lower content of potassium, magnesium, sulfate, and phosphate than **intracellular fluid**.

intertrabecular space the space within cells lying between the elements of the **microtrabecular lattice**.

intervening sequence *an alternative name for* **intron**.

intimin an actin-polymerization-inducing protein produced by enteropathogenic and enterohemorrhagic strains of enteric bacteria. It is an outer membrane protein of *Escherichia coli*, necessary for attachment of the bacterium to epithelial cells.

intoxication 1 any metabolic process that converts a nontoxic **xenobiotic** to a toxic product. **2** poisoning, especially with ethanol, manifested in behavioural change of the subject.

intra+ *prefix* signifying within, on the inside, or during. *See also* **endo+**. *Compare* **inter+**.

intracellular within a cell or cells.

intracellular fluid *abbr.*: ICF; the portion of the total fluid content of a multicellular organism that occurs within the cells, especially as distinct from **extracellular fluid**. In a 70 kg man the volume of ICF is approximately 26.5 L, and it represents approximately 38% of body mass. It has a higher content of potassium, magnesium, sulfate, and phosphate, and a lower content of sodium, chloride, and bicarbonate than **interstitial fluid**.

intrachain (*of any interaction or linkage*) between different parts of a single chain of a biopolymer.

intra-dermal *abbr.* (*in medicine*): ID or i.d.; within the layers of the skin.

intragenic suppression *see* **suppression**.

intramolecular within the same molecule.

intramolecular chaperone a domain within a protein that mediates conformational change of that protein (i.e., exercises a **chaperone** function). **Trypsinogen**, e.g., contains such a domain.

intramuscular *abbr.* (*in medicine*): IM or i.m.; within a muscle or muscles; used especially of an injection.

intranet a computer network isolated from the Internet, often by means of a firewall, that offers typical Internet facilities to the local community (e.g. Web servers, email, bulletin boards).

intra-peritoneal *abbr.*: IP or i.p.; within the peritoneum; used especially of an injection, infusion, or aspiration.

intrapleural within the pleura or pleurae; used especially of an injection or aspiration.

intrathecal within the intradural or subarachnoid space; used especially of an injection or aspiration.

intravenous *abbr.* (*in medicine*): IV or i.v.; within a vein; used especially of an injection, infusion, transfusion, or aspiration.

intrinsic 1 of or pertaining to the essential nature of something; inherent. **2** (*in morphology*) peculiar to, or situated in a part. — **intrinsically** *adv*.

intrinsic activity *an alternative name for* **maximal agonist effect**.

intrinsically unstructured describing a protein or protein domain that lacks a folded structure but instead displays a highly flexible, random-coil-like conformation under physiological conditions. Examples include **calpastatin**, **casein**, and **tau**.

intrinsic association constant or **intrinsic binding constant** *see* **intrinsic constant**.

intrinsic birefringence the optical anisotropy of an individual molecule.

intrinsic constant any association, binding, or dissociation constant that describes the association, binding, or dissociation of a ligand to (or from) a particular site on a polyvalent molecule, when all the sites of this type are identical, present in the same molecule, and noninteracting.

intrinsic dissociation constant *see* **intrinsic constant**.

intrinsic efficacy *symbol: ϵ* ; an expression introduced by Furchgott that denotes the notional efficacy of a drug associated with a single receptor. It is given by $\epsilon = e/[R_0]$, where e is the **efficacy** and $[R_0]$ indicates the total concentration of active receptors of a certain type.

intrinsic factor *abbr.*: IF; a glycoprotein, secreted by the parietal cells of the gastric mucosa, that is necessary for the adequate absorption of dietary **cobalamins**. Intrinsic factor binds cobalamins in the intestinal lumen to form a complex that is subsequently bound by cubulin on the mucosa of the ileum. Cubulin is associated with LRP2 in the ileal mucosa and together they cause endocytosis of the IF-cobalamin complex. Cobalamin is bound to transcobalamin II in the portal blood. Congenital pernicious anemia is caused by absence of IF, a defect in cubulin, or deficiency in transcobalamin II of intrinsic factor.

intrinsic pathway (of blood coagulation) *see* **blood coagulation**.

intrinsic protein *less common term for* **integral (cell membrane) protein**.

intrinsic viscosity *symbol: η_{int}* ; the limiting value of the **specific viscosity**, η_{sp} , of a solution as the concentration of the solute tends to zero. The units are $\text{cm}^3 \text{g}^{-1}$. Its value depends on the specific volume of the (solvated) solute, V , and on a shape-dependent factor, ν , as follows: $\eta_{int} = \nu V$. The value of ν is 2.5 for a sphere and its value increases for solutes of other shapes. The name **limiting viscosity number** has been recommended for this attribute.

intron or **intervening sequence** any intragenic region of DNA in eukaryotes that is not expressed in a mature RNA molecule. Such regions occur between coding sequences (**exons**); this arrangement of introns alternating with exons constitutes a **transcription unit**. By customary usage, the term is extended to the corresponding regions of the **primary transcript** of RNA. In RNA, four general types of introns are distinguishable: (1) yeast nuclear tRNA; (2) group I introns; (3)

group II introns; and (4) nuclear mRNA precursor. Group I and II introns were first described for fungal mitochondrial genes; group I introns are characterized by a lack of conserved sequences at splicing junctions but have short conserved sequences internally, while group II introns have conserved sequences at the splicing junctions. The introns of different RNA types are spliced by different mechanisms (see **splicing**). It has been customary to describe introns as 'junk DNA', i.e. DNA for which no function can be found, but this concept must be modified. Many 'self-splicing introns' in the pre-rRNA of *Tetrahymena* double as mRNAs from which proteins are expressed that assist self-splicing and/or mediate intron translocation to new DNA sites. In the expression of a gene coding for small, stable RNAs that accumulate in the nucleolus, certainly of humans and mouse, it is the introns that give rise to RNA rather than the exons. Hence the terms intron and exon should simply signify RNA sequences that become physically separated during the process of RNA splicing. —**intronic adj.**

inulin a slightly soluble polysaccharide, of ≈6 kDa, found in members of the Compositae and Campanulaceae, in which it partially or completely replaces starch as a reserve carbohydrate. It is a linear glycan composed of about 35 (β2→1)-linked D-fructofuranose residues terminating in an (α1→2)-D-glucopyranosyl residue. Inulin is useful in the measurement of renal clearance, as inulin is neither reabsorbed nor secreted by the renal tubular cells. It is also useful in the measurement of extracellular fluid volume (**inulin space**), since it can pass through the blood capillary walls but is not taken up by cells.

inulobiose the disaccharide 2-O-β-D-fructofuranosyl-D-fructose.
inulosucrase EC 2.4.1.9; an enzyme that participates in inulin biosynthesis. See also **sucrase** (def. 3).

in utero *Latin* within the uterus.

in vacuo *Latin* in a vacuum.

invaginate 1 to infold, especially to form a sheathlike or saclike enclosure. **2** describing an organ or part that is folded back upon itself. —**invagination n.**

invariant chain or **CD74** or **Ii** a protein (31 kDa) of the endoplasmic reticulum (ER) lumen that binds newly formed class III MHC heterodimeric proteins so as to prevent binding of endogenous peptides to their groove. It acts as a chaperone for these molecules until they leave the Golgi apparatus and enter the endosome pathway. It is degraded proteolytically but leaves a fragment (called CLIP) bound within the groove. In acid vesicles, after leaving the Golgi apparatus, CLIP exchanges with peptides derived from exogenous antigens.

invariant residue any amino-acid residue that always occurs in equivalent positions in the polypeptide chains of homologous proteins from different species, or in genetic variants of the protein from a given species.

invasin 1 an alternative name for **hyaluronidase**. **2** any of a family of surface proteins of various intracellular bacterial pathogens by which the bacteria invade nonphagocytotic host cells (e.g. those of the gut epithelia). All contain leucine-rich repeats. See **internalin**.

invasive (*in pathology*) tending to penetrate into healthy tissue and grow within the host away from the site of entry or origin. It is used especially of a pathogenic organism, cell, or group of cells, e.g. cancer cells. —**invasiveness n.**

inverse agonist any ligand that by binding to receptors reduces the fraction of them in an active conformation, thereby having biological effects opposite to those produced by an **agonist** (as in **benzodiazepine inverse agonist**). This can occur if some of the receptors are in the active form even in the absence of a conventional agonist. Compare **partial inverse agonist**.

inverse PCR a variant form of **polymerase chain reaction** (PCR) in which DNA of unknown sequence but flanking a known sequence can be amplified. Digestion of the DNA with a restriction enzyme followed by ligation at low DNA concentrations favours the formation of closed circular molecules. PCR primers based on the known sequence are designed so that their 5' ends are adjacent on the two strands of the duplex. The PCR product is a linear DNA molecule containing known sequence at each end with unknown sequence between.

inverse-square law a law according to which the magnitude of a

physical quantity, e.g. the intensity of electromagnetic or other radiation, is proportional to the reciprocal of the square of the distance from the source of the property.

inversion 1 configurational inversion the process of changing the **configuration** about a chiral centre into that with the opposite configuration. See also **Walden inversion**. **2** the hydrolysis of sucrose to an equimolar mixture of glucose and fructose. It is so-called because of the accompanying reversal of direction of optical rotation by the solution. **3 chromosomal inversion** the excision of a chromosomal segment followed by its reinsertion at the same position after having been turned through 180°. **Paracentric inversions** are confined to one or other arms of the chromosome, whereas **pericentric inversions** span the centromere. Both types create changes in gene order, and sometimes cause disordered meiosis, genetic abnormalities, and reduced fertility.

inversion isomer an alternative name for **invertomer**.

invert 1 to turn or cause to turn inward, or upside down. **2** to reverse in direction, sequence, effect, etc. See also **inversion**.

invertase or **saccharase** EC 3.2.1.26; recommended name: β-fructofuranosidase; systematic name: β-D-fructofuranoside fructohydrolase. An enzyme from yeast and other sources that catalyses the **inversion** (def. 2) of sucrose. See also **saccharase**.

invertebrate 1 any animal lacking a vertebral column (backbone) and internal skeleton. **2** of, pertaining to, or designating any such animal.

inverted repeat or **indirect repeat** *abbr.*: IR; either of a pair of sequences in duplex DNA that exhibit two-fold rotational symmetry around a centre, the two sequences being complementary to each other. The sequence of the two repeats together is called a **palindrome**, e.g.

GGTACC
CCATGG.

The repeats need not be contiguous, e.g.

GGTNNACC
CCANNTGG.

Inverted repeats promote the formation of **cruciform** structures. Their function is unknown. However, they are found flanking transposable elements, which may indicate an associated role. See also **cruciform**, **dyad symmetry**, **hairpin**.

invertin an enzyme preparation from yeast. The major component is an α-glucosidase activity. See also **emulsin**.

invertomer or **inversion isomer** either of two **conformers** that interconvert by inversion at an atom possessing a nonbonding electron pair.

invert sugar an equimolar mixture of D-glucose and D-fructose formed by the hydrolysis, i.e. **inversion** (def. 2), of sucrose. It is sweeter than its parent disaccharide. See also **high-fructose corn syrup**.

invertin a family of conserved metalloproteases that contain an inverted zinc-binding site (i.e. His–Xaa–Xaa–Glu–His). Examples include insulinase and *E. coli* protease III.

in vitro *Latin* (of any biological process, reaction, or experiment) occurring or made to occur outside an organism, e.g. in extracts or cultures; literally it means 'in glass'. Compare **in vivo**.

in vitro packaging the assembly of head and tail proteins of bacteriophages with recombinant bacteriophage DNA to generate infectious phage particles.

in vitro transcription the generation of a sense or antisense RNA copy of a cDNA molecule usually carried in a plasmid or other vector. This is accomplished by using an RNA polymerase from T3, T7, or SP6 phage that initiates transcription from a cognate promoter situated upstream from the cloned DNA insert.

in vitro translation the generation of a polypeptide whose sequence is specified by mRNA added to extracts of reticulocytes or wheatgerm. Such extracts have all the components necessary for translation, including ribosomes, tRNAs, and amino acids. One or more of the amino acids can be radioactively labelled. This method is sometimes combined with *in vitro* transcription in the same reaction mixture.

in vivo *Latin* (of any biological process, reaction, or experiment) oc-

curing or made to occur within a living organism; literally it means 'in life'. Compare *in vitro*.

involucrin a protein of keratinocytes and other stratified squamous epithelia that first appears in the cell cytosol, but ultimately becomes cross-linked to membrane proteins by the action of transglutaminase.

involute **1** involved, intricate. **2** spiral, having whorls wound closely around the axis. **3** having edges that roll under or inwards. **4** to be subjected to a process involving the inward rolling of the surrounding tissue

iodo+ a variant form of **iodo+** (sometimes before a vowel).

iodate **1** the anion, IO_3^- , derived from iodic(v) acid. **2** any salt of iodic(v) acid.

iodide **1** the anion, I^- , of the element iodine. **2** any salt of hydriodic acid. **3** any compound containing an iodine atom in organic linkage.

iodide-chloride transporter or **Pendrin** a human integral membrane protein (780 amino acids) predicted to contain 11 transmembrane segments. It may be the iodide transporter on the colloid surface of thyroid follicle cells. More than 30 mutations in the gene lead to the Pendred syndrome of thyroid goitre with congenital deafness, or simple, isolated deafness.

iodide pump or **Na^+/I^- symporter** (*abbr.*: NIS) an integral membrane protein that cotransports Na^+ and I^- into the thyroid follicles. It is dependent on sodium/potassium ATPase activity, and is stimulated by thyroliberin. It contains 643 amino acids and is predicted to contain 12, 13, or 14 transmembrane segments. It is also present in salivary glands, gastric mucosa, choroid plexus, and mammary glands, and shares 30% sequence homology with the Na^+ /glucose transporter 1. Several mutations lead to congenital hypothyroidism as a result of a defect in entry of iodide into cells of thyroid follicle.

iodide trapping defect see **iodide pump**.

iodimetry a volumetric method of analysis applicable to substances with a redox potential appreciably lower than that of the iodine-iodide system ($E^\circ = +0.535 \text{ V}$ at 25°C). Such substances are oxidized by iodine and may therefore be titrated in acid solution with a standard solution of iodine. Compare **iodometry**. —**iodimetric** *adj.*; **iodimetrically** *adv.*

iodinatable capable of being converted into an iodo derivative. The term may be used of an organic compound or a particular part of one, such as a residue in a peptide.

iodinate **1** to treat or react (a substance) with iodine. **2** to introduce one or more iodo groups into (an organic compound), whether by addition or substitution. —**iodination** *n.*

iodine **1** *symbol*: I; a nonmetallic element of group 17 of the IUPAC periodic table and one of the halogens; proton number 53; it exists naturally as a single stable nuclide, **iodine-127**, of relative atomic mass 126.904. It is widely distributed in nature, although never found as the free element, and is an essential dietary element. Numerous (about 29 unstable and seven metastable) artificial radioactive nuclides are known. Of these, the most widely used in biochemistry and molecular biology are **iodine-125** and **iodine-131**. **2** *symbol*: I_2 ; the common name for the substance correctly known as diiodine, a bluish-black solid that sublimates at room temperature into a violet-coloured irritating vapour. An ethanolic solution is useful as a mild topical antiseptic.

iodine-125 the artificial radioactive nuclide $^{125}_{53}\text{I}$. It decays to the stable nuclide tellurium-125 by capture to the nucleus of an orbital electron from the K (i.e. innermost) shell, emitting low-energy gamma radiation (35.5 keV, 7% emitted and 93% internally converted) and characteristic tellurium K X-radiation (27–32 keV, 140%), but no beta radiation. It has a half-life of 59.6 days.

iodine-127 the stable nuclide $^{127}_{53}\text{I}$. Its relative abundance in natural iodine is 100 atom percent.

iodine-131 the artificial radioactive nuclide $^{131}_{53}\text{I}$. It decays to the stable nuclide xenon-131, emitting a moderate-energy electron or beta particle of various energies (0.25–0.81 MeV max., mainly 0.61 MeV max.) plus gamma radiation of various energies (0.08–0.72 MeV, mainly 0.36 MeV), 1.3% of nuclides decaying via the metastable nuclide xenon-131m. It has a half-life of 8.04 days.

iodine-labelling a widely used procedure for labelling a compound

or material by introducing into it, directly or indirectly, one or more atoms per molecule of iodine, especially radioactive isotopes (i.e. radioiodine). See also **radioiodinate**.

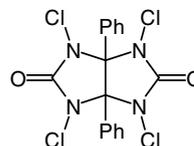

iodine number or **iodine value** a measure of the degree of unsaturation of a fat or fatty acid, defined as the number of grams of iodine capable of reacting with 100 g of the sample. It is usually determined indirectly by measuring the amount of an iodine-containing reagent, e.g. iodine monobromide, that remains after excess has been added and reaction is complete. The iodine number of saturated fatty acids is zero, that of oleic acid is 90, of linoleic acid 181, and of linolenic acid 274.

iodo of, relating to, or describing a compound that contains an iodine atom in organic linkage.

iodo+ or (sometimes before a vowel) **iod+** *comb. form* denoting **1** an iodine atom in organic linkage. **2** violet-coloured. See also **iodo**.

iodoacetamide $\text{I}-\text{CH}_2-\text{CONH}_2$; a compound that acts as an inhibitor of an enzyme containing $-\text{SH}$ groups, $\text{Enz}-\text{SH}$, by reacting irreversibly to give $\text{Enz}-\text{S}-\text{CH}_2-\text{CONH}_2$, with elimination of HI .

Iodo-Gen a proprietary name for 1,3,4,6-tetrachloro-3 α ,6 α -diphenylglycouril; a solid-phase reagent that oxidizes low concentrations of inorganic iodide to iodine and hence is useful for the rapid and efficient labelling of proteins with radioactive iodine. Being very stable and virtually insoluble in water, it can be used in the form of a prior coating on the walls of a reaction vessel containing aqueous solutions of iodide ion and protein.

iodogorgoic acid a former name for 3,5-diiodotyrosine.

iodometry a volumetric method of analysis applicable to substances with a redox potential appreciably higher than that of the iodine-iodide system ($E^\circ = +0.535 \text{ V}$ at 25°C). Such substances are reduced by iodide, which is added in excess to acidified solutions and the liberated iodine titrated with a standard solution of thiosulfate. Compare **iodimetry**. —**iodometric** *adj.*; **iodometrically** *adv.*

iodopsin any of three light-sensitive visual pigments in the cone cells of the retinas of vertebrates, other than freshwater and migratory fishes, and some amphibians. They consist of different cone-type opsins combined (as Schiff's bases) with 11-*cis*-retinal. Each individual cone cell contains one of the three pigments, which have absorption maxima at ~430 nm, ~540 nm, and ~575 nm. The iodopsins were once thought to be a single pigment, termed visual purple or visual violet. See also **cyanopsin**, **retinal**.

iodotyrosine deiodinase an NADPH-dependent flavoprotein enzyme that deiodinates monoiodotyrosine and diiodotyrosine derived from proteolytic degradation of thyroglobulin within lysosomes of thyroid follicle cells. The released iodide (I^-) is recycled by the thyroperoxidase of those cells. Enzyme deficiency leads to excessive loss of the iodotyrosines and to congenital goitre and hypothyroidism.

ion any atom or other molecular entity that has acquired an electric charge by loss or gain of one or more electrons. An anion is negatively charged, and a cation is positively charged.

ion atmosphere the region surrounding a charged molecular entity in which there is a statistical preference for ions of opposite charge.

ion chamber another name for **ionization chamber**.

ion channel any channel in cell membranes that allows the passage of specific inorganic ions through the membrane. Ion channels may be **ligand-gated**, **voltage-gated**, or **mechanically gated channels**. For ligand-gated channels, the ligand may be extracellular such as a neurotransmitter (**transmitter-gated channel**), or intracellular such as an ion (**ion-gated channel**), or a nucleotide. Ion channels are common direct or indirect targets for the action of drugs, which may either potentiate or inhibit channel opening.

ion exchange the process in which ions of like charge, which may

be the same or different chemically, are exchanged between two phases, such as two solutions separated by a semipermeable membrane or a solution and an insoluble material, e.g. a resin.

ion-exchange cellulose *abbr.*: IEC; any derivatized cellulose containing cationic or anionic substituents used in **ion exchange**, especially for the separation of charged biopolymers.

ion-exchange chromatography any form of chromatography that depends on the process of **ion exchange** to effect the separation.

ion-exchange polymer an insoluble polymer that has ionic groups and is able to exchange counterions with the ionic components of a solution. Cation exchangers carry anionic groups such as sulfonate or carboxyl, whereas anion exchangers carry cationic groups such as primary or quaternary ammonium groups. An ion-exchange polymer in ionized form may also be referred to as a **polyanion** or a **polycation**.

ion exchanger any **anion exchanger** or **cation exchanger**.

ion-exchange resin a former term (now discouraged) for **ion-exchange polymer**.

ion-exclusion chromatography a chromatographic technique by which strong electrolytes can be separated from nonelectrolytes and weak electrolytes by passage of the mixture through an ion-exchange resin in a buffer of ionic strength and pH that can be varied in the course of the separation. At low salt concentrations particularly, ionic repulsive forces tend to exclude from the resin those ions that have the same charge as the functional groups on the resin so that these ions, together with an equivalent number of counterions, pass rapidly through the column while nonelectrolytes and weak electrolytes enter the resin and thus pass more slowly through the column at a rate determined in part by the pK of their ionizable groups.

ion-gated channel *see* **ion channel**.

ionic 1 of, pertaining to, existing as, or characterized by **ions**. **2** using or operated by ions.

ionic atmosphere the cloud of ions of one charge type that tend to accumulate by interionic attraction around an ion of the other charge type in a solution of an electrolyte. The cloud is symmetrical about the charge on the central ion unless the solution is subjected to a shearing force conducive to flow or is exposed to an applied electric field. In the latter event the central ion and its surrounding counterions migrate in opposite directions, the resultant asymmetric disposition of the ionic atmosphere effecting retardation of the central ion in a concentration-dependent manner.

ionic bond any bond formed by attraction between a positively and a negatively charged group on different parts of the same molecule or on different molecules.

ionic conduction the passage of electricity due to the movement of ions.

ionic detergent any **anionic detergent** or **cationic detergent**. *Compare* **nonionic detergent**.

ionic double layer the region surrounding a charged molecular entity together with the layer of **counterions** that surrounds it.

ionic mobility a measure of the velocity at which an ion moves through a liquid under the influence of an applied electric potential.

ionic product *see* **ion product**.

ionic strength *symbol*: I or I_m (molality basis) or I_c (concentration basis); a physical quantity equal to half the summation over all ions in a solution of the concentration of each ion multiplied by the square of its charge. Hence,

$$I_m = 0.5(\sum m_i z_i^2)$$

and

$$I_c = 0.5(\sum c_i z_i^2),$$

where m_i and c_i are the molal and molar concentrations of the i th ion, respectively, and z_i is its charge.

ionizable group or **ionisable group** any uncharged group in a molecular entity that is capable of dissociating by yielding an ion (usually an H^+ ion) or an electron and itself becoming oppositely charged, or of associating with an ion (usually an H^+ ion) and itself assuming the ion's charge. The extent to which an ionizable group becomes an ionizing group depends on the constitution of the molecular entity and upon the environment.

ionization or **ionisation** any of the processes by which one or more ions are generated. It may occur, e.g., by loss or gain of a hydron by a solute in response to changes in pH, or by the loss of an electron from a neutral chemical species by unimolecular heterolysis of such a species into two or more ions. Further, a gas may become ionized by the passage through it of fast charged particles or electromagnetic radiation.

ionization chamber or **ionisation chamber** or **ion chamber** a chamber containing a gas and two electrodes between which an electric potential difference is maintained. It is used to detect ionizing particles or electromagnetic radiation by virtue of the current that flows following ionization of the gas.

ionization constant or **ionisation constant** the **dissociation constant** for a reversible reaction in which the products are ionic.

ionization energy or **ionisation energy** *symbol*: E_i ; the minimum energy (enthalpy) required to remove an electron from an isolated molecular entity (in its vibrational ground state) in the gaseous phase. It was formerly, and misleadingly, termed ionization potential.

ionization potential or **ionisation potential** a former term for **ionization energy**.

ionize or **ionise** to convert, or to become converted, wholly or in part, into ions; to cause **ionization** of (something). —**ionizable** *adj.*

ionizing particle or **ionising particle** any charged particle of sufficient energy to enable it to dislodge an orbital electron from an atom or other molecular entity. *See* **ionizing radiation**.

ionizing power or **ionising power** or (*sometimes*) **polarity** a qualitative term used to denote the tendency of a particular solvent to promote ionization of an uncharged solute.

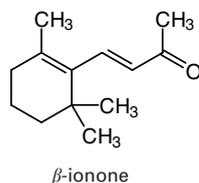

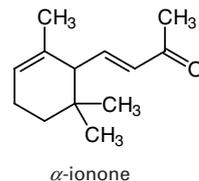

ionizing radiation or **ionising radiation** any radiation, corpuscular or electromagnetic, that is capable of causing **ionization** (directly or indirectly) of matter through which it passes. For ionization to occur, the kinetic or photon energy, respectively, must be greater than the **ionization energy** of the irradiated substance. Ultraviolet radiation, X-radiation, alpha particles, and high-energy electrons (including beta particles) are more effective than gamma radiation or neutrons. It is commonly known simply as radiation.

ionogen 1 any compound that can dissociate into ions in a suitable environment; an electrolyte. **2** any atom or group that is capable of becoming ionized chemically. —**ionogenic** *adj.*

ionography an alternative name for **zone electrophoresis**.

ionomycin a nonfluorescent antibiotic ionophore derived from *Streptomyces conglobatus*. It is highly specific for divalent cations and exhibits greater selectivity for Ca^{2+} over Mg^{2+} than **A23187** (calcimycin). It complexes with Ca^{2+} between pH 7 and 9.5 with intense UV absorption, and thus may be used as a carrier of Ca^{2+} and for measurement of cytoplasmic Ca^{2+} concentration.

ionone either of two terpene compounds, α -ionone and β -ionone, found in a number of plants. β -Ionone is an intermediate in the synthesis of vitamin A; its odour is reminiscent of cedarwood or, in dilute alcohol solution, of violets.

ionophore or **ionophorous agent** any member of a varied group of both natural and synthetic substances, cyclic or linear and of greatly differing relative molecular masses, that are capable of binding metal ions in solution and transporting them across lipid barriers in natural or artificial membranes. They may be classed as **cage carriers**, when the ionophore surrounds the metal ion during transport, or as **channel carriers**, when the ionophore forms an ion-conducting pore in the membrane. —**ionophorous** or **ionophoric** *adj.*

ionophoresis electrophoresis, especially of relatively small ions. *See also iontophoresis.*

ionotropic describing a type of receptor that mediates its effects by regulating ion channels, in distinction from receptors that act by regulating enzymes such as adenylate cyclase or inositide-specific phospholipase C. *Compare metabotropic.* *See also excitatory amino-acid receptor.*

ion pair a pair of oppositely charged ions held together by coulombic attraction. *See also ionic bond.*

ion product or (*sometimes*) **ionic product** *symbol:* K_i ; a measure of the tendency of an amphiprotic solvent, XH, to take up or to lose a hydron in the reaction:

In such a reaction, $K_i = a_{\text{XH}_2^+} \times a_{\text{X}^-}$ where $a_{\text{XH}_2^+}$ and a_{X^-} are the activities of XH_2^+ and X^- , respectively. The ion product of water, K_w , is given by

$$K_w = a_{\text{H}_3\text{O}^+} \times a_{\text{OH}^-}; K_w \approx 1 \times 10^{-14} \text{ mol}^2 \text{ dm}^{-6} \text{ at } 25^\circ\text{C}.$$

It has a large positive temperature coefficient.

ion pump a **transporter** that actively transports ions across a membrane against an **electrochemical potential**. *See active transport.*

ion-selective electrode or **ion-selective microelectrode** any electrode (or microelectrode) whose potential responds in a reproducible manner to changes in the concentration (strictly, in the activity) of a specific kind of ion in the solution in which the electrode is immersed and that is insensitive, or essentially so, to changes in the concentrations (strictly, in the activities) of all other kinds of ion in the solution. The electrode has at its surface a thin membrane of electrically conducting material, separating the internal and external solutions, across which an electric potential difference develops. The membrane consists of or contains an electroactive material responsive to the ions to be determined.

iontophoresis 1 the introduction of drugs and other substances through plasma membranes of cultured cells by the transfer of ions brought about by the application of a small electrical potential through electrodes placed on the membrane. **2** a *less common word* for **ionophoresis**.

iota *symbol:* ι (lower case) or I (upper case); the ninth letter of the Greek alphabet. For uses *see Appendix A.*

iotoxin any of a family of peptidic pore-forming toxins of 150–800 amino acid residues, permitting the passage of small molecules across membranes. Iotoxins are produced by *Clostridium perfringens*. They belong to the TC 1.C.42 family.

IP 1 or **i.p.** *abbr.* for intraperitoneal or intraperitoneally. **2** *abbr.* for Internet protocol. *See protocol.*

IP₂ *abbr.* for 1D-myo-inositol 3,4-bisphosphate.

IP₃ *abbr.* for 1D-myo-inositol 1,3,4- (or 1,4,5-) trisphosphate.

IP₄ *abbr.* for 1D-myo-inositol 1,3,4,5-tetrakisphosphate.

IP address a unique software address for an Internet computer. Although actually a binary number it is usually represented in dotted decimal notation, e.g. '130.88.203.71'. Associated with this is a 'named' version (e.g. www.oup.co.uk corresponding to the dotted decimal address above at the time of writing). The conventions for named addresses include a two-letter abbreviation for a country (e.g. uk for the United Kingdom, ca for Canada, in for India, de for Germany) except for addresses in the USA: because IP is American, the default country is the USA. The 'co' in the example above stands for 'commercial'; other possibilities include ac (academic), gov (government), or org (organization). In the USA the corresponding abbreviations are all of three letters (com for commercial, edu for educational, mil for military; org and gov are also used in the USA). Some countries (e.g. Germany) do not usually have this field.

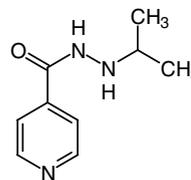

ipecacuanha or **ipecac** the dried root of the South American shrub, *Cephaelis ipecacuanha*; it contains the alkaloids **cephaeline** and **emetine**. Ipecacuanha preparations are used as emetics and expectorants.

IPP *abbr.* for Δ^3 -isopentenyl pyrophosphate. This compound is now preferably called isopentenyl diphosphate (*abbr.:* IDP).

iPr *symbol* for the isopropyl group, $(\text{CH}_3)_2\text{CH}-$ (alternative to Pr¹).

IP₃ receptor a receptor/ Ca^{2+} channel of the endoplasmic reticulum (ER). On binding of inositol 1,4,5-trisphosphate (IP₃), released by the action of phospholipase C from phosphatidyl inositol 3,4-bisphosphate on the inner leaflet of the plasma membrane, the channel opens to release Ca^{2+} ions from the ER lumen into the cytosol. The receptor's subunits each contain six transmembrane segments. Homer1 mediates the effect of ligand binding to metabotropic glutamate receptors on the IP₃ receptor.

iproniazid 1-isonicotinoyl-2-isopropylhydrazine; a derivative of **isoniazid** that is a **monoamine oxidase** inhibitor.

Ips *symbol* for the pipsyl group.

IPTG *abbr.* for isopropyl β -D-thiogalactoside; a gratuitous inducer of the *lac* operon in *E. coli*.

IPTS *abbr.* for International Practical Temperature Scale.

Ir *symbol* for iridium.

IR 1 or **i.r.** *abbr.* for infrared (radiation). **2** *abbr.* for inverted repeat. **3** *abbr.* for information retrieval.

IRAK *abbr.* for IL-1 receptor-associated kinase; a human cytosolic serine/threonine protein kinase of 752 amino acids that binds to liganded interleukin 1 (IL-1) receptor. Its function is unknown.

IRE *abbr.* for iron response element.

I₁, I₂ receptors *see imidazoline receptor.*

IREG *abbr.* for iron-regulated transporter. *See ferroportin.*

IRES *abbr.* for internal ribosome entry site; a sequence found immediately upstream from a cistron in polycistronic mRNA – such as produced by transcription of encephalomyocarditis and other viral genomes – that allows ribosomes to initiate translation from a secondary site within the transcript rather than assembling at the 5' cap, as is usual with the translation of eukaryotic mRNAs.

IRG *abbr.* for immunoreactive glucagon.

Ir genes the genes, including those within the **MHC**, that together determine the overall level of immune response to a given **antigen**.

IRMA *abbr.* for immunoradiometric assay.

iron *symbol:* Fe; a metallic element of group 8 of the IUPAC **periodic table**; proton number 26; natural iron has a relative atomic mass of 55.847 and is a mixture of stable nuclides of nucleon numbers 54 (5.8 atom per cent), 56 (91.7 atom per cent), 57 (2.2 atom per cent), and 58 (0.3 atom per cent). About 12 artificial radioactive nuclides are known; of these, **iron-59** is the one most widely used in biochemistry and molecular biology. Iron is a **transition element** and hence forms ionic salts and numerous complexes in the oxidation states +2, i.e. iron(II) (ferrous iron), or +3, i.e. iron(III) (ferric iron). Iron is one of the most important elements in biology; it is essential in substantial quantities to all cellular organisms from bacteria to mammals, particularly for the synthesis of hemoproteins such as **cytochromes**, **hemoglobins** and related proteins, **myoglobin**, **catalase**, and some **peroxidases**. Important iron-transport proteins include **ferritin** and **transferrin**; iron is taken up into mammalian cells, bound to transferrin, by the **transferrin receptor**. There is no physiological excretory mechanism for iron, but it is lost from females during menstruation.

iron-59 the artificial radioactive nuclide $^{59}_{26}\text{Fe}$. It decays to the stable nuclide cobalt-59 with emission of a beta particle (i.e. an electron) in two moderate-energy ranges (0.27 MeV max., 48%, and 0.48

MeV max., 51%) plus gamma radiation of various energies (mainly 1.10 MeV, 56%, and 1.29 MeV, 43%). It has a half-life of 44.5 days.

iron hydrogenase *abbr.*: [Fe]- or [FeFe]-hydrogenase; any of a family of hydrogenases (EC 1.12.) present in some bacteria, anaerobic fungi, ciliates, flagellates, and green algae, within the cytosol, the cell membrane, or in hydrogenosomes. Two nonhomologous classes are recognized: (1) hydrogenases containing an H cluster comprising a dimer of iron atoms linked to a [4Fe-4S] cluster; and (2) hydrogenases containing a single iron atom.

iron-molybdenum cofactor *abbr.*: FeMo-co; *see* *nif*, nitrogenase.

iron overload a condition of humans in which iron is taken up in excess over a prolonged period. As there is no excretory mechanism for iron, it accumulates in Kupffer cells in the liver as **hemosiderin**, a form of **ferritin** complexed with other proteins and iron. The condition is known as **hemosiderosis**. It also occurs as a result of repeated blood transfusions, e.g. in treatment for the hemoglobinopathies. A form of the condition is referred to as **Bantu siderosis**, being very prevalent in the Bantu people of southern Africa; it was formerly thought to be always caused by use of cast-iron vessels for cooking, but in some families a hereditary susceptibility has been found.

iron-regulated transporter *abbr.*: IREG; *an alternative name for ferroportin*.

iron regulatory protein *abbr.*: IRP; a cytoplasmic protein that binds an iron-response element present in mRNAs for proteins involved in iron metabolism.

iron response element or iron regulatory element *abbr.*: IRE; a base sequence in eukaryotic 5' or 3' untranslated regions of mRNAs, that either blocks translation or enhances stability of the mRNA for proteins involved in iron metabolism (e.g. ferritin, transferrin receptor). The IRE is modulated by an iron regulatory protein that binds to it.

iron-sulfur cluster a unit comprising two or more iron atoms and bridging sulfide ligands in an **iron-sulfur protein**. The recommended designation of a cluster consists of the iron and sulfide content, in square brackets, for example [2Fe-2S], [3Fe-4S]. The possible oxidation levels are indicated by the net charge excluding the ligands, for example: a [4Fe-4S]²⁺; [4Fe-4S]¹⁺ (or [4Fe-4S]^{2+;1+}) cluster.

iron-sulfur protein *abbr.*: Fe-S protein; any member of a group of proteins to which iron is bound via sulfur-containing ligands (excluding hemoproteins containing iron linked only through axial sulfur ligands). Iron-sulfur proteins are characterized by the possession of non-heme bound iron, as well as one or more of the following: (1) acid-labile sulfur; (2) absorption bands between 300 and 600 nm; (3) the capability of transferring electrons at low redox potential; and (4) paramagnetism in one or more oxidation states. They may be classified as **simple** if they contain one or more Fe-S clusters only (*see* **ferredoxin**, **rubredoxin**), and **complex** where additional active groups, such as flavin, heme, or another metal, are present.

IRP *abbr.* for iron regulatory protein.

irradiate to subject to or treat with electromagnetic radiation or beams of particles. —**irradiation** *n*.

irreversible competitive antagonist (*in pharmacology*) an antagonist for which the dissociation rate is so low that antagonist molecules cannot be replaced by increasing the concentration of an agonist for the same receptor.

irreversible process any process occurring in an isothermal system without change of internal energy but with an increase in entropy.

IRS *abbr.* for insulin receptor substrate.

IS *abbr.* for insertion sequence.

ischemia or (*esp. Brit.*) **ischaemia** a disorder of function caused by insufficient blood flow. Resumption of the blood supply may lead to **ischemia-reperfusion injury** due to the formation of reactive oxygen species.

islet any small group of cells that is structurally distinct from the surrounding tissue, especially the **islets of Langerhans**.

islet-1 *abbr.*: ISL-1; *other name*: insulin-related protein; a transcription factor that is expressed during vertebrate embryogenesis in several neuronal and other cell types (including pancreatic B cells). It contains a homology region of 50–60 amino acids, called LIM, that is also present in Lin-II ISL-1, and Mec-3 of *Caenorhabditis elegans*.

It forms a double zinc finger and may be involved in protein, rather than DNA, binding.

islet-activating protein *abbr.*: IAP; *a former name for pertussis toxin* (so-called because it stimulates release of insulin from the islets of Langerhans).

islets of Langerhans or (*sometimes*) **islands of Langerhans** or **pancreatic islets** the numerous small, spherical or oval, highly vascular clusters of endocrine cells that lie scattered throughout the acinar (i.e. exocrine) tissue of the pancreas of gnathostome (i.e. jaw-bearing) vertebrates and are readily distinguishable microscopically from it. The normal adult human pancreas contains about 2 million islets, which together comprise under 2% of its total volume. Islets commonly consist of three main types of cells, all granule-containing: the glucagon-secreting **A cells**; the insulin-secreting **B cells**; and the somatostatin-secreting **D cells**. Some other types of hormone-secreting cells may be present also. [After Paul Langerhans (1847–88), German physician and anatomist, who first described such clusters of cells (1869).]

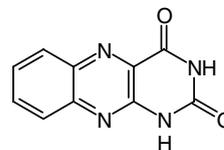

iso+ or (*sometimes before a vowel*) **is+** *comb. form* 1 equal, the same, uniform, homogeneous. *Compare* **allo+** (def. 1), **homo+** (def. 1), **hetero+** (def. 1), **xeno+** (def. 1). **2** (*in immunology and genetics*) **a** in or of some individual or ones that are genetically identical (e.g. **isogenic**). **b** in or of another, genetically differing individual of the same species (e.g. **isoantigen**); **allo+** (def. 2) is now usually preferred. **c** in or of all normal individuals of the same species (e.g. **isotypic**). *Compare* **allo+** (def. 2), **hetero+** (def. 2), **homo+** (def. 2), **xeno+** (def. 2). **3** (*in chemical nomenclature*) **a** signifying isomer of (formerly 'iso' was italicized and often hyphenated). **b** *symbol*: i (as a prefix or superscript); signifying the isomer of a straight-chain alkane or alkane derivative that differs only in having a terminal (CH₃)₂CH- group (leucine and isoleucine are exceptions). *Compare* **allo+** (def. 3), **nor+** (def. 1). **4** (*in names of certain classes of macromolecules*) signifying irrespective of location or origin, one of two or more structural variants with the same specificity of activity or action (e.g. **isoacceptor tRNA**, **isohormone**; *see also* **isoenzyme**).

ISO *abbr.* for International Standards Organization.

isoacceptor tRNA or isoaccepting tRNA any transfer RNA species obtainable from a given organism that can be acylated by the same amino acid; they may differ in their anticodons.

isoagglutinin *other names*: isohemagglutinin; isoantibody; a naturally occurring IgM antibody that is specific for one of the ABO blood group antigens on human erythrocytes. Type O blood has antibodies to A and B antigens; type A has antibodies to B antigen; type B has antibodies to A antigens; and type AB has neither anti-A nor anti-B antibodies. The presence of isoagglutinins in blood explains the disastrous effect of incompatible blood transfusions.

isoalloxazine *benzo[g]pteridine-2,4(1H,3H)dione*; the hypothetical tricyclic parent compound of any N¹⁰-substituted alloxazine in riboflavin, flavin mononucleotide, or flavin-adenine dinucleotide.

isoamylase EC 3.2.1.68; *other name*: debranching enzyme; an enzyme that catalyses the hydrolysis of 1,6- α -D-glucosidic branch linkages in glycogen, amylopectin, and their β -limit dextrins. It does not attack pullulan, and is limited in action on α -limit dextrins.

isoantibody any antibody formed in one individual in response to an antigen derived from another individual of the same species. *See also* **isoagglutinin**.

isoantigen any antigen occurring in an individual that is capable of eliciting an immune response in genetically different individuals of the same species but not in the individual itself.

isoasparagine *the trivial name for the α -amide of aspartic acid*, aspartic 1-amide; β -aminosuccinamic acid; 3-amino-3-carbamoyl-

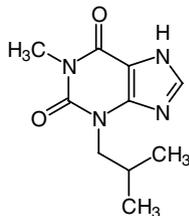

propanoic acid; $\text{H}_2\text{N}-\text{CO}-\text{CH}(\text{NH}_2)-\text{CH}_2-\text{COOH}$; a chiral α -aminoacylamide. L-Isoasparagine (*symbol*: Asp-NH₂) can occur as an N-terminal amidated residue of proteins. *Compare* asparagine.

isoasparaginylyl the acyl group, $\text{H}_2\text{N}-\text{CO}-\text{CH}(\text{NH}_2)-\text{CH}_2-\text{CO}-$, derived from **isoasparagine**. *Compare* asparaginylyl.

isoaspartyl the former name for **β -aspartyl**.

isobar 1 any of two or more nuclides having the same mass number (nucleon number) but different atomic numbers (proton numbers) and hence of differing chemical properties. *See also* heterotope. 2 any curve or equation relating quantities measured at the same pressure; any line joining points on a graph or map that have equal pressures. —**isobaric** *adj.*

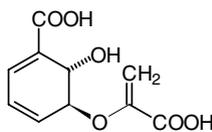

isobutylmethylxanthine *abbr.*: IBMX; 3-isobutyl-1-methylxanthine; an inhibitor of **cyclic AMP phosphodiesterase**; it raises cyclic AMP levels in cells and tissues.

isocaloric (*of foodstuffs*) having the same **calorific value**.

isochore a stretch of DNA that is over 300 kb long and has a relatively homogeneous GC composition.

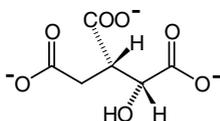

isochorismate 5-[(1-carboxylatoethenyl)oxy]-6-hydroxy-1,3-cyclohexadiene-1-carboxylate; the dianion of isochorismic acid; an isomer of **chorismate** and an important precursor to some compounds in the **shikimate pathway**.

isochorismic acid

isochromosome any chromosome having homologous, genetically identical arms. It results from abnormal splitting of a chromosome at the centrosome during mitosis so that one arm is lost and the other becomes duplicated.

isocitrate 1 any of the anionic forms of isocitric acid, 1-hydroxy-1,2,3-propanetricarboxylic acid. (1*R*,2*S*)-1-hydroxypropane-1,2,3-tricarboxylate (*also termed* (2*R*,3*S*)-isocitrate or *threo*-D₃-isocitrate) is an important intermediate in the **tricarboxylic-acid cycle** and the **glyoxylate cycle**. 2 any mixture of free isocitric acid and its ionized forms. 3 any (partial or full) salt or ester of isocitric acid.

(1*R*,2*S*)-1-hydroxypropane-1,2,3-tricarboxylate

isocitrate dehydrogenase 1 **isocitrate dehydrogenase** (NAD⁺) EC 1.1.1.41; *other names*: isocitric dehydrogenase; β -ketoglutaric-isocitric carboxylase; an enzyme that catalyses the oxidation of isocitrate to 2-oxoglutarate and CO₂, with reduction of NAD⁺ to NADH. The isomer of isocitrate involved is (1*R*,2*S*)-1-hydroxypropane-1,2,3-tricarboxylate. In mammalian tissues, this enzyme is localized exclusively in the mitochondria. 2 **Isocitrate dehydrogenase** (NADP⁺) (EC 1.1.1.42); an enzyme that is localized in both mitochondria and cytosol.

[isocitrate dehydrogenase (NADP⁺)] kinase EC 2.7.1.116; *other names*: isocitrate dehydrogenase kinase/phosphatase (*abbr.*: IDH kinase/phosphatase); an enzyme that catalyses the phosphorylation by ATP of isocitrate dehydrogenase (NADP⁺) with formation of ADP. The phosphorylated protein is inactive. In *Escherichia coli* a bifunctional enzyme contains this and isocitrate dehydrogenase kinase/phosphatase (EC 3.1.3.-) activities.

isocitrate lyase EC 4.1.3.1; *systematic name*: isocitrate glyoxalate-lyase; an enzyme, present in the glyoxysomes of seeds, that converts (1*R*,2*S*)-1-hydroxypropane-1,2,3-tricarboxylate (the isomer of isocitrate involved) to succinate and glyoxylate. *See* **glyoxylate cycle**.

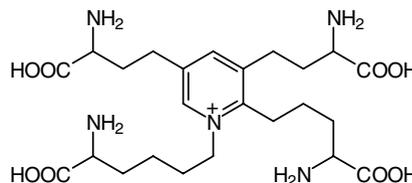

isocratic (*in chemistry*) describing any chromatographic procedure or separation in which the composition of the eluent is maintained constant. *Compare* **gradient elution**.

isocyanate any organic compound containing the univalent group $-\text{N}=\text{C}=\text{O}$. *Compare* **cyanate**, **isothiocyanate**.

isocyclic *see* **homocyclic** (def. 1).

isodalt a type of very-high-resolution two-dimensional electrophoresis system for the analysis of small (1–2 mg) samples of complex mixtures of proteins. It employs isoelectric focusing in cylindrical gels in the first dimension, followed by slab-gel electrophoresis in the presence of sodium dodecyl sulfate in the second dimension. Such systems are considered to be capable of resolving mixtures containing 10⁴ or more individual proteins within the range 10–200 kDa.

isodesmosine the 2-(4-amino-4-carboxybutyl)-1-(5-amino-5-carboxypentyl)-3,5-bis(3-amino-3-carboxypropyl)pyridinium ion; a tetra(α -amino acid) isolated from hydrolysates of the fibrous protein elastin. *See* **desmosine**.

isodiametric 1 (*of cells*) having similar diameters in all planes. 2 (*of a crystal*) having three equal axes.

isodynamic (*in physics*) having equal force or strength.

isoelectric 1 having the same electrical potential; containing or indicating no potential difference. 2 (*of particles or molecular entities*) having no net electric charge.

isoelectric focusing or **electrofocusing** *abbr.*: IEF; a technique in which solutes of different isoelectric points are caused to form stationary bands in an electric field, which is superimposed on a (stable) pH gradient, the pH increasing from the anode to the cathode. In practice the pH gradient is most conveniently formed by electrolysis of a solution containing a mixture of **carrier ampholytes** of low molecular mass and slightly differing isoelectric points, each of which will move to its isoelectric region in the electric field and remain there.

isoelectric-focusing electrophoresis a separation technique in which electrophoresis is effected in a gel slab at right angles to a preformed, stationary pH gradient generated by isoelectrically focused carrier ampholytes (*see* **isoelectric focusing**).

isoelectric fractionation any technique for fractionating proteins or other ampholytes using **isoelectric focusing**.

isoelectric pH an alternative term for **isoelectric point**.

isoelectric point or **isoelectric pH** *abbr.*: IEP or i.e.p.; *symbol*: pI; the pH of the solution in which a protein or other ampholyte has zero mobility in an electric field; hence the pH at which the protein or other ampholyte has zero net charge, i.e. no charges or an equal

number of positive and negative charges including those due to any extraneous ions bound to the ampholyte molecule. The pH value of the isoelectric point may depend on other ions, except hydrogen and hydroxide ions, present in the solution. *Compare isoionic point.*

isoelectric precipitation the precipitation of a protein at its **isoelectric point**, at which proteins are generally least soluble. It is useful in the fractionation of mixtures of proteins.

isoelectronic describing two or more chemical entities having the same number of electrons, especially valence electrons. *Compare isosteric.*

isoenergetic taking place at constant energy.

isoenzyme or **isozyme** any one of the multiple forms of an enzyme arising from a genetically determined difference in primary structure. Isoenzyme is an operational term to denote any one of a group of enzyme proteins with similar catalytic properties but separable by suitable methods, e.g. by electrophoresis, where knowledge of the nature of the multiplicity may be lacking. If the different enzyme proteins are derived from a common gene, then the term 'multiple forms' rather than 'isoenzymes' should be used. The term embraces **allelozyme** and **multilocus enzyme**. *Compare interconvertible enzyme.*

isoflavone 7-O-glucosyltransferase EC 2.4.1.170; an enzyme that catalyses the reaction between UDPglucose and isoflavone to form isoflavone 7-O-β-D-glucoside and UDP.

isoflavonoid any of various yellow- or orange-coloured hydroxyl or alkoxy derivatives of isoflavanone. They are plant pigments, present as glycosides or esters with tannic acid, have no recognized nutritional function, and are rapidly excreted in urine after ingestion. An example is genistein.

isoflurane 2-chloro-2-(difluoromethoxy)-1,1,1-trifluoroethane; a widely used nonflammable volatile anesthetic agent.

isoform any of several multiple forms of the same protein that differ in their primary structure, but retain the same function. They can be produced by different genes or by **alternative splicing** of RNA transcripts from the same gene.

isogenic or **isogenic** describing two or more individuals that possess exactly the same genotype. *See also syngenic.*

isoglucose *see high-fructose corn syrup.*

isoglutamine a trivial name for the α-amide of glutamic acid; glutamic 1-amide; γ-aminoglutaric acid; 4-amino-4-carbamoylbutanoic acid; H₂N-CO-CH(NH₂)-[CH₂]₂-COOH; a chiral α-amino acylamide. L-Isoglutamine (*symbol*: Glu-NH₂) can occur as an N-terminal amidated residue of proteins. Residues of D-isoglutamine (*symbol*: D-Glu-NH₂) are found in *Staphylococcus aureus* peptidoglycan. *Compare glutamine.*

isoglutaminyl the acyl group, H₂N-CO-CH(NH₂)-[CH₂]₂-CO-, derived from **isoglutamine**. *Compare glutaminyl.*

isoglutamyl a former name for **γ-glutamyl**.

isograft an alternative term for **syngenic graft**.

isohormone any of two or more structural variants of a polypeptide hormone that have the same hormonal action and are produced within the same organism, or at least within the same species of organism. —**isohormonal** *adj.*

isohydric describing solutions that have the same hydrogen-ion concentration, hydrogen-ion activity, or pH.

isohydric shift the opposing and counterbalancing changes in hydrogen-ion concentration occurring in peripheral tissues when dioxygen leaves the blood and carbon dioxide enters it. The hydration of CO₂ to H₂CO₃, catalysed by erythrocyte carbonic anhydrase, has a tendency to lower the blood pH. This tendency is counteracted in some degree by the simultaneous deoxygenation of hemoglobin; deoxyhemoglobin binds hydrogen ions more strongly than oxyhemoglobin, thus tending to raise the blood pH.

isoionic pH an alternative name for **isoionic point**.

isoionic point or **isoionic pH** the pH of a solution of a protein or other ampholyte from which all other ions have been removed, except hydrogen and hydroxide ions formed by dissociation of water or of the protein or ampholyte itself. *Compare isoelectric point.*

isoionic solution any solution of a protein or other ampholyte that contains no other ions except those arising from dissociation of the solute and the solvent.

isokinetic gradient any concentration and viscosity gradient used

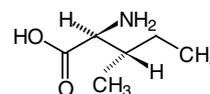

in centrifugation that allows particles (molecules) of the same density to sediment at a constant velocity at all distances from the centre of rotation.

isolate 1 to separate (a pure substance, a cell type, or a sample of a subcellular component) from a mixture or from naturally occurring material and then (usually) to characterize it; to separate and put into pure culture (a particular species or strain of a microorganism) from a mixture, sample, or biological specimen. **2** to remove a viable tissue or organ for the purpose of study or experiment. **3** (*in physics*) to disconnect (part of a circuit), or to prevent interaction between (circuits or components). **4** a group of similar microorganisms, especially a pure culture, obtained by isolation for study, experiment, or as an aid to diagnosis; something isolated. —**isolable** or **isolatable** *adj.*; **isolability**, **isolator** *n.*

isolectin any of two or more molecular forms of lectin, of the same origin, apparently with the same biological properties, and of very similar molecular masses, but of differing electrophoretic mobilities. They may be the products of closely related genes, or formed prior to or during isolation. In glycoprotein lectins, their differences may lie in the carbohydrate side chains.

isoleucinate 1 isoleucine anion; the anion, CH₃-CH₂-CH(CH₃)-CH(NH₂)-COO⁻, derived from **isoleucine**. **2** any salt containing isoleucine anion. **3** any ester of isoleucine.

isoleucine the trivial name for α-amino-β-methylvaleric acid; (2*R**,3*R**)-2-amino-3-methylpentanoic acid; CH₃-CH₂-CH(CH₃)-CH(NH₂)-COOH; an α-amino acid with two chiral centres. Because molecules of isoleucine possess a second chiral centre, at C-3, in addition to the chiral centre at C-2 common to all α-amino acids other than glycine, the enantiomers L-isoleucine, (2*S*,3*S*)-2-amino-3-methylpentanoic acid (*symbol*: I or Ile), and D-isoleucine, (2*R*,3*R*)-2-amino-3-methylpentanoic acid (*symbol*: D-Ile or D-Ile), are diastereoisomeric with those of **alloisoleucine**, (2*R**,3*S**)-2-amino-3-methylpentanoic acid. L-isoleucine is a coded amino acid found in peptide linkage in proteins; codon: AUA (not in mitochondria of fruit fly, mammals, or yeast) (anticodon: UAU); AUC or AUU (anticodon: UAG). In mammals, it is an essential dietary amino acid, and is both glucogenic and ketogenic. D-Isoleucine is not known to occur naturally.

L-isoleucine

isoleucine biosynthesis a pathway that commences with formation of α-aceto-α-hydroxybutyrate (I) from pyruvate and α-ketobutyrate (2-oxobutanoate, formed by removal of ammonia from threonine by serine dehydratase). I is converted via α,β-dihydroxy-β-methylvalerate to α-keto-β-methylvalerate (II). Isoleucine is then formed from II as a result of transamination with glutamate.

isoleucinium isoleucine cation; the cation, CH₃-CH₂-CH(CH₃)-CH(NH₃⁺)-COOH, derived from **isoleucine**.

isoleucino the alkylamino group, CH₃-CH₂-CH(CH₃)-CH(COOH)-NH-, derived from **isoleucine**.

isoleucyl the acyl group, CH₃-CH₂-CH(CH₃)-CH(NH₂)-CO-, derived from **isoleucine**.

isoliquiritigenin *see chalcone.*

isolog the US spelling of **isologue**.

isologous 1 of, relating to, or being two or more closely related chemical compounds in a series whose successive members differ in composition in a regular manner, other than by a difference of one methylene group. The term is now applied especially to compounds that have different atoms of the same valency at one or more positions in the molecule but are otherwise structurally identical, e.g. methionine and selenomethionine. **2** an alternative term for **isogenic**.

isologous association or **isologous binding** any association be-

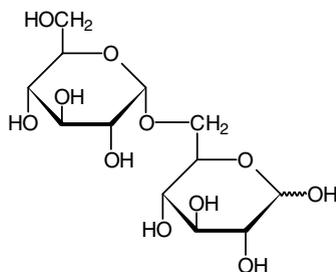

tween two identical protein subunits (i.e., **protomers**) in which the **domain of bonding** comprises two identical **binding sets**.

isologue or (*US*) **isolog** any of two or more **isologous** (def. 1) compounds.

isology the state or condition of being **isologous** (def. 1); chemical kinship among molecules or compounds.

isomaltase EC 3.2.1.10; *recommended name*: oligo-1,6-glucosidase; *systematic name*: dextrin 6- α -D-glucanohydrolase. An enzyme that hydrolyses 1,6- α -D-glucosidic bonds in dextrans and isomaltose produced after α -amylase degradation of starch and glycogen. The enzyme from intestinal mucosa also catalyses the reaction of EC 3.2.1.48 (see **sucrase**).

isomaltose the disaccharide 6- O - α -D-glucopyranosyl-D-glucose; it exists as the branching unit in **amlopectin**, **glycogen**, and some bacterial **dextrans**. Compare **maltose**.

isomaltulose the disaccharide 6- O - α -D-glucopyranosyl-D-fructofuranose.

isomer 1 (*in chemistry*) **molecular isomer** any of two or more compounds that have identical molecular formulas but differ in the nature of bonding of their atoms (**constitutional isomers**) or in the arrangement of their atoms in space (**stereoisomers**). **2** (*in physics*) **nuclear isomer** any of two or more nuclides that have the same proton number and the same mass (nucleon) number but different energy states.

isomerase any enzyme of EC class 5 that catalyses geometric or structural changes within one molecule. According to the type of isomeric change they catalyse, they may be called racemases or epimerases (EC subclass 5.1); *cis-trans*-isomerases (EC subclass 5.2); intramolecular oxidoreductases (EC subclass 5.3); intramolecular transferases (mutases) (EC subclass 5.4); or intramolecular lyases (EC subclass 5.5); other isomerases are placed in EC subclass 5.99.

isomeric of or pertaining to an **isomer**; pertaining to the phenomenon of, or displaying, **isomerism**.

isomeric state any of the states of an atomic nucleus having a different energy and observable half-life from those of other states of the same nucleus; the condition of being an **isomer** (def. 2).

isomeric transition *abbr.*: IT; the change of one nuclear isomer (see **isomer** (def. 2)) into another without change in either proton number (atomic number) or nucleon number (mass number), energy being lost in the form of gamma radiation; e.g. the decay of the metastable nuclide technetium-99m (half-life 6 h) to the unstable nuclide technetium-99 (half-life 2.1×10^5 years), which in turn decays to ruthenium-99 with emission of an electron.

isomerism the phenomenon of the existence of **isomers** in general, or the occurrence of molecular or nuclear isomers in a particular instance.

isomerization or **isomerisation** the act of changing or the process of change of one molecular isomer into another one. —**isomerize** or **isomerise** *vb*.

isometric 1 having identical dimensions. **2** (*in physiology*) of or pertaining to a contraction of a muscle that does not cause shortening of the muscle. **3** (*in crystallography*) having three mutually perpendicular axes of equal length; cubic.

isomorph a substance or organism that is **isomorphic** (def. 1) to another substance or organism.

isomorphic 1 or **isomorphous** of identical or similar form, shape, or

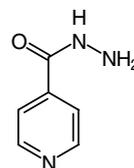

structure. **2** describing a type of alternation of generations in which morphologically identical generations occur in both diploid and haploid phases. It occurs mainly in algae. Compare **heteromorph**.

isomorphism 1 (*in biology*) similarity of form in organisms of different ancestry. **2** (*in chemistry*) similarity of crystalline form and structure between substances of similar composition or substances that can form a more or less continuous series of solid solutions.

isomorphous 1 an alternative term for **isomorphic** (def. 1). **2** displaying **isomorphism** (esp. def. 2).

isomorphous replacement method a method used to solve the phase problem in **X-ray diffraction** analysis of macromolecular structures. It involves combining one or more **heavy atoms** (def. 2) (which are strong scatterers) in a specific manner with the macromolecule in question and investigating their effects on the diffraction pattern. The heavy atom must not modify either the conformation or the crystal form of the macromolecule, i.e. the replacement must be isomorphous.

isoniazid 4-pyridinecarboxylic acid hydrazide; an antitubercular drug that may act by inhibiting the synthesis of the mycolic acids that are vital for the construction of the cell wall of the pathogen, *Mycobacterium tuberculosis*. Like related hydrazides it is highly hepatotoxic and no longer used. Its euphoric side effects led to the discovery of monoamine oxidase inhibitors.

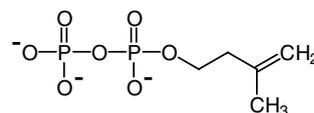

isoosmotic a variant spelling of **isosmotic**.

isopartitive (*in chromatography*) describing two or more solvents that bring about similar partitions of a given substance between the solvent and the stationary phase and hence result in R_f values that are the same or nearly so.

isopentenyl the *trivial name* for 3-methylbut-3-enyl, $\text{CH}_2=\text{C}(\text{CH}_3)-\text{CH}_2-\text{CH}_2-$, the alkenyl group formally derived from isopentenyl alcohol (i.e. 3-methylbut-3-en-1-ol) by loss of its hydroxyl group. Compare **prenyl**.

isopentenyl diphosphate *abbr.*: IDP; formerly called Δ^3 -isopentenyl pyrophosphate (*abbr.*: IPP); an isomer of dimethylallyl diphosphate and the key precursor of all **isoprenoids** (def. 2). See also **dimethylallyltransferase**, **isopentenyl-diphosphate Δ -isomerase**, **isoprene rule**.

isopentenyl-diphosphate Δ -isomerase EC 5.3.3.2; *systematic name*: isopentenyl diphosphate Δ^3 - Δ^2 -isomerase; *other name*: IPP isomerase. An enzyme in the pathway for the synthesis of cholesterol, terpenes, and prenyl groups; it catalyses the reversible reaction:

isopentenyl diphosphate = dimethylallyl diphosphate.

isopeptidase any peptidase catalysing the cleavage of an **isopeptide bond**.

isopeptide bond any peptide bond other than a **europeptide bond**, i.e. any amide bond formed between a carboxyl group of one amino-acid molecule or residue and an amino group of another, where either group occupies a position other than α (or both do so). Examples include peptide bonds formed from the β -carboxyl group of aspartic acid, the γ -carboxyl group of glutamate from the ϵ -amino

isopiestic

group of lysine, and from either the carboxyl group or the amino group of β -alanine.

isopiestic of, pertaining to, or characterized by equal pressures.

isopiestic vapour pressure method a method for the determination of the activity of water in a solution of a nonvolatile solute. The solution in question is equilibrated with a reference solution containing a nonvolatile solute for which the activity of water at different solute concentrations has been determined with high precision. The two solutions are placed in an enclosure at constant temperature until their vapour pressures are equal, i.e. the activity of water in both solutions is equal. They are then analysed for their solute contents, from which the activity of water in both of them can be calculated.

isoprenaline an alternative name for **isoproterenol**.

isoprene 2-methylbuta-1,3-diene; $\text{CH}_2=\text{C}(\text{CH}_3)-\text{CH}=\text{CH}_2$; a liquid hydrocarbon hemiterpene isolated from products of the pyrolysis of natural rubber, turpentine, etc., and widespread in plants although generally found only in extremely small amounts.

isoprene residue the branched-chain bivalent group, 3-methyl-2-butenylene; 3-methylbut-2-en-1,4-diyl; $-\text{CH}_2-\text{C}(\text{CH}_3)=\text{CH}-\text{CH}_2-$. It is formally derived by bond rearrangement from **isoprene** and constitutes the repeating unit of the molecular structures of prenyls and many other isoprenoids.

isoprene rule a rule, formulated by Wallach in 1887, that stated that many natural products are built up from isoprene carbon skeletons. It was modified to the **biogenetic isoprene rule** by Croatian-born Swiss chemist Leopold Ružička (1887–1976), who proposed that all terpenoids, steroids, etc. are synthesized from a precursor called 'active isoprene'. This precursor is now known to be **isopentenyl diphosphate**.

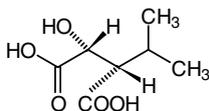

isoprene unit (in an *isoprenoid*) an **isoprene residue** or any branched five-carbon-atom moiety formally derived from an isoprene residue by chemical modification, e.g. by hydrogenation, hydroxylation, etc. It represents isopentenyl alcohol (i.e. 3-methylbut-3-en-1-ol), the diphosphate of which is the universal biogenetic precursor of isoprenoids.

isoprenoid 1 of, pertaining to, or being **isoprene** and its chemical relatives; having a molecular structure composed of, containing, or derived from linked **isoprene residues**. **2** any isoprenoid compound. Isoprenoids comprise a large and varied family of natural products, including carotenoids, phytol, prenyls, rubber, steroids, terpenoids, and tocopherols. Many substances contain both isoprenoid and nonisoprenoid components, e.g. the vitamins K.

isoprenyltransferase any of the enzymes within subclass EC 2.5.1, existing as α - β heterodimers, that add C_{15} or C_{20} carbon chains by **prenylation** near the carboxyl terminus of proteins. Examples include the nuclear lamins and Ras.

isopropyl *symbol*: iPr or Prⁱ; the alkyl group $(\text{CH}_3)_2\text{CH}-$, derived from propane. *Compare* **propyl**.

isopropylmalate either of the isomeric substances 2-isopropylmalate (i.e. 3-carboxy-3-hydroxy-4-methylpentanoate) or 3-isopropylmalate (i.e. 3-carboxy-2-hydroxy-4-methylpentanoate); they are enzymatically interconvertible intermediates in the biosynthesis of leucine in plants. *See also* **3-isopropylmalate dehydratase**.

(2*R*,3*S*)-3-isopropylmalic acid

3-isopropylmalate dehydratase EC 4.2.1.33; *systematic name*: 3-isopropylmalate hydro-lyase; an iron-sulfur protein, containing a [4Fe-4S] cluster, that catalyses the isomerization of 3-isopropylmalate to 2-isopropylmalate, by dehydration to 2-isopropylmaleate and rehydration to generate the isomer, in the pathway of L-leucine biosynthesis in plants. *See* **leucine and valine biosynthesis**.

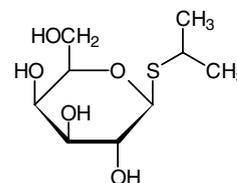

3-isopropylmalate dehydrogenase EC 1.1.1.85; *systematic*

isobestic point

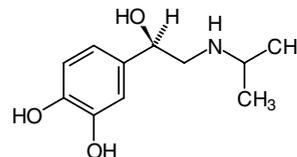

name: 3-carboxy-2-hydroxy-4-methylpentanoate:NAD⁺ oxidoreductase; an enzyme that catalyses the oxidation of 3-**isopropylmalate** by NAD⁺ (followed by loss of CO₂) to 4-methyl-2-oxopentanoate, in the pathway of L-leucine biosynthesis in plants. *See* **leucine and valine biosynthesis**.

2-isopropylmalate synthase EC 4.1.3.12; *systematic name*: 3-carboxy-3-hydroxy-4-methylpentanoate 3-methyl-2-oxobutanoate-lyase (CoA-acetylating); an enzyme that condenses acetyl-CoA with 3-methyl-2-oxobutanoate to form 2-isopropylmalate, in the pathway of L-leucine biosynthesis in plants. *See* **leucine and valine biosynthesis**.

isopropyl β -thiogalactoside *abbr.*: IPTG; isopropyl β -D-1-thiogalactopyranoside; an inducer of β -galactosidase in bacteria; it also induces the *lac* operon by binding and inactivating the *lac* repressor. It is used in cloning techniques to enhance expression of DNA cloned into vectors containing the *lac* operon.

isoproterenol or **isoprenaline** 3,4-dihydroxy- α -[(isopropylamino)methyl]benzyl alcohol; the synthetic isopropyl analogue of epinephrine. It is a selective agonist of β adrenoceptors, but does not discriminate between β_1 and β_2 subtypes.

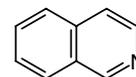

isopycnic of, pertaining to, or characterized by equal densities.

isopycnic banding the formation during **isopycnic centrifugation** of one or more bands composed of molecules that have the same density as that of the solvent at that position in the gradient; the process of separating or purifying substances by forming such bands.

isopycnic centrifugation or **band centrifugation** or **density-gradient centrifugation** or **density-gradient sedimentation equilibrium** a separation technique in which macromolecules are subjected to a centrifugal field in a solvent containing a density gradient. The macromolecules will sediment or float and arrange themselves in bands (isopycnic bands) in the column of solvent where the density of the solvent is the same as that of the particular macromolecule. *Compare* **isokinetic gradient**.

isoquinoline 2-benzazine; benzo[*c*]pyridine; a bicyclic, aromatic, nitrogen-containing compound. Many alkaloids contain an isoquinoline ring system.

isoquinolinesulfonylmethylpiperazine *see* H7.

isobestic point any wavelength at which the molar **absorption coefficients** of two or more particular chemical species are equal, i.e. their absorption spectra intersect. All mixtures (or solutions) of two or more such species, having the same total concentration, will then exhibit absorption spectra that pass through the isobestic point, provided the species do not interact.

isoschizomer any of two or more restriction endonucleases from different sources that recognize the same sequence in a DNA molecule and display identical specificity of cleavage within that sequence. The term is sometimes extended to include those enzymes that cleave at different sites within the sequence recognized, or that respond to methyl groups on different bases in the sequence. Examples are *MspI* and *HpaII*, both of which cleave the unmethylated sequence CCGG. —**isoschizomeric** *adj.*

isosemantic substitution the incorporation of an amino-acid residue into its normal position in a polypeptide chain in response to a mutated but synonymous codon.

isosmotic or **isoosmotic** (*of two or more solutions*) having equal osmotic pressure; having the same osmotic pressure as another solution. *See also isotonic* (def. 2).

isostere or **isoster** any of two or more **isosteric** chemical species.

isosteric (*of two or more chemical species*) having the same, or similar, shape and size, e.g. L-threonine and L-valine; having the same number of valence electrons arranged in a similar manner. *Compare isoelectronic*. —**isosterism** *n.*

isotachophoresis or **isotachoelectrophoresis** or **displacement electrophoresis** a method for separating ion species in which all ions under observation are given the same migration velocity; moreover, they all have the same sign and a common counterion. The sample ions are introduced as a zone between a leading electrolyte, whose ions have a higher mobility than any of the sample ions, and a terminating electrolyte, whose ions have a lower mobility than any of the sample ions.

isotactic of, relating to, or having stereochemical regularity in the repeating units of a polymer. *Compare syndiotactic*.

isotherm or **isothermal** any line on a graph, or diagram, that connects points of equal temperature.

isothermal 1 (*of a process or reaction*) occurring at constant temperature. **2** of or pertaining to an isotherm. **3** *an alternative name for isotherm*.

isothiocyanate any organic compound containing the monovalent group $-N=C=S$. *Compare thiocyanate*.

isotocin or (*formerly*) **isotocine** [Ser⁴, Ile⁸]oxytocin; the somewhat less potent structural variant of **oxytocin**. It is present in many bony fish in place of oxytocin, hence it is sometimes known as **ichthyotocin**. *See also mesotocin*.

isotope any of two or more nuclides having the same number of neutrons but, usually, different numbers of protons and therefore differing in atomic number.

isotonic 1 of, or having the same tension; used especially of muscular contraction occurring in the absence of significant resistance and accompanied by marked shortening of the muscle fibres. *Compare isometric* (def. 2). **2** having the same osmotic pressure as some particular solution, especially one in a cell or body fluid; **isosmotic**. *Compare hypertonic, hypotonic*. **3** of, relating to, or being an **isotone** or **isotone**.

isotonically under **isotonic** (def. 1) conditions.

isotonicity the state or quality of being **isotonic** (def. 2); the degree of osmotic pressure.

isotope any of two or more **nuclides** that have the same **proton number**, i.e. that are nuclides of the same chemical element and thus display qualitatively the same chemical properties (for quantitative differences, *see isotope effect*). Isotopes with a given proton number usually have different **nucleon numbers** and thus characteristically usually have different relative atomic masses. In some instances, however, two isotopes of an element are **isomeric**, i.e. they have the same nucleon number (and hence the same relative atomic mass) but differ instead in their nuclear energy levels, the isotope with the higher level being **metastable** (def. 3). For the majority of elements, isotopes occur naturally and at more or less constant relative abundances; additional isotopes can be produced artificially. In general, any given element possesses both stable and unstable isotopes, although there are no stable ones for elements of high proton number; conversely, the naturally occurring isotopes of elements of lower proton number are, with a few exceptions, all stable. Metastable and unstable isotopes undergo radiative decay and are collectively termed **radioactive isotopes**, or **radioisotopes**. (*Note*: In common parlance the term isotope is often used loosely as a syn-

onym of nuclide irrespective of its proton number.) *Compare hetero-*
tope, isobar, isotone. —**isotopic**, *adj.*

isotope abundance the number of atoms of a particular isotope in a mixture of the isotopes of an element in a sample, expressed as a percentage of all the atoms of that element in the sample. *Compare isotope ratio*.

isotope dilution analysis an accurate method for measuring the concentration of an element, or a compound of that element, in a system by adding a known amount of a different isotope, or a labelled compound, and then measuring its concentration in a sample withdrawn from the system after mixing.

isotope effect any variation in some chemical, physicochemical, or biochemical property of a molecular entity that is detectable on isotopic substitution of an atom or atoms of the entity, e.g. variation in reaction rate, in chromatographic mobility, or in binding to macromolecules. For a given pair of isotopes, 'light' and 'heavy', the effect may be expressed quantitatively either (in the **kinetic isotope effect**) as the ratio of the rate constants, $k_{\text{light}}/k_{\text{heavy}}$, or (in the **equilibrium isotope effect**) as the ratio of the equilibrium constants, $K_{\text{light}}/K_{\text{heavy}}$, for two chemical reactions that differ only in the isotopic composition of one or more of their otherwise chemically identical components. The magnitude of the effect depends on the relative difference in atomic mass of the isotopes in question; thus it is the greatest by far for isotopes of hydrogen.

isotope exchange any chemical reaction in which the reactants and products are chemically identical but of different isotopic composition. In such a reaction the isotope distribution tends towards equilibrium.

isotope farming *an informal term sometimes used to describe biological techniques for the large-scale preparation, usually for sale, of radioisotope-labelled biochemicals, especially when a number of such compounds are obtainable in the same operation, e.g. the simultaneous preparation of a number of ¹⁴C-labelled compounds from ¹⁴CO₂ by photosynthesis in whole leaves or whole plants.*

isotope ratio or **isotopic ratio** the ratio between the numbers of atoms of any two isotopes of a given element in a particular preparation, sample, or substance. *Compare isotope abundance*.

isotope-ratio mass spectrometer a **mass spectrometer** designed specifically for the determination of **isotope ratios**.

isotopic 1 of, relating to, or being an **isotope** or isotopes. **2** being or containing a less common or artificial isotope, especially as a label or tracer. **3** (*especially of techniques*) using or depending on isotopes. —**isotopically** *adv.*

isotopically coded affinity tag *abbr.*: ICAT; a reagent used for quantitation of differential protein expression. The proteins in two samples to be compared are labelled with a reagent containing a thiol-specific reactive group that binds to the side chain of reduced cysteines, with a linker group that is either deuterated or non-deuterated, and a group such as biotin that allows affinity isolation of the ICAT-labelled peptides from complex mixtures using affinity chromatography. The isolated and tagged peptides are analysed by mass spectrometry.

isotopy the phenomenon of the existence of isotopes in general; or the fact or condition of being isotopic in a particular instance.

isotropic or **isotropous 1** (*in physics*): exhibiting uniform properties when measured along axes in all directions. *Compare anisotropic*. **2** (*in biology*) not having predetermined axes of growth. —**isotropically** *adv.*; **isotropy** or **isotropism** *n.*

isotropic band or **I-band** *see sarcomere*.

isotropic motion the random tumbling of a chemical species about its three axes.

isotropous *an alternative word for isotropic*.

isotypic specificity any antigenic specificity that is the same in a given protein in all normal individuals of the same animal species. For example anti-rabbit gamma globulins prepared in another animal species do not distinguish between gamma globulins from different rabbits.

isotypic variation structural variability of any one antigen that is common to all members of the same species.

isovaleric acidemia a hereditary metabolic disease of humans, due to various mutations in **isovaleryl-CoA dehydrogenase**. Of variable

severity, it is characterized by metabolic acidosis and excessive urinary excretion of isovaleric acid or isovaleryl conjugates.

isovaleryl-CoA dehydrogenase *abbr.*: IVD; EC 1.3.99.10; a mitochondrial matrix flavoprotein enzyme of the pathway for degradation of leucine. It catalyses the oxidation of 3-methylbutanoyl-CoA to 3-methylbut-2-enoyl-CoA. The flavin is FAD.

isozyme *an alternative word for isoenzyme.*

isozymogen any precursor of an isozyme.

ISSD *abbr. for* infantile sialic acid storage disease.

ISWI *abbr. for* initiation switch; an ATPase protein component of NURF that with GAGA factor initiates expression of the Hsp70 gene in *Drosophila*.

IT *abbr. for* isometric transition.

itaconate methylenesuccinate; methylenebutanedioate; the dianion $^{-}\text{OOC}-\text{CH}_2-\text{C}(\text{=CH}_2)-\text{COO}^{-}$; a constitutional isomer of **citraconate**. It is a metabolite of strains of *Aspergillus terreus*, which can yield it in large amounts by decarboxylation of *cis*-aconitate. It is a comparatively reactive compound, with properties useful in the manufacture of synthetic resins and plastics.

ITAM *abbr. for* immunoreceptor tyrosine-based activation motif; a consensus sequence for src-family tyrosine kinases. ITAMs are found in the cytoplasmic domains of several signalling molecules including the signal transduction units of lymphocyte antigen receptors and of Fc receptors.

iterative process a process in which a set of steps or instructions is repeatedly executed until a predefined or natural end point is reached. For example, in sequence analysis PSI-BLAST (position-specific iterated-BLAST) runs the BLAST program multiple times until no further matches are identified above a significance threshold.

iteron any sequence of nucleotides in the duplex DNA of certain lambdaoid phages that is reiterated several times with only minor changes. These repeated sequences, of 13–19 base pairs, are usually separated by short spacer sequences, each having internal dyad symmetry.

ITF *abbr. for* intestinal trefoil factor.

ITIM *abbr. for* immunoreceptor tyrosine-based inhibitory motif; any of various sequences that are present in the cytoplasmic domains of certain cell surface molecules e.g. Fc γ , inhibiting NK cell receptors that mediate inhibitory signals.

+itis *suffix forming nouns* denoting inflammation of the (specified) organ, tissue, etc.

ITP *abbr. for* 1 inosine (5'-)triphosphate. 2 isotachophoresis.

itraconazole a complex derivative of triazole, useful as an antimycotic. It inhibits cytochrome P450-dependent enzymes, thereby impairing the synthesis of ergosterol.

+ity *suffix forming nouns* meaning a property of a substance; e.g. absorptivity, density, solubility.

IU *abbr. for* International Unit (*preferred alternative to i.u. or u*).

IUB *abbr. for* International Union of Biochemistry; renamed (1992) International Union of Biochemistry and Molecular Biology (IUBMB).

IUBMB *abbr. for* International Union of Biochemistry and Molecular Biology.

IUdR or **IUDR** *abbr. for* 5-iododeoxyuridine (IdUrd preferred).

IUPAB *abbr. for* International Union of Pure and Applied Biophysics.

IUPAC *abbr. for* International Union of Pure and Applied Chemistry.

iupaciubin alanyl-lysyl-glutamyl-tyrosyl-leucine; a pentapeptide containing one residue each of the five main types of amino acid found in peptides and proteins, i.e. small neutral, basic, acidic, aromatic, and lipophilic. It exists only on paper, and was designed as a model to illustrate nomenclature recommendations relating to the modification of named peptides. Its name symbolizes the cooperation between IUPAC and IUB.

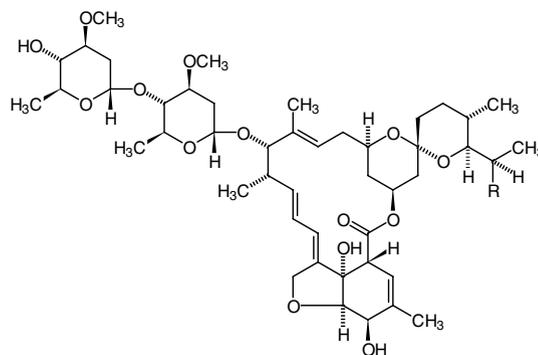

IUPAP *abbr. for* International Union of Pure and Applied Physics.

IUPHAR *abbr. for* International Union of Basic and Clinical Pharmacology.

IV or **i.v.** *abbr. for* intravenous or intravenously.

IVD *abbr. for* isovaleryl-CoA dehydrogenase.

ivermectin 22,23-dihydroabamectin; 22,23-dihydroavermectin B₁; a semisynthetic material derived from **abamectin** and used as an anthelmintic in both clinical and veterinary practice, especially against onchocerciasis. It is used extensively as a once-a-month pill against heartworm in dogs.

component B_{1a}, R = C₂H₅
component B_{1b}, R = CH₃

ivermectin

iVI *symbol for* the isovaleryl group, (CH₃)₂CH-CH₂-CO- (*alternative to VI*).

Jj

j symbol for electric current density (alternative to *J*).

J symbol for 1 joule. 2 J chain (of an immunoglobulin).

J symbol for 1 coupling constant. 2 flux (def. 2). 3 electric current density (preferred alternative to *j*).

jack bean 1 an annual tropical American leguminous plant, *Canavalia ensiformis*, grown in the USA for forage. 2 the seed of this plant. It is the source of the globulin **canavalin**, the toxic amino acid L-canavanine, the lectin **concanavalin A**, and the enzyme **urease**.

jack-knife (*in phylogeny*) a statistical method for assessing confidence levels of inferred phylogenetic relationships and the variance of estimated evolutionary parameters, in which values are iteratively and randomly removed, each new data set being used to recalculate the relationships. A **consensus tree** is built after multiple repetitions, and the degree of variance of the sample is determined by comparing each branch of the original tree with the number of times it was found by the jack-knife process.

Jacob–Monod model a model of genetic regulation of protein synthesis in prokaryotes whereby the structural genes that determine the organization of the proteins are controlled by other regions of DNA upstream from the structural genes. The latter consist of a regulator gene and a **control site**, which comprises the **promotor** (*p*) and **operator** (*o*). The regulator gene produces a **repressor** (*r*), which interacts with the operator. The operator and its associated genes are called an **operon**. The structural genes are transcribed into a single mRNA coding for the several proteins. An mRNA coding for more than one protein is known as a **polygenic** or **polycistronic** transcript. The first example was the **lac operon** but the model has been used to elucidate many other such phenomena, e.g. the **tryptophan** and **arabinose** operons. The repressor can be either inactivated (**induction**) or activated (**repression**) by specific metabolites. While the model has been helpful in explaining the mode of expression of genes in eukaryotes, operons have not been described in them. [After François Jacob (1920–) and Jacques Monod (1910–76), French molecular biologists.]

Jagged-1 *see* **Alagille syndrome**.

JAK *abbr.* for Janus kinase; any of three cytosolic protein tyrosine kinases that bind the intracellular domains of certain membrane receptors. **JAK1** is activated by binding on the non- γ polypeptide of receptors for the interleukins IL-2, IL-4, IL-7, IL-9, and IL-15. It phosphorylates **STAT** proteins other than STAT 5a and 5b. **JAK2** is activated on binding receptors for somatotropin, several cytokines, and leptin. It then phosphorylates **STAT** proteins, which dimerize and enter the nucleus to activate specific genes. **JAK3** is activated on binding the γ polypeptide of receptors for IL-2, IL-4, IL-7, IL-9, and IL-15. It phosphorylates STAT 5a and 5b. Several mutations in the gene at 19p13 for **JAK2** account for $\approx 7\%$ of patients with severe combined immunodeficiency (SCID).

JalView *see* **alignment editor**.

Jamaican vomiting sickness a syndrome of sickness, vomiting, and poisoning of the nervous system, associated with profound hypoglycemia, metabolic acidosis, and excessive urinary excretion of butyrate and glutarate, induced by consumption of the unripe fruit of the **ackee**, the toxic principle of which is **hypoglycin**.

Janus kinase *see* **JAK**.

jasmonic acid a plant hormone that consists of a C_{12,1} fatty acid that is unsaturated between C-9 and C-10 and contains a 6-oxocyclopentane ring formed by C-3 to C-7. Derived metabolically from α -linolenic acid, it inhibits growth processes in many tissues, modulates genes involved in development, and plays a role in plant resistance to insects and disease. It is metabolized by hydroxylation and conjugation to the branched chain α -amino acids. As methyl jasmonate and the structurally related *cis*-jasmonate, it is the fragrant component of oil of jasmine, derived from jasmine plants (*Jasminum* spp.).

jaundice or **icterus** a yellowing of the skin and/or of the whites of the eyes indicating an excess of bilirubin in the blood. Jaundice may be classified into three types depending on cause: **obstructive jaundice**,

in which the passage of bile from the liver to the intestine is obstructed; **hepatocellular jaundice**, in which there is disease and/or inflammation of liver cells thus diminishing their ability to secrete bile pigments into the bile passages; and **hemolytic jaundice**, in which there is an excessive breakdown of erythrocytes in the body and hence an excess of bile pigments.

Java *see* **programming language**.

javascript *see* **programming language**.

JCBN *abbr.* for (IUPAC–IUB or IUPAC–IUBMB) Joint Commission on Biochemical Nomenclature. *See also* **CBN**.

J chain or **J piece** *abbr.* for joining chain or joining piece; a 15 kDa, cysteine-rich polypeptide occurring in **immunoglobulin A** (IgA) and **immunoglobulin M** (IgM) molecules. It cross-links the monomeric immunoglobulin moieties to form a dimer or pentamer in IgA and IgM, respectively. It is not to be confused with the J segment of an immunoglobulin gene (*see* **joining gene**).

jejunum the part of the small intestine of mammals between the duodenum and the ileum. —**jejunal** *adj.*

jekyll a zebrafish mutant phenotype that shows defective initiation of heart-valve formation. The mutation involves a homologue of the *Drosophila sugarless* gene that encodes a UDP-glucose dehydrogenase required for production of heparan sulfate, chondroitin sulfate, and hyaluronic acid.

jelly roll a protein fold consisting of two antiparallel β -sheets placed one above the other to form a sandwich structure. The polypeptide chain follows a route in which successive β -strands alternate between the two sheets. If the β -strands are numbered β_1 , β_2 , etc., and the β -sheets numbered in parentheses, as (1), (2), etc., the structure of the motif can be represented as loop- β_1 (1)-loop- β_2 (2)-loop- β_3 (1)-loop- β_4 (2)-loop- β_5 (1), etc. The jelly-roll fold was first observed in viral coat proteins, but has since been found in other proteins.

Jerne's theory of immunity *an alternative name for natural-selection theory of immunity*.

jervine a steroidal alkaloid, found in plants of the genus *Veratrum*, that inhibits cholesterol biosynthesis. Pregnant ewes that ingest these plants give birth to lambs with congenital malformations.

J gene *abbr.* for joining gene.

JIP *abbr.* for JNK-interacting protein; *other name*: kinesin-binding protein; any of three proteins (JIP1 to JIP3) that form part of the **JNK** signalling pathway and are present in cells and organisms that contain **kinesin** light chains (KLC). JIP1 and JIP2 are highly homologous and interact through their C-terminal regions with tetra-tricosapeptide sequences of KLC. JIP3 is not homologous with the others and interacts through internal sequences with the same sequences in KLC as the others. They are adaptor molecules between kinesins and their cargo. They also bind MAP kinase, MAP kinase kinase, and MAP kinase kinase kinase.

JIPID *abbr.* for Japan International Protein Information Database; *see* **sequence database**.

JIT *abbr.* for Just In Time (compiler); a program that converts **Java** to local machine code at runtime.

JM101 one of a series of *E. coli* strains that support the growth of bacteriophage M13 vectors. The F' episome carries *lacZM15* making them suitable for alpha-complementation with plasmids encoding the N-terminal peptide of β -galactosidase.

JM109 an *E. coli* strain from the same series as **JM101** that carries *recA1* and *endA1* mutations.

JmjC the C-terminal domain of jumonji protein. *See* **jumonji**.

JmjN the N-terminal domain of jumonji protein. *See* **jumonji**.

JNK *abbr.* for c-Jun N-terminal kinase; *other name*: stress-associated protein kinase (*abbr.*: SAPK); a nuclear protein serine/threonine kinase, belonging to the **MAP kinase** family, that phosphorylates residues on the N-terminal region of the transcription factor c-Jun (also known as AP1). It is activated by binding to **Cdc42** and regulates cell growth and differentiation, and apoptosis. It is also activated by UV light, thermal stress, and tumour necrosis factor α .

JNK-interacting protein *see* JIP.

Job's method *an alternative name for* continuous variation.

Johnston-Ogston effect a phenomenon occurring in sedimentation velocity experiments when two or more solutes are present in a mixture and their sedimentation coefficients are mutually concentration-dependent. It follows that the sedimentation coefficient of the more slowly sedimenting component is less in the plateau region containing both species than it is in the plateau region between the boundaries, resulting in a higher concentration of the more slowly moving component in the plateau region between the boundaries. As a consequence, the apparent concentration of the faster moving species, based on the concentration difference between the two plateaus, is too low, while the apparent concentration of the more slowly moving species is too high. [After Alexander George Ogston (1911–96) and Joseph Percy Johnston (1923–76), British biochemists.]

joinase *or* **joining enzyme** *a former name for* DNA ligase (ATP) and DNA ligase (NAD⁺). *See* DNA ligase.

joining gene *or* **J segment** *abbr.:* J gene; any of approximately five germ-line genes concerned in coding for immunoglobulin synthesis. The J genes code for the fourth framework region of both light and heavy immunoglobulin chains and for part of the third hypervariable region of the light chain. *Compare* J chain.

joining peptide an acidic, 18-residue peptide situated between γ_3 -MSH and ACTH in proopiomelanocortin.

Jones-Mote sensitivity a weak, delayed-type hypersensitivity of the skin seen on challenge a few days after priming with soluble protein in aqueous solution or in incomplete Freund's adjuvant. The cells infiltrating the lesion characteristically include a high proportion of basophils.

joule *symbol:* J; the SI derived unit of energy, work, or heat, equal to a force of one newton acting over a distance of one metre; i.e. 1 J = 1 N m = 1 W s. The joule is equivalent to 10⁷ ergs and is the energy dissipated by one watt in one second. [After James Prescott Joule (1818–89), British physicist.]

J piece *an alternative name for* J chain.

J segment *an alternative name for* joining gene.

jumonji a gene of mice and humans that is required for neural-tube formation. The protein contains an N-terminal JmjN domain, a dead ringer domain, and a C-terminal JmjC domain. The two Jmj domains form a functional unit. The JmjC domain also occurs alone in hairless, retinoblastoma protein-binding protein 2, and several putative chromatin-binding proteins. In the mouse, mutations in *jumonji* cause embryonic lethality.

jumping gene *an informal term for* transposon.

JUN a gene family encoding nuclear transcription factors; *v-jun* is the oncogene from avian sarcoma virus ASV17 (named from *junana*, Japanese for seventeen). *JUN* encodes transcription factor AP1; it belongs to the *fos/jun* family, and is rapidly and transiently expressed on stimulation of cells by mitogens. The product, Jun, forms heterodimers with Fos, and these, together with Jun homodimers, bind to the AP1 consensus site. Jun is a leucine zipper protein, which also contains basic sequences essential for DNA binding. In resting cells Jun is phosphorylated on four serines and one threonine; removal of one or more of these phosphates leads to increased binding to the AP1 promoter site. Jun has five motifs.

junction potential *see* liquid-junction potential.

'junk' DNA *see* selfish DNA hypothesis.

juvenile hormone *or* **neotenin** any insect hormone, produced in the corpora allata glands, that functions to keep the insect in the larval (juvenile) stage. At least three are known; all are derivatives of farnesoic acid. They have potential as insect control agents.

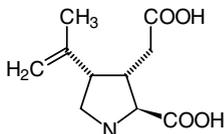

juvenile-hormone esterase *see* methylesterase.

juvenile macular degeneration *an alternative name for* Stargardt macular dystrophy.

juxtacrine stimulation a mode of intercellular communication established by the binding of a membrane-anchored growth factor on one cell to its receptor on an adjacent cell, e.g. in the case of proto-oncogenic growth factor-*a* (*see* transforming growth factor). Unlike endocrine, paracrine, or autocrine modes there is no diffusible factor.

Kk

- k** symbol for kilo+ (SI prefix denoting 10^3).
- k** symbol for **1** rate constant; the various associated terms are distinguished by subscripts and/or superscripts (see individual entries below). **2 Boltzmann constant**. See also **k(T)**.
- k** symbol for pH-independent value of the rate constant k .
- k₀** symbol for catalytic constant (of an enzyme); alternative to k_{cat} .
- k_A**, **k_B** symbols for the specificity constants of substances A and B.
- k_{app}** symbol for the apparent value of the rate constant k .
- k_{cat}** symbol for catalytic constant (of an enzyme); alternative to k_0 .
- k_f**, **k_r** symbols for the forward and reverse rate constants, respectively, for the i th step in an enzyme reaction.
- k_{ij}** symbol for the rate constant for the step from E_i to E_j in an enzyme reaction.
- K** symbol for **1** potassium. **2** kelvin. **3** a residue of the α -amino acid L-lysine (alternative to Lys). **4** a residue of an incompletely specified base in a nucleic-acid sequence that may be guanine, or either thymine (in DNA) or uracil (in RNA). **5** phyloquinone. **6** (*in computing*) indicating multiplied by 1024 ($= 2^{10}$).
- K562** an erythromegakaryoblastic leukemia cell line. Cells in culture can be induced into erythroid development by treating them with sodium butyrate.
- K** symbol for **1** (thermodynamic) equilibrium constant (of a chemical reaction); the various associated terms are distinguished by subscripts and/or superscripts (see individual entries below). **2** kinetic energy. **3** kerma (kinetic energy released in matter). **4** luminous efficacy.
- K'** symbol for apparent (concentration) equilibrium constant.
- K^o** or **K^e** symbol for standard equilibrium constant.
- K₁**, **K₂**, ... **K_n** symbols for the first, second, ... n th equilibrium (dissociation or association) constants, respectively, of the same substance.
- K_a**, **K_a** symbols for the thermodynamic and apparent acid dissociation constants, respectively.
- K_A** symbol for activator constant.
- K_b**, **K_b** symbols for the thermodynamic and apparent basic dissociation constants, respectively.
- K_c** symbol for equilibrium constant with respect to concentration (concentration equilibrium constant).
- K_i** symbol for inhibition constant (inhibition type unspecified); the reactant to which it relates may be indicated by an appropriate subscript, e.g. K_{iA} .
- K_{ic}** symbol for competitive inhibition constant.
- K_{iu}** symbol for uncompetitive inhibition constant.
- K_m** symbol for Michaelis constant (also called **Michaelis concentration** or, more appropriately **Michaelis–Menten constant**); the reactant to which it relates may be indicated by an appropriate subscript, e.g. K_{mA} .
- K_s** symbol for substrate dissociation constant; the reactant to which it relates may be indicated by an appropriate subscript, e.g. K_{sA} .
- K_s'** symbol for salting out constant.
- K_w** symbol for the ion product of water.
- kainate receptor** a type of neuroexcitatory membrane receptor characterized by its specific agonist ligand, kainate (see **glutamate receptor**), and for which glutamate may be the endogenous ligand. The receptor is coupled to Na^+/K^+ channels in the cell membrane, which are opened when activated by agonist.
- kainic acid** (2*S*,3*S*,4*S*)-2-carboxy-4-(1-methylethenyl)-3-pyrrolidineacetic acid; digenic acid; a cyclic analogue of L-glutamic acid

obtained from *Digenea simplex* (a red alga). It is an amino-acid agonist for the **kainate receptor**, is a neurotoxin, and has anthelmintic properties.

kairomone any of a heterogeneous group of chemical messengers that are emitted by organisms of one species but benefit members of another species; they are commonly nonadaptive or maladaptive to the emitter. They include attractants, phagostimulants, and other substances that mediate the positive responses of, e.g., predators to their prey, herbivores to their food plants, and parasites to their hosts. Compare **allomone**, **pheromone**.

KAL a human X-chromosome gene that when mutated produces Kallmann syndrome of hypogonadotropic hypogonadism and anosmia. It encodes a glycoprotein (680 amino acids) of the extracellular matrix that is responsible for migration of gonadotropin-releasing hormone (GnRH)-producing neurons and of olfactory neurons. It contains an N-terminal four-disulfide-bond core domain, similar to that of some protease inhibitors, and in the C-terminal region two fibronectin domains (type III) similar to those present in a variety of N-CAMs.

kalata B a uterotonic circular peptide of 29 amino acids extracted from the African plant *Oldenlandia affinis* and several members of the Rubiaceae and Violaceae families. It contains three disulfide bonds and forms only beta strands.

kalinin 1 another name for laminin 5 (see **laminin**). **2** a filament-associated protein of the **laminin** family, e.g. (precursor) human kalinin B1, also known as nicein B1 or (most commonly) laminin B1k.

kalinin a multidomain cytoskeletal protein that functions as a guanine nucleotide exchange factor. It contains 2959 amino acids, which form 87 spectrin repeats, two Dbl and two pleckstrin homology regions, two Ig-like regions, two SH3 regions, and a kinase domain.

kallidin an alternative name for lysylbradykinin; see **bradykinin**.

kallikrein any of two groups of serine endopeptidases that are widely distributed in mammalian tissues and body fluids, including blood. **Plasma kallikrein** (EC 3.4.21.34; also called kininogenin or Fletcher factor or serum kallikrein) cleaves Arg-|-Xaa and Lys-|-Xaa bonds, including Lys-|-Arg and Arg-|-Ser bonds in kininogen to produce bradykinin, and activates blood coagulation factors XII and VII; it is formed from prekallikrein by factor XIIa. **Tissue kallikrein** (EC 3.4.21.35; other names: glandular kallikrein; kininogenin) catalyses the preferential cleavage of Arg-|-Xaa bonds in small molecule substrates. Its highly selective action to release kallidin (lysyl-bradykinin) from **kininogen** involves hydrolysis of Met-|-Xaa or Leu-|-Xaa. The rat enzyme is unusual in liberating bradykinin directly from autologous kininogens by cleavage at two Arg-|-Xaa bonds.

kallistatin or **protease inhibitor 4** an acidic protein (in plasma) of the **serpin** family, expressed widely in human tissues. It inhibits tissue **kallikrein**, forming a 1:1 complex with it.

Kallmann syndrome see **KAL**.

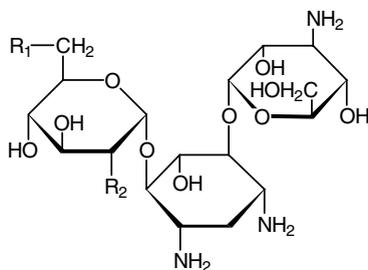

kanamycin an aminoglycoside antibiotic complex produced by *Streptomyces kanamyceticus*. It is made up of three components: kanamycin A (in which $R_1 = \text{NH}_2$, $R_2 = \text{OH}$; see structure), the major component, often designated as kanamycin; and two minor congeners, kanamycin B (R_1 and $R_2 = \text{NH}_2$) and kanamycin C ($R_1 = \text{OH}$, $R_2 = \text{NH}_2$). Kanamycin causes misreading during protein synthesis in bacteria, but its target site on the ribosome is apparently different from that of streptomycin. See also **kanosamine**.

kanosamine 3-amino-3-deoxy-D-glucose; an amino sugar present in **kanamycin** and other antibiotics, and as free carbohydrate in fermentation broths of *Bacillus aminoglucosidicus*.

K antigen see **capsular antigen**.

kaolin or **china clay** a finely powdered hydrated aluminium silicate; it is useful as an adsorbent.

Kaposi's sarcoma a skin cancer endemic to equatorial Africa and often occurring in AIDS patients. [After Moritz Kaposi (1837–1902), Austrian dermatologist.]

kanamycin

kappa *symbol*: κ (lower case) or K (upper case); the tenth letter of the Greek alphabet. For uses see **Appendix A**.

kappa B or **κB** an element common in eukaryotic promoters. The consensus sequence is GGRNNYYCC, e.g. GGGGACTTTC in mouse and human.

kappa chain or **κ chain** *symbol*: κ; one of the two types of **light chain** found in human immunoglobulins, the other type being a **lambda chain**. See also **Bence-Jones protein**.

kappa convention a way of denoting single ligating atom attachments of a polyatomic ligand to a coordination centre such as a metal ion. Ligands are indicated by the italic element symbol preceded by a Greek kappa, κ. A right superscript numerical index indicates the number of such attachments. See **donor atom symbol**.

kappa factor a protein that causes termination of transcription of various bacteriophage DNAs, including those of T4, T5, and T7, by *Escherichia coli* DNA-dependent RNA polymerase in a DNA site-specific manner. It is a dimer of two apparently identical 17 kDa peptide chains.

kappa particle a cell of any of several species of *Caedibacter* present in the cytoplasm of killer strains of *Paramecium aurelia*. (*Caedibacter* is a genus of Gram-negative bacterial obligate endosymbionts of this protozoan.) When kappa particles (and/or toxic constituents or products of them) are released by killer paramecia they may be lethal to sensitive paramecia (which lack both the endosymbiont and a protective genetic factor).

Karplus curve a curve describing the relation of the nuclear magnetic resonance spin-spin coupling constant and the dihedral angle. [After Martin Karplus (1930–).]

Karplus relation an equation describing the relation between the magnitude of the nuclear magnetic resonance spin-spin coupling constant, J , across three bonds and the dihedral angle, θ , about the central bond. It is:

$$J = A + B\cos\theta + C\cos^2\theta,$$

where A , B , and C are coefficients that depend on the electronegativity of the substituents.

karyo+ or **caryo+** *comb. form* denoting the nucleus of a cell.

karyogram an alternative name for **idiogram**.

karyoid an alternative name for **nucleoid** (def. 1).

karyokinesis 1 an alternative name for **mitosis**. **2** division of the cell nucleus during mitosis. Compare **cytokinesis**.

karyon or **caryon** the nucleus of a cell.

karyopherin an alternative name for **importin**.

karyophilic proteins soluble proteins that accumulate in the nucleus on microinjection into the cytoplasm of amphibian oocytes. They are not bound to chromatin or other nuclear structures. They include **nucleoplasm** and the acidic nuclear proteins N1 to N4 of the *Xenopus* oocyte nucleus.

karyosome a compartment, located on the nucleolus of some plant species, that may support the rRNA genes as they extend from the nucleolar organizer region.

karyotype the visual appearance of the set of chromosomes of a typical somatic eukaryotic cell of a given species, individual, or cell strain. It is expressed in terms of chromosomal sizes, shapes, and number. —**karyotypic** *adj.*

kasugamine 2,4-diamino-2,3,4,6-tetra-deoxy-D-*arabino*-hexose; a component of **kasugamycin** and other antibiotics.

kasugamycin an aminoglycoside antibiotic produced by a strain of *Streptomyces kasugaensis* and containing **kasugamine**. It interacts stoichiometrically with the 30S ribosomal subunit, preventing initiation of protein biosynthesis in prokaryotes; it also blocks translation in fungal systems.

kat *symbol* for katal.

katabolism a variant spelling of **catabolism**. —**katabolic** *adj.*

katalcalin a 21-residue peptide derived from the protein precursor of calcitonin, in which it flanks calcitonin on the C-terminal side. It is potent in lowering plasma calcium levels. It is present in normal plasma in concentrations equimolar with calcitonin, and is released rapidly by calcium infusion.

katal *symbol*: kat; a derived coherent unit for expression of enzyme activities, defined as that **catalytic activity** of an enzyme that will raise the rate of conversion of a specified chemical reaction by one mole per second in a specified assay system. There are several important points regarding usage. (1) This definition supersedes a version expressed in terms of the intensive quantity 'rate of reaction' rather than the extensive quantity 'rate of conversion', as well as earlier versions in which catalytic activity was identified with the overall rate of reaction (including the spontaneous rate) rather than with the increase in rate. (2) The katal was adopted as a derived SI unit in 1999. (3) The katal is not used to express rates of conversion themselves (for which the unit is mol s^{-1}). (4) The katal is independent of assay conditions (although the measured catalytic activity of a given system depends on assay conditions). (5) Compare **enzyme unit**; 1 kat $\approx 6 \times 10^7$ U; 1 U ≈ 16.7 nkat).

katanin a microtubule-stimulated ATPase that severs and disassembles microtubules to tubulin dimers.

Kat.f. an obsolete unit for expressing the specific activity of catalase preparations, originally defined as the rate constant for the catalyzed reaction under certain conditions divided by the number of grams of enzyme in the total test volume. The rate constant is calculated from the standard equation for a unimolecular reaction using decadic logarithms and is expressed per minute. Later (apparently unintended) variations of this definition sometimes were used. [From the German *Katalasefähigkeit*, catalase capability.]

katharometer an apparatus used to determine the composition of a gas mixture by measuring its thermal conductivity.

kathode a variant spelling of **cathode**. —**kathodic** *adj.*

kation a variant spelling of **cation**.

KATP *abbr.* for ATP-dependent K^+ channel; *other name*: Kir 6.2; a K^+ inward rectifier channel of pancreatic B cells that is regulated by the ATP-binding sulfonylurea receptor.

Kauffmann-White scheme a classification scheme for the many serotypes of the bacterial genus *Salmonella*, defined in terms of their somatic (surface) antigens and, where appropriate, their capsular and flagellar antigens.

Kautsky effect the characteristic changes with time in the fluorescence emission of chlorophyll *a* that occur when dark-adapted cells or isolated chloroplasts are illuminated. The changes may be distinguished into a fast change lasting only a few seconds, and a slower change lasting a few minutes. [After Hans Kautsky (1891–1966).]

kayser a unit of **wave number** expressed as the number of wavelengths of electromagnetic radiation in 1 cm.

Kazal inhibitor an electrophoretically heterogeneous proteinaceous trypsin inhibitor and anticoagulant found in the pancreas and in pancreatic juice of a number of mammalian species. Compare **pancreatic trypsin inhibitor**. [After Louis Anthony Kazal (1912–), US physiologist.]

kb *symbol* for kilobase.

K capture see **electron capture**.

K cell 1 an immunocytochemically distinguishable, granule-containing cell, found in the duodenum and jejunum, that produces **glucose-dependent insulinotropic peptide**. **2** or **killer cell** a type of large granular mononuclear lymphocyte that can kill target cells sensitized with antibody. The K cells engage the antibody via their **Fc receptors**. They are probably identical with natural killer (NK) cells.

K chromophore any **chromophore** that gives rise to high-intensity absorption bands due to π - π conjugation. Compare **R chromophore**.

KCNE1 the gene at 21q22.1-q22.2 for a cardiac K channel β subunit.

It encodes minK, a protein of 129 amino acids, including one transmembrane segment. Numerous loss-of-function mutations are associated with the **long QT syndrome**. See also **KVLQT1**.

KCNQ *abbr.* for voltage-gated K^+ channel.

kDa *symbol* for kilodalton.

KDEL a tetrapeptide sequence (in the single-letter amino-acid code) at the C terminus of proteins that are to be retained in the endoplasmic reticulum (ER). An equivalent sequence is HDEL, especially in plants. KDEL binds the **KDEL receptor**, and retention is thought to be mediated by continual retrieval from a post-ER compartment. See also **luminal proteins**.

KDEL receptor a transmembrane protein of the endoplasmic reticulum that binds the **KDEL sequence**, which constitutes the C terminus of proteins destined to be retained in the endoplasmic reticulum. Such receptors are seven-transmembrane-helix proteins. An equivalent receptor in yeast for the HDEL sequence is a product of the gene *ERD2*.

KDO *abbr.* for ketodeoxyoctanoate.

ke- *abbr.* for *keto-*.

Kearns-Sayre syndrome (*abbr.*: KSS) or **chronic external ophthalmoplegia** (*abbr.*: CPEO) a mitochondrial disease of humans in which ptosis and paralysis of the external eye muscles may be accompanied by myopathy. It is frequently due to a large deletion (5 kbp) in mitochondrial DNA (mtDNA), and less commonly to point mutations in mtDNA for isoleucyl-, asparaginy-, or leucyl-tRNA. [After Thomas Kearns (1922–) and George Pomeroy Sayre (1911–), US ophthalmologists.]

KEGG *abbr.* for Kyoto Encyclopedia of Genes and Genomes; see **pathway database**.

Keilin-Hartree heart-muscle preparation a preparation of sub-mitochondrial particles from bovine heart muscle that is capable of catalysing the reoxidation by dioxygen of NADH and succinate. [After D. Keilin (1887–1963) and E. F. Hartree (1910–94).]

Kell system a blood-group system whose antigenic determinant is part of an erythrocyte membrane glycoprotein of 93 kDa that has an extracellular C-terminal domain with 15 cysteine residues, an N-terminal cytoplasmic domain, and a zinc binding site of the type found in neutral endopeptidases.

kelvin *symbol*: K; the SI base unit of thermodynamic temperature, defined as the fraction $1/273.16$ of the thermodynamic temperature of the triple point of water. The symbol K is used both for thermodynamic temperature and for thermodynamic temperature interval, and supersedes $^{\circ}\text{K}$ (degree Kelvin). [After William Thomson, Lord Kelvin (1824–1907), British mathematician, physicist, and inventor, who first defined the absolute scale of temperature.]

KEM1 the symbol of a gene of yeast that encodes a nuclease specific for G-quartets.

Kendall's compounds a series of naturally occurring steroids of the adrenal cortex and their metabolites; they were provisionally designated by US physiological chemist Edward Calvin Kendall (1886–1972), using letters of the alphabet, before elucidation of their structures. They are: Kendall's compound A, 11-dehydrocorticosterone; Kendall's compound B (Reichstein's substance H), corticosterone; Kendall's compound C (Reichstein's substance C), 5α -pregnane- $3\alpha,11\beta,17\alpha,21$ -tetrol-20-one; Kendall's compound D (Reichstein's substance A), 5α -pregnane- $3\beta,11\beta,17\alpha,20\beta,21$ -pentol; Kendall's compound E (Reichstein's substance Fa), cortisone; Kendall's compound F (Reichstein's substance M), cortisol; Kendall's compound G (Reichstein's substance D), 5α -pregnane- $3\beta,17\alpha,21$ -triol-11,20-dione; Kendall's compound H (Reichstein's substance N), 5α -pregnane- $3\beta,21$ -diol-11,20-dione; Kendall's desoxy compound B (Reichstein's substance Q), cortexone, 11-deoxycorticosterone.

Kennedy's disease *an alternative name for spinal and bulbar muscular dystrophy*.

kephalin *a variant spelling of cephalin*.

kerasin or **cerasin** a **cerebroside** in which the fatty acyl moiety is lignoceroyl.

keratan sulfate or (*formerly*) **keratosulfate** any member of a group of glycosaminoglycans with repeat units consisting of (β 1 \rightarrow 3)-linked D-galactopyranosyl-(β 1 \rightarrow 4)-N-acetyl-D-glucosamine 6-sul-

fate and containing variable amounts of fucose, sialic acid, and mannose units. In keratan sulfate I, isolated from cornea, the carbohydrate is attached to the polypeptide backbone through N-acetylglucosaminyl-asparaginy linkages, while in keratan sulfate II, isolated from cartilage and bone, the carbohydrate appears to be attached to the polypeptide backbone through N-acetylgalactosamine in O-glycosidic linkage to either serine or threonine residues. The keratan sulfates are often attached to the same polypeptide backbone as the chondroitin sulfates.

keratein the soluble product formed by reductive scission of disulfide cross-links in wool keratin on treatment with sulfhydryl compounds, such as thioglycolate.

keratin any member of a class of structural fibrous scleroproteins that occur in vertebrate skin and in various specialized epidermal structures, e.g. feathers, nails, hair, hooves, horns, and quills, as well as in the cytoskeleton. They are classified into **hard keratins**, specific to hair, nails, and feathers, and **cytokeratins**, which form part of the cell cytoskeleton. The hard keratins are typically sulfur-rich proteins cross-linked by disulfide bonds, having M_r in the region of 6000–20 000; the cytokeratins are larger (40 000–56 000) low-sulfur proteins. The hard keratins of mammals are largely α helical (α keratins), whereas those of birds and reptiles are largely β -sheet (β keratins). However, α keratin can be converted to a β -sheet conformation by reduction and heating (as in hairdressing). Cytokeratins are intermediate-filament proteins (similar to other intermediate-filament proteins), and are of two types: I (acidic) and II (neutral to basic) (40–55 and 56–70 kDa respectively); these form microfibrillar filaments in epithelial cells. Cytokeratin is composed of complexes formed by the aggregation of at least one of each type.

keratinization or **keratinisation** 1 the process by which epidermal cells synthesize keratin. 2 the elaboration of structures containing keratin, especially in skin. —**keratinize** or **keratinise** *vb*.

keratinocyte or **keratocyte** any epidermal cell that produces keratin.

keratohyalin a material seen in microscopic sections in granular cells of the skin. It is thought to consist mainly of **filaggrin**.

keratosulfate *a former name for keratan sulfate*.

kernicterus an encephalopathy associated with degeneration and yellow pigmentation of basal ganglia and other nerve cells in the spinal cord and brain, caused by the severe unconjugated bilirubinemia occurring in newborn infants and occasionally in older children with hereditary unconjugated hyperbilirubinemia.

kerosene or **kerosine** *an alternative name (esp. US) for paraffin* (def. 2).

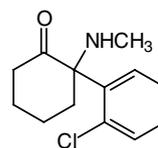

Kerr effect *an alternative name for electric birefringence*. [After John Kerr (1824–1907), Scottish physician.]

kestose 1 or (*sometimes*) **6-kestose** *O*- β -D-fructofuranosyl-(2 \rightarrow 6)-*O*- β -D-fructofuranosyl-(2 \rightarrow 1)- α -D-glucopyranose; a trisaccharide widely distributed in plants, especially in the bulbs and tubers of monocotyledons, and formed artificially when yeast invertase is incubated with a 50% solution of sucrose. The name is derived from the fact that it was discovered at the Tate and Lyle research laboratories, then at Keston, Kent, UK. 2 or **1-kestose** isokestose; inulobiosyl glucose; *O*- β -D-fructofuranosyl-(2 \rightarrow 1)-*O*- β -D-fructofuranosyl-(2 \rightarrow 1)- α -D-glucopyranose; an isomer and congener of 6-kestose. See also **neokestose**.

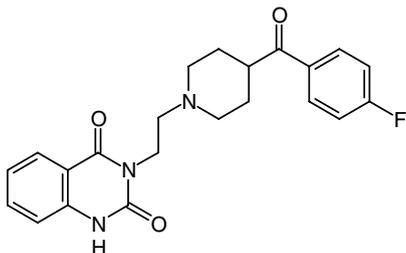

ket+ *a variant form of keto+* (sometimes before a vowel).

ketal *see acetal*.

ketamine (\pm)-2-(2-chlorophenyl)-2-(methylamino)cyclohexanone; a dissociative anesthetic with cataleptic and analgesic effects, possibly through acting as an N-methyl-D-aspartate (excitatory amino acid) receptor antagonist.

ketanserin 3-[2-[4-(4-fluorobenzoyl)-1-piperidiny]ethyl]-2,4[1*H*,3*H*]-quinazolinone; an antagonist to α_1 **adrenoceptors**, **H₁ histamine receptors**, and 5-HT₂ **5-hydroxytryptamine receptors**. A clinically effective hypotensive agent, it differentiates between 5-HT₁ and 5-HT₂ receptors with high specificity; within adrenoceptors and histamine receptors it is less specific.

ketene **1** ethenone; CH₂=C=O. **2** any substituted **ketene** (def. 1).

ketimine any **imine** that is an analogue of a ketone; the general structure is R₂C=NR' where R is any organyl group and R' may be any organyl group or H. *Compare* **aldimine**.

keto **1** carbonyl group, =CO, in any ketone. **2** describing a class of chemical compounds of the general formula R-CO-R' (where R, R' are not H). The term is often used to distinguish such compounds from isomeric compounds of another class, e.g. keto sugar. **3** a nonpreferred term, often still used, to denote the presence of a substituent in an organic compound of a double-bonded oxygen atom that is part of a ketonic structure. The recommended term is **oxo**.

keto+ **1** or (sometimes before a vowel) **ket+** *comb. form* indicating ketonic or derived from a ketone; e.g. ketal, ketoaldose, ketol. **2** or (sometimes before a vowel) **keton+** *comb. form* denoting of or pertaining to a **ketone body** or bodies; e.g. ketoacidosis, ketogenesis, ketonuria. **3** *prefix (in chemical nomenclature)* denoting a ketonic derivative of an indicated organic compound; **oxo** now recommended.

keto- *abbr.*: *ke-*; an optional prefix to the (semi)systematic name of a monosaccharide or monosaccharide derivative containing an uncyclized ketonic carbonyl group, used to stress its acyclic nature. *Compare* **aldehydo-**, **keto**, **keto+**.

keto acid any organic (carboxylic) acid containing a **keto** (def. 3) group; the recommended term is an **oxo acid**.

ketoacidosis a type of **acidosis** caused by enhanced production of **ketone bodies** by the ketogenic pathway. This excessive production lowers blood pH and promotes excretion of K⁺ and Na⁺ by the kidney, leading to cation depletion. It results most often from hormonal imbalance, especially insulin deficiency, when fatty acids are mobilized from adipose tissue, transported to the liver, and converted to ketone bodies. In humans, a plasma level of up to 8 mmol L⁻¹ is considered safe and may be beneficial, but in disease states levels may reach up to 20 mmol L⁻¹, contributing to life-threatening situations. *See* **ketogenesis**. —**ketoacidotic adj.**

2-keto adipic acid dehydrogenase EC 1.2.4.1; an enzyme of mitochondrial matrix that catalyses the reaction:

It is believed to be similar to the pyruvate dehydrogenase complex. Deficient activity gives rise to **2-keto adipic acidemia**.

2-keto adipic acidemia or (*esp. Brit.*) **2-keto adipic acidemia** a rare, largely benign condition in which 2-keto, 2-amino, and 2-hydroxy derivatives of adipic acid accumulate and are excreted in excessive amounts in urine. These metabolites are derived from catabolism of lysine, hydroxylysine, and tryptophan. The defect is considered to involve some component of the **2-keto adipic acid dehydrogenase** complex.

ketoaldonic acid any monosaccharide formally derived from an aldonic acid by oxidation of a secondary alcoholic hydroxyl group to an **oxo group**.

ketoaldose any monosaccharide containing both an aldehydic and a ketonic carbonyl group.

ketoconazole a complex derivative of imidazole, clinically useful as an antimycotic. It impairs ergosterol synthesis in fungal cell membranes, thereby increasing their permeability.

ketodeoxyoctanoate *abbr.*: KDO; 2-keto-3-deoxy-D-octanoate; 3-deoxy-D-manno-2-oxulosonate; an acid present in lipopolysaccharides of the outer membranes of certain Gram-negative bacteria.

keto-enol tautomerism a type of **tautomerism** in which the keto and enol forms of a compound are in equilibrium, the change corresponding to the migration of a hydron and a shift of bonding electrons. *Compare* **amino-imino tautomerism**.

ketofuranose any **ketose** in the **furanose** form.

ketogenesis the metabolic production of **ketone bodies**. The pathway starts with the formation of acetoacetyl-CoA (I) from two molecules of acetyl-CoA by **acetyl-CoA C-acetyltransferase** (EC 2.3.1.9); I then reacts with a further molecule of acetyl-CoA, in a reaction catalysed by **hydroxymethylglutaryl-CoA synthase**, to form (S)-3-hydroxy-3-methylglutaryl-CoA (II); II is then cleaved to acetoacetate and acetyl-CoA by **hydroxymethylglutaryl-CoA lyase**. These reactions occur in higher animals and are localized entirely in mitochondria; the liver is the main site of synthesis, but kidney, and possibly also small intestine, and adipose tissue may play a part in some situations.

ketogenic forming, or having the quality of being convertible into ketone bodies by metabolic processes.

α -ketoglutarate a *nonpreferred (though often used) name for* 2-oxoglutarate; 2-oxo-1,5-pentanedioate; a compound that has important roles in carbohydrate and amino-acid metabolism, especially in transamination reactions and as a component of the **tricarboxylic acid cycle**.

α -ketoglutaric dehydrogenase *see* **oxoglutarate dehydrogenase (lipoamide)**.

2-keto-L-gulonate or (*preferably*) **2-oxo-L-gulonate** L-xylo-2-hexulose-5-phosphate; a compound obtained from sorbitol and an important intermediate in the manufacture of **ascorbic acid**.

ketoheptose any **ketose** having a chain of seven carbon atoms in the molecule. Eight enantiomeric pairs of such compounds are possible.

ketohexokinase EC 2.7.1.3; *systematic name*: ATP:D-fructose 1-phosphotransferase; *other name*: hepatic fructokinase. An enzyme that catalyses the phosphorylation by ATP of D-fructose to D-fructose-1-phosphate with release of ADP. The enzyme occurs in cytosol of liver cells, in muscle, intestine, and renal cortex, and in bacteria. It also phosphorylates some other ketoses (e.g. 5-dehydro-D-fructose, D-sorbitose, D-tagatose). 'Fructokinase' is the recommended name for the enzyme EC 2.7.1.4, which forms D-fructose 6-phosphate (*see* **fructokinase**). In mammals, some fructose can be phosphorylated to fructose 6-phosphate by **hexokinase**. The rat liver enzyme consists of 299 amino acids. Two human isoforms are derived by alternative splicing from one gene. Inactivating mutations lead to hepatic fructokinase deficiency (also called essential fructosuria).

ketohexose any **ketose** having a chain of six atoms in the molecule. Four enantiomeric pairs of such compounds are possible, these being the D and L isomers of fructose, psicose, sorbose, and tagatose.

α -ketoisocaproate or (*preferably*) **α -oxoisocaproate** 2-methyl-2-oxopentanoate; an intermediate in the biosynthesis of L-leucine. *See* **leucine and valine biosynthesis**.

α -ketoisovalerate or (*preferably*) **α -oxoisovalerate** 3-methyl-2-oxobutanoate; an intermediate in the biosynthesis of L-leucine, L-valine, and pantothenic acid. *See* **leucine and valine biosynthesis**.

ketol **1** any organic compound that is both a ketone and an alcohol, especially an α -ketol (i.e. acyloin), one in which the two functions are adjacent. **2** the strongly reducing group, HO-CH₂-CO-, that is characteristic of an α -ketol. It is present, e.g., in ketoses and certain corticosteroids.

ketol-acid reductoisomerase EC 1.1.1.86; *systematic name*: (R)-2,3-dihydroxy-3-methylbutanoate:NADP⁺ oxidoreductase (isomerizing); *other names*: dihydroxyisovalerate dehydrogenase (isomerizing); acetoxyhydroxy-acid isomerase. An enzyme of chloroplasts that catalyses the reaction:

It is a component of the pathways for isoleucine and valine biosynthesis. The protein from *Spinacia oleracea* (spinach), for example, is a tetramer of similar but nonidentical chains.

ketol condensation the enzyme-catalysed formation of certain **ketols** (def. 1) by addition of an acyl moiety of one α -oxo acid to another α -oxo acid to form an α -hydroxy- β -oxo acid. It occurs, e.g., in the condensations catalysed by acetolactate synthase (EC 4.1.3.18); these involve either two molecules of pyruvate condensing to form α -acetolactate and CO_2 , or one molecule of pyruvate and one of α -oxobutyrate condensing to form α -aceto- α -hydroxybutyrate and CO_2 . The main products are biosynthetic precursors of valine and leucine, and of isoleucine, respectively.

ketolysis a term sometimes used to describe the oxidation, for energy production, of ketone bodies by extrahepatic tissues.

α -keto- β -methylvalerate or (preferably) **α -oxo- β -methylvalerate** 3-methyl-2-oxopentanoate; the biosynthetic precursor of, and catabolic product of, L-isoleucine.

keton+ a variant form of **keto+** (def. 2) (sometimes before a vowel).

ketone 1 any compound containing a carbonyl group, $>\text{C}=\text{O}$, joined to two carbon atoms. **2** the functional class name for any **ketone** (def. 1) that does not have a trivial name, e.g. ethyl methyl ketone.

ketone body any of the three substances: (1) acetoacetate, formed enzymically from acetyl-CoA; (2) D-3-hydroxybutyrate (β -hydroxybutyrate), formed by liver mitochondrial 3-hydroxybutyrate dehydrogenase (EC 1.1.1.30) from acetoacetate; or (3) acetone, formed by spontaneous decarboxylation of acetoacetate. Ketone bodies may accumulate in the body in starvation, diabetes mellitus, or in other defects of carbohydrate metabolism. They are formed in the post-absorptive state and during more prolonged fasting, and can be used as an alternative energy source to glucose, sparing glucose and thus indirectly muscle protein, since the carbon source for glucose synthesis under such conditions derives from muscle amino acids. Biosynthesis involves the formation of **hydroxymethylglutaryl-CoA**, which is cleaved to acetoacetate and acetyl-CoA by **hydroxymethylglutaryl-CoA lyase**; it occurs largely in the liver, but to a small extent also in kidney. Utilization of ketone bodies in peripheral tissues involves conversion by **3-oxo-acid CoA-transferase** of acetoacetate to acetoacetyl-CoA, which is then converted to two molecules of acetyl-CoA by **acetyl-CoA C-acetyltransferase**. 3-Hydroxybutyrate is classed as a ketone body because it exists in an equilibrium with acetoacetate that depends on the redox state in the liver mitochondria.

ketonemia or (esp. Brit.) **ketonaemia** an abnormally high concentration of **ketone bodies** in the blood.

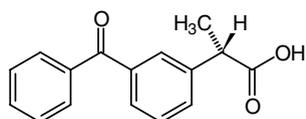

ketonic of, relating to, or having the properties of a **ketone** or a **keto** (def. 1) group.

ketonize or **ketonise** to convert into or become converted into a ketone. — **ketonization** or **ketonisation** *n.*

ketonuria a condition in which there is an abnormally large excretion of ketone bodies in the urine.

ketopentose any **ketose** having a chain of five carbon atoms in the molecule. Two enantiomeric pairs of such compounds are possible, these being the D and L isomers of ribulose and xylulose.

ketoprofen 2-(3-benzoylphenyl)propionic acid; a nonsteroidal anti-inflammatory agent; it inhibits prostaglandin-endoperoxide synthase (EC 1.14.99.1). See also **ibuprofen**.

(S)-ketoprofen

ketopyranose any **ketose** in the **pyranose** form.

ketose any monosaccharide in the acyclic form of which the actual or potential carbonyl group is nonterminal, i.e. ketonic. The sys-

tematic names and many of the trivial names of ketoses have the ending '+ulose'. The position of the (potential) carbonyl group is indicated by a prefixed locant (e.g. 3-ketose, 5-nonulose), which may be omitted from the name of a 2-ketose when no ambiguity can arise. The term is frequently modified by an infix indicating the number of carbon atoms in a chain in the molecule; thus **ketopentose**, **ketotetrose**, etc. Compare **aldose**.

ketosis any clinical condition in which there are abnormally high concentrations of **ketone bodies** in the tissues. The condition is usually accompanied by acidosis. See also **ketogenesis**. — **ketotic** *adj.*

ketosteroid a former name for **oxosteroid**.

keto sugar a common name for any **ketose**.

ketotetrose either of two **ketoses** having a chain of four carbon atoms in the molecule and known as dihydroxyacetone, or **glycero-tetrol**.

β -ketothiolase see **acetyl-CoA C-acyltransferase**.

ketotriose the single achiral **ketose** having a chain of three carbon atoms in the molecule and known as dihydroxyacetone, or **glycerone**.

ketin a 500–700 kDa protein of *Drosophila* muscle. Its N-terminal region lies in the Z disk and binds α -actinin. It contains Ig-like regions through which it binds to the thin filaments.

kex2 a structural gene for pre-pro- α mating type polypeptide in *Saccharomyces cerevisiae*. It gives rise to the designation Kex2 site, a cleavage site (Arg-|Arg or Lys-|Arg) for **kexin** in the processing of the mating polypeptide and several extracellular fungal proteins.

kexin EC 3.4.21.61; *other names*: yeast Kex2 protease; proteinase YSCF; prohormone-processing endoprotease; paired-basic endopeptidase. An enzyme that catalyses the cleavage of Lys-Arg-|Xaa and Arg-Arg-|Xaa bonds to process yeast α -factor pheromone and killer toxin precursors. The human enzyme with the same specificity (and EC number) is neuroendocrine convertase 1. See also **furin**, **kex2**, **proopiomelanocortin**.

keyhole limpet hemocyanin or (esp. Brit.) **keyhole limpet haemocyanin** *abbr.*: KLH; a respiratory protein from *Megathura crenulata* that elicits a strong T-cell immune response. It is frequently used as a carrier protein to which peptides or other haptens are coupled in order to induce an immune response when used as an immunogen.

kg *symbol* for kilogram.

KH domain *abbr.* for ribonucleoprotein K homology domain; a peptide sequence (40–60 amino acids) present in proteins believed to bind RNA. It consists of several invariant hydrophobic regions (containing Ile, Leu, Met, and Gly) and is highly conserved in the three proteins encoded by *FMRI* gene family members, each of which contains two KH domains. The protein **vigilin**, found in domestic fowl, contains 14 KH domains.

KHF *abbr.* for killer cell helper factor (i.e. **interleukin 2**).

kicksorter a multichannel pulse-height analyser, especially one used to distinguish between radioisotopes by sorting them according to the energies (i.e. 'kicks') of their emitted radiations.

kidney either of a pair of organs of vertebrates concerned with osmoregulation and the elimination of nitrogenous waste products. Kidneys of different species vary in structure according to the animal's mode of life, but their basic design and function is the same. Each kidney is enclosed in a capsule and is made up of an outer cortex and an inner medulla, and contains numerous **nephrons** and their associated blood supply. The nephrons filter constituents from the blood to form urine, which is discharged from the kidney via the ureter.

kieselguhr an alternative name for **diatomaceous earth**.

kifensine an alkaloid produced by the actinomycete *Kitasatospora kifumense* that inhibits **ER α -mannosidase I**.

killed vaccine any suspension of killed (or otherwise inactivated) microorganisms or virus used as an antigen to produce immunity.

killer cell any cell that is cytotoxic to *in vitro* cell cultures, e.g. killer T-lymphocytes and macrophages. Antibody-dependent cell-mediated cytotoxicity may be displayed by a number of cell types, e.g. by human monocytes or interferon-activated neutrophils, which can kill antibody-coated tumour cells, and by **NK cells**, which kill hybridoma cells through the NK cell Fc γ R/II receptor. See also **K cell**.

killer-cell helper factor *abbr.*: KHF; an alternative name for **interleukin 2**.

killer factor an RNA molecule responsible for the lethal property of killer strains of yeast.

killer strain any strain of cells that is able to kill sensitive cells of the same species, e.g. some strains of yeast and *Paramecium*. See also **kappa particle**, **killer factor**.

killer T-lymphocyte any T lymphocyte that is able to kill target cells. Killer T-lymphocytes are produced in response to viral infection or an allogeneic tissue graft, and are specifically cytotoxic to host cells infected with virus or to grafted cells carrying the major histocompatibility antigens of the donor, respectively.

kilo- *symbol:* k; an SI prefix denoting 10^3 times.

kilobase *symbol:* kb; a unit of length of a polynucleotide equal either to 1000 base residues in a single-stranded polynucleotide or to 1000 base pairs in a double-stranded polynucleotide.

kilocalorie or **kilogram calorie** or (*esp. in nutrition*) **Calorie** a non-SI unit of heat or energy equal to 10^3 cal_{IT}. See **calorie**.

kilodalton *symbol:* kDa; a unit of molecular mass equal to 10^3 daltons.

kilogram *symbol:* kg; the SI base unit of mass, and also the fundamental unit of mass in the metric system; it is equal to the mass of the International Prototype of the Kilogram, a cylinder of 90% platinum, 10% iridium, which is kept at the BIPM. It is the only base SI unit that is still defined in terms of an artifact.

kilogram calorie an alternative name for **kilocalorie**.

kinase any phosphotransferase enzyme that transfers a phosphate group, usually from ATP. Kinases are divided into EC sub-classes according to the nature of the phosphate-accepting group: EC 2.7.1 – phosphotransferases with an alcohol group as acceptor; EC 2.7.2 – phosphotransferases with a carboxyl group as acceptor; EC 2.7.3 – phosphotransferases with a nitrogenous group as acceptor; EC 2.7.4 – phosphotransferases with a phosphate group as acceptor. The name is also used for enzymes that transfer a phosphate group from other nucleoside triphosphates. Compare **dikinase**, **pyrophosphokinase**, **thiokinase**.

+**kinase** suffix (*in the trivial name of an enzyme*) 1 designating a kinase or, by extension in certain instances, one that transfers some other inorganic oxo-acid group, e.g. **sulfokinase**. 2 designating an enzyme that activates a zymogen by proteolysis, e.g. **enterokinase**, **streptokinase**, **thrombokinese**.

kinasing a jargon term for the act or process of labelling the 5' end of a nucleic-acid molecule or fragment with phosphorus-32 by reaction with adenosine 5'-[α - 32 P]triphosphate and the enzyme T4 polynucleotide kinase. This is a step in the **chemical cleavage method** for sequencing DNA and RNA.

kinectin a kinesin-binding protein (1356 amino acids) of endoplasmic reticulum and various other organelles. It contains an N-terminal transmembrane segment and an extensive region for coiled-coil formation in the C-terminal region. Its central region binds RhoGTPase.

kinematic viscosity *symbol:* ν ; the dynamic viscosity, η , of a fluid divided by its density, ρ , i.e. $\nu = \eta/\rho$.

kinesin microtubular motor protein, composed of two heavy chains and several light chains, that uses the energy of ATP hydrolysis (ATPase activity in the head of the heavy chain) to move along microtubules, mostly to the plus end, but in some cases to the minus end (e.g., in *Drosophila*). Kinesins are involved in organelle transport, and in mitosis and meiosis. See also **dynein**.

kinesin-binding protein an alternative name for JNK-interacting protein. See **JIP**.

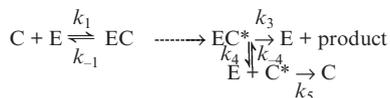

kinetensin or **neurotensin-related peptide** (*abbr.:* NRP) the nonapeptide Ile-Ala-Arg-Arg-His-Pro-Tyr-Phe-Leu; it has **neurotensin**-like immunoreactivity, and is isolated from human, bovine, and canine plasma.

kinetic 1 of or relating to the motions of material bodies and the forces and energies associated therewith; of or relating to motion. 2 of or relating to the rate(s) of change of physical or chemical systems. 3 of or relating to **kinetics**.

kinetic energy *symbol:* E_k or T or K ; the energy possessed by a material body by virtue of its motion, determined by the work necessary to bring it to rest.

kinetic proofreading a suggested mechanism of twice using the same Michaelis kinetic ability of an enzyme system to distinguish

between two substrates C and D. The essential features of the mechanism are contained in the following reaction scheme, shown for substrate C, but identical in form if substrate C is replaced by D.

The second step is enzymically coupled to an energy source, typically the hydrolysis of a nucleoside triphosphate, and is strongly enough driven to be essentially irreversible. EC^* , a high-energy intermediate, may either react to give free enzyme plus product or diffuse into the solution where it decomposes to free enzyme plus the nonproduct C^* , which can further decompose to C. According to kinetic proofreading, the incorrect intermediate, ED^* , diffuses into the solution and decomposes faster than it reacts to give the wrong product, i.e. for ED^* $k_3 \ll k_{-4}$, while for EC^* $k_3 > k_{-4}$. In this way, the better binding of C is used twice, once in the formation of EC and again in the binding of the intermediate EC^* . If the discrimination in the formation of the initial complex is f , a second factor of f^2 may theoretically be attained, giving a total discrimination of f^2 .

Kinetics 1 the branch of chemistry concerned with studying rates of chemical reactions. 2 the branch of mechanics concerned with the effects of forces on the motions of material bodies.

kinetin 6-furfurylaminopurine; N^6 -furfuryladenine; an artefactual compound formed by autoclaving DNA. It exhibits **cytokinin** activity in plants and was originally thought to be a naturally occurring substance. Compare **Kinetin**.

Kinetin a proprietary name for **hyaluronidase**. Compare **kinetin**.

kinetochore a specialized assembly of proteins that bind to the **centromere** and also attach to **microtubules** growing out from **centrosomes** during mitosis. They are involved in the separation of chromosomes into the daughter cells. They are composed of **centromere-binding proteins**.

kinetochore microtubule see **mitotic spindle**, **prometaphase**.

kinetoplast a DNA-rich organelle located within an expanded region of a mitochondrion lying close to the **basal body** in members of the order **Kinetoplastida**. The kinetoplast is self-replicating and divides before the nucleus in cell division.

Kinetoplastida an order of protozoans whose members are characterized by the presence of a **kinetoplast** in the mitochondrion. It includes the genera *Trypanosoma*, *Leishmania*, and *Crithidia*.

kinetosome an alternative name for **basal body**.

King-Altman method a general method for obtaining steady-state expressions for enzymic mechanisms with n enzyme-containing intermediates $EX_1 \dots EX_n$. First, a simple geometrical pattern describing the mechanism is drawn. Second, all possible patterns, consisting of $(n - 1)$ lines, that interconnect the possible enzyme forms are drawn; closed loops are forbidden. In general there will be $m!/(n - 1)!(m - n + 1)!$ patterns, where m is the number of interconversion steps. Third, n expressions for $(d[EX_i]/dt/[E_{tot}]) = 0$ in terms of the rate constants are set out and solved by determinant methods, using the fact that

$$\sum_{i=1}^n ([EX_i]/[E_{tot}]) = 1$$

where $[E_{tot}]$ is the total enzyme concentration. [After E. L. King and C. Altman, who described it in 1956.]

Kingdom the highest level of taxonomic classification. All organisms fall into one of three currently accepted kingdoms, each of which has unique and unifying characteristics: eukaryotes, prokaryotes, and archaea.

kinin 1 or **kinin-hormone** any member of a varied group of linear polypeptides that constitute a class of so-called tissue or local hormones. Each is locally released from diffuse stores in the body, not having specialized glands of secretion, and is rapidly inactivated at the site of release. Among the most important are **angiotensins**, **bradykinin**, **substance P**, **colostrokinin**, **urinary kinins**, and **secretin**. 2 **kinin-9** an alternative name (*sometimes*) for **bradykinin**. 3 **kinin-10** an alternative name (*sometimes*) for **kallidin** (lysylbradykinin). See **bradykinin**. 4 an alternative name for **cytokinin**.

kininase any enzyme concerned in the natural breakdown of a **kinin** (def. 1). Included are kininase I (*or* lysine carboxypeptidase, EC 3.4.17.3), a carboxypeptidase circulating in plasma that inactivates bradykinin and possibly also kallidin, and kininase II (peptidyl-dipeptidase A, EC 3.4.15.1), *also known as* **angiotensin-converting enzyme**.

kininogen any inactive precursor of a **kinin** (def. 1).

kininogenin *an alternative name for* **kallikrein**.

kinked-helix model of duplex DNA a speculative model of the structure of double-stranded DNA in chromatin, proposed in 1975 by British molecular biologists Francis Crick (1916–2004) and Aaron Klug (1926–) to account for the high degree of folding of the DNA (to about one seventh of its length). In this model, based on the B form of duplex DNA, all the base pairs of the double helix remain intact but a sharp turn, or kink, of 95–100° occurs every 20 base pairs along the duplex. At this point one base pair has become unstacked from an adjacent pair through change of the conformation of the deoxyfuranose ring of a nucleotide residue from one of its possible staggered conformations to another. It was suggested that a kink might render several base pairs more easily available for specific interaction with a protein, and that a similar type of folding might occur in double-stranded DNA in other situations, especially when closely associated with protein.

kinomere *an alternative term for* **centromere**.

Kirkwood–Riseman theory of hydrodynamic properties of complex structures a theory providing an approximate method for computing the friction of a structure made up of identical subunits. A linear or coiled polymer is approximated as a string of beads, each with identical hydrodynamic properties, while an oligomeric protein is modelled as a cluster of identical subunits each with identical hydrodynamic properties.

Kirkwood theory of dielectric polarization of polar liquids an extension of the Onsager theory in which the dielectric constant of the central molecule and its first shell of neighbours is considered to differ from its macroscopic value. [After John Gamble Kirkwood (1907–59).]

Kirkwood theory of ion–dipole interactions a model in which the electrical contribution to the chemical potential of an ion having an arbitrary charge distribution is calculated with the aid of the Debye–Hückel theory and in which the Born relation between the free energy of solvation of a spherical ion and the dielectric constant of the solvent is generalized to include ions of arbitrary charge distribution.

Kirkwood–Westheimer theory of electrostatic effects on acid dissociation constants an extension and amplification of the Bjerrum theory of the influence of substituents on acid dissociation constants, the molecules and ions entering into ionization equilibria being treated as cavities of low dielectric constant. [After John Gamble Kirkwood (1907–59) and Frank Henry Westheimer (1912–), US biochemist.]

KIRs killer cell immunoglobulin-like receptors; receptors that are found on **NK cells**, and some $\gamma\delta$ and $\alpha\beta$ **T-cells**. They recognize **MHC class I** molecules and, like the C-type **lectin** receptors also found in these cells, can either inhibit or activate the killer cells. If **ITIM** sequences are present in their cytoplasmic domain they are inhibitory. **KIRs** lacking **ITIMs** can associate with **ITAM**-containing adaptor molecules in which case they can activate the killer cell.

kirromycin *or* **mocimycin** an antibacterial antibiotic isolated from *Streptomyces collinus* and others. It specifically interacts with **elongation factor EF-Tu** (*see* **EF-T**) and prevents the release of EF-Tu from the bacterial ribosome after GTP hydrolysis. In the absence of ribosomes, the antibiotic induces an EF-Tu-dependent hydrolysis of GTP.

kis- *see* **multiplying prefix**.

kistrin a protein isolated from the venom of the Malayan pit viper, *Agkistrodon rhodostoma*. It contains the **RGD** sequence, and binds to a platelet adhesion site. It is a potent platelet aggregation inhibitor and antagonist of a family of glycoproteins that mediate aggregation. *For example, see* **disintegrin**.

kit a commercially available collection of biochemical reagents and apparatus to carry out a procedure, such as an assay.

KIT a family of genes encoding plasma membrane class III receptor

tyrosine kinases. The viral gene, *v-kit*, is the oncogene of the Hardy–Zuckerman 4 strain of acutely transforming feline sarcoma virus. The product of the protooncogene *c-kit* has five immunoglobulin-like loops in the extracellular domain; the cytoplasmic region contains a tyrosine kinase domain with an insert region, and is myristoylated. Interaction with its ligand, steel factor (*see* **stem cell factor**), brings about dimerization, leading to enhanced autophosphorylation and binding of phosphatidylinositol 3-kinase and phospholipase C γ . Kit and its ligand are highly expressed in small-cell lung cancer and a significant proportion of testicular germ cell tumours.

Kjeldahl flask a small pear-shaped glass flask with a long neck, as used in the **Kjeldahl method**.

Kjeldahl method a method for the determination of the total nitrogen in an organic compound or mixture of compounds. The sample, in a **Kjeldahl flask**, is digested in hot, concentrated sulfuric acid with a catalyst, usually one containing mercury, copper, or selenium; the nitrogen in the sample is thereby converted to ammonium hydrogen sulfate. The ammonium formed may be estimated by neutralization and steam distillation of the resultant ammonia into a known amount of acid, the residual acid being determined by titration, or it may be estimated by **nesslerization** or with an ammonium electrode. [After Johan Kjeldahl (1849–1900), Danish chemist.]

Kleinschmidt technique a technique for preparing monolayers of DNA for electron microscopy in which the DNA molecules are bound to a film of denatured basic protein, e.g. cytochrome *c*, on the surface of an aqueous solution. The DNA molecules are consequently brought from a three-dimensional conformation to a two-dimensional one by adsorption to the protein layer. The DNA–protein complex is then transferred to a solid surface, e.g. an electron microscope grid or collodion film, dried, and contrasted with heavy metals by shadowing or staining. The tendency of **ssDNA** to fold back on itself with the formation of intramolecular base pairs can be overcome by using formamide (which denatures short base-paired regions) or by replacing cytochrome *c* with DNA-unwinding proteins, which have high affinity for ssDNA. The method may also be applied to RNA. [After Albrecht K. Kleinschmidt (1916–), German microbiologist.]

Klenow enzyme *or* **Klenow fragment** the larger (75 kDa) of the two fragments formed by the treatment of *Escherichia coli* DNA polymerase I with subtilisin in the presence of DNA. It retains the polymerase activity and the single-strand-specific 3'→5' exonuclease activities but lacks the 5'→3' exonuclease activity of DNA polymerase I. It is useful in sequencing single-stranded DNA. [After Hans Klenow (1923–), Danish biochemist.]

KLF *abbr. for* Krüppel-like factor.

KLH *abbr. for* keyhole limpet hemocyanin.

Klinefelter syndrome a genetic condition in which males have an extra X chromosome (XXY). It occurs as frequently as 1–2 per 1000 male births, and the chief sign is infertility caused by androgen deficiency and absence of sperm. Stature is also often affected, with long limbs and above-average height, and secondary sexual characteristics can be underdeveloped. The term **XXY male** is preferred because many are otherwise normal individuals who do not have the syndrome as originally described. [After Harry F. Klinefelter (1912–), US physician.]

Klotz plot *a name sometimes given to* a plot of the reciprocal form of an equation describing ligand binding at multiple independent sites on, e.g., a macromolecule. It has the form:

$$1/\bar{v} = (1/nk)(1/[A]) + 1/n,$$

where \bar{v} is the average number of ligand molecules bound per molecule of the macromolecule, n is the number of binding sites per macromolecule, $[A]$ is the molar concentration of free ligand molecules, and k is the intrinsic association constant. If the equation correctly describes the equilibria involved, a plot of $1/\bar{v}$ versus $1/[A]$ gives a straight line of slope $(1/nk)$ and with an intercept on the $1/\bar{v}$ axis of $1/n$ and on the $1/[A]$ axis of $-1/k$. [After Irving Myron Klotz (1916–), US biochemist.]

k-means clustering an algorithm for clustering data that allows generation of user-specified numbers of clusters from a given data

set based on distance metrics for similarity. The method is dependent both on the specified value of k , which determines the number of clusters that are created, and on the distance measure employed. It is widely used in the analysis of microarray data.

KMEF group *abbr.* for keratin-myosin-epidermin-fibrinogen group; a group of proteins that have in common an α -type X-ray diffraction pattern. Some of these may show a β -type pattern in some conditions. Silk fibroin, which normally occurs with a β structure, is often included in the KMEF group.

knallgas bacteria or **hydrogen bacteria** any of a number of bacterial species that can obtain energy from the **knallgas reaction**, i.e. the oxidation of dihydrogen to water by dioxygen. They include some *Alcaligenes* and *Pseudomonas* spp. and *Paracoccus denitrificans*. [From the German, *Knallgas*, an explosive mixture of hydrogen and oxygen.]

knallgas reaction the energy-yielding direct oxidation of dihydrogen by dioxygen occurring in certain bacteria (*see* **knallgas bacteria**). The reaction is:

knockdown in gene expression the experimental reduction in the amount of a specific gene product. It is usually achieved by the use of siRNA to decrease the abundance of its mRNA or inhibit its translation. *Compare* **knockout**.

knockin denoting an animal in which a gene function has been introduced by genetic engineering techniques. [Opposite to 'knock-out'.]

knockout indicating an animal in which function of a gene has been deleted by genetic engineering techniques.

Knoop's hypothesis the hypothesis that fatty acids are metabolically oxidized by the successive removal of two-carbon fragments as acetic acid. *See also* **beta oxidation**. [After Franz Knoop (1875–1946), German physiologist and biochemist.]

Knop solution an aqueous solution containing the major inorganic constituents required for the growth of cells of higher plants, namely calcium nitrate, potassium nitrate, magnesium sulfate, potassium dihydrogen phosphate, and potassium chloride. [After J. A. L. W. Knop (1817–1901), German chemist.]

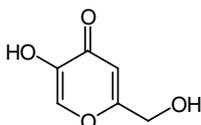

Knox plot (*in high-performance liquid chromatography*) a plot of relative separation efficiency versus flow rate, useful in determining the optimal conditions for a desired separation. [After John H. Knox.]

Knudson's hypothesis (two-hit hypothesis) the hypothesis, formulated in the early 1970s, that hereditary retinoblastoma results from the inheritance of one mutant copy of the *RB1* gene and mutation of the second normal allele during the life of the patient. Such a situation, in which somatic mutation occurs alongside one inherited mutant allele, is known as loss of heterozygosity (LOH). [After Alfred Knudson (1922–), US geneticist.]

Koch phenomenon a cell-mediated hypersensitivity reaction in which inflammation of guinea-pig skin, when injected with living or dead *Mycobacterium tuberculosis*, is very much greater in animals actively infected with the organism than in uninfected animals injected with dead organisms. [After (Heinrich Hermann) Robert Koch (1843–1910), German bacteriologist, who isolated the bacillus in 1882.]

kobjibiose the disaccharide 2-*O*- α -D-glucopyranosyl-D-glucopyranose.

kojic acid 5-hydroxy-2-(hydroxymethyl)-4*H*-pyran-4-one; a metabolite from *Aspergillus oryzae* and *A. terreus*. It can be obtained in large amounts and has some industrial application.

Kok effect the sharp difference in yield of photosynthesis above and below the compensation point. Below compensation, where respira-

tion can supply intermediates at a greater rate than the rate of photosynthesis, the yield is about twice as great as above compensation, where CO₂ has presumably to be drawn into the process. [After Bessel Kok (1918–81) Dutch-born US plant physiologist.]

Kornberg enzyme an alternative name for DNA polymerase I. *See* **DNA polymerase**. [After Arthur Kornberg (1918–), US biochemist.]

Korrigan cellulase a subunit of the **cellulose synthase** complex found in plasma membranes of plant cells. It cleaves off the glucan chain from celldextrin with release of the sitosterol β -glucoside primer and the glucan chain, which then forms the microfibrils of cellulose.

Korsakoff's psychosis *see* **Wernicke-Korsakoff syndrome**.

Koshland model *see* **induced-fit theory**.

Kozak sequence a consensus sequence (optimally CCA/GC-CAUGG) located around the **translation start site** and involved in its recognition by the ribosome.

KpnI a type 2 **restriction endonuclease**; recognition sequence: GGTA \uparrow C.

Kr symbol for krypton.

Krabbe's disease an alternative name for **galactosylceramide lipidosi**. [After Knudd Haraldsen Krabbe (1885–1961), Danish physician.]

KRB *abbr.* for Krebs Ringer bicarbonate; *see* **Krebs mammalian Ringer**.

Krebs-Cohen dismutation The anaerobic reaction summarized as:

It has been shown to occur in pigeon heart and breast muscle, rat and guinea-pig renal cortex, and rat-liver mitochondria. It is the sum of two reactions:

and

[After (Sir) Hans Adolf Krebs (1900–81), German-born British biochemist, and Philip Pacy Cohen (1908–93), US biochemist.]

Krebs cycle an alternative name (*sometimes*) for **1 tricarboxylic-acid cycle**. **2 ornithine-urea cycle**.

Krebs-Henseleit cycle an alternative name for the **ornithine-urea cycle**. [After (Sir) Hans Adolf Krebs (1900–81), German-born British biochemist, and Kurt Henseleit (1908–73).]

Krebs-Henseleit Ringer bicarbonate *see* **Krebs mammalian Ringer**.

Krebs-Kornberg cycle an alternative name for **glyoxylate cycle**. [After (Sir) Hans Adolf Krebs (1900–81) and Hans Leo Kornberg (1928–), German-born British biochemists.]

Krebs mammalian Ringer any of several media devised for the suspension of mammalian tissues. In the first version (1932), **Krebs-Henseleit Ringer bicarbonate**, the buffer was bicarbonate-CO₂, while in the second (1933), **Krebs original Ringer phosphate**, it was phosphate. In improved versions (1950), often referred to respectively as **Krebs Ringer bicarbonate** (*abbr.*: KRB) and (calcium-free) **Krebs Ringer phosphate** (*abbr.*: KRP), a mixture of organic acids and glucose was substituted for part of the NaCl in the first two versions, to resemble as closely as possible the state of the tissues in the intact animal. Also, an additional medium, low in phosphate, bicarbonate, and CO₂, was devised. *See also* **Ringer's solution**.

Krebs' manometer fluid a solution containing 44 g NaBr, 0.3 g Triton X-100, and 0.3 g Evans' Blue in 1000 mL of water; $D = 1.033$. The standard pressure (760 mmHg) in mm of manometer fluid is 10 000. Other detergents may be substituted for the Triton X-100 in equivalent proportions.

K region a region in a carcinogenic polycyclic aromatic hydrocarbon molecule in which there is a carbon-carbon bond having ordinary double-bond rather than aromatic character and that takes part in addition reactions; e.g. the bond between atoms C-9 and C-10 in phenanthrene. It has been suggested that carcinogenicity in such molecules is determined by the existence in them of an active K region. *Compare* **L region**.

kringle a protein module of about 85 amino-acid residues that is

held in a characteristic 3-D conformation by three internal disulfide bridges. It is so-named because its 2-D representation resembles that of the kringle, a Scandinavian pastry of characteristic shape. It was first described in prothrombin, but has since been found in plasminogen and (both tissue-type and urokinase-type) plasminogen activators.

Kronig–Kramers transform any of a set of mathematical relations describing the response of a system to a perturbation such as light. These relations allow the calculation of optical rotary dispersion from circular dichroism (ellipticity) and vice versa, and describe the relationship between dispersion and absorption. [After R. de L. Kronig and Hendrik Anthony Kramers (1894–1952), Dutch physicist, who independently devised them in 1926 and 1927, respectively.]

KRP *abbr.* for Krebs Ringer phosphate; *see* **Krebs mammalian Ringer**.

Krüppel a protein involved in the segmentation of the embryo and in the differentiation of the malpighian tubules in insects (e.g., *Drosophila*). It is a nuclear, chromatin-associated protein, encoded by a **gap gene**, and is a member of a subfamily of C₂H₂-type zinc-finger proteins. Mutant *krüppel* larvae lack eight body segments. [From German *Krüppel*, cripple.]

Krüppel-like factor *abbr.*: KLF; any DNA-binding transcriptional regulator that is homologous to **Krüppel** protein of *Drosophila*. At least 15 human KLFs are recognized.

KS/hst a human oncogene, with no known viral counterpart, whose product is related to **fibroblast growth factor** and is expressed in **Kaposi's sarcoma**.

k(T) *symbol* for rate constant (alternative to *k*, used when distinction of a rate constant from the Boltzmann constant is necessary).

K-tup *an alternative term* for **K-tuple**.

K-tuple or **K-tup** the number of sequence characters that are considered as an indivisible unit (or word) by database search algorithms such as FastA.

Ku the dsDNA-binding component of **DNA-PK**.

Kunitz and Northrop inhibitor *see* **pancreatic trypsin inhibitor**.

Kunitz inhibitor the best known of the three **soybean trypsin inhibitors**. The term refers to any type of protease inhibitor that contains consensus sequences known as **Kunitz domains**. These include some serine protease inhibitors. Such domains have also been identified in some α -amyloid precursor protein isoforms.

Kunitz (tryptic) unit a measure of tryptic activity based on the extent to which trypsin-containing samples can digest casein under standard conditions, often used to determine the relative amounts of Kunitz and Bowman–Birk type trypsin inhibitors present in samples, comparison being made between tryptic activity and chymotryptic activity. Crystalline trypsin has an activity of 6 Kunitz units per mg.

Kupffer cell a type of nonmotile, mononuclear phagocytic cell. Such cells line the sinusoids of the liver. [After Karl Wilhelm von Kupffer (1829–1903), German anatomist.]

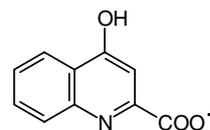

kuru a transmissible **spongiform encephalopathy** of humans, characterized by degeneration of the nervous system and found among the

Fore people of Papua New Guinea. It is a **prion** disease, transmitted through funerary practices thought to have involved endocannibalism. The brains of victims of this and **Gerstmann–Sträussler syndrome** contain so-called kuru plaques, which have been shown to stain positively with antibodies against prion protein in patients with Gerstmann–Sträussler syndrome. It has become extremely rare since cannibalism ceased in the late 1950s.

KVLQT1 the gene at 11q15.5 for a cardiac K voltage-gated channel α subunit. It encodes 676 amino acids, including six transmembrane segments and extensive intracellular N- and C-terminal domains. Numerous loss-of-function mutations are associated with the **long QT syndrome**. *See also* **KCNE1**.

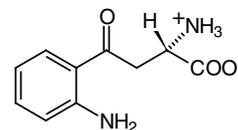

kwashiorkor a form of severe malnutrition of children occurring in tropical or near-tropical regions. It is generally believed to be caused by a dietary deficiency of protein, but not of other energy-producing foodstuffs. The condition commonly develops when, after prolonged breast feeding, the child is weaned onto a diet inadequate in protein. *Compare* **marasmus**.

kynurenate 4-hydroxyquinaldate; 4-hydroxy-2-quinoline carboxylate; the anion of kynurenic acid and an intermediate in the conversion of **kynurenine** to quinaldate.

kynureninase EC 3.7.1.3; *systematic name*: L-kynurenine hydroxylase; a pyridoxal-phosphate-containing enzyme that hydrolyses L-kynurenine to anthranilate and L-alanine. It also acts on 3'-hydroxy-kynurenine and some other (3-arylcaryl)alanines.

kynurenine 3-anthraniloylalanine; L-kynurenine is a metabolite on the degradative pathway of tryptophan, is found in the urine especially in pyridoxal (vitamin B₆) deficiency, and is an intermediate in the synthesis of nicotinic acid from tryptophan.

kyotorphin the analgesic dipeptide, L-Tyr-L-Arg, isolated from bovine brain; D-kyotorphin is L-Tyr-D-Arg.

l *symbol for 1 litre (alternative to L). 2 liquid.*
l *symbol for length (alternative to L).*
l- *prefix (in chemical nomenclature) denoting levorotatory; now obsolete, use (-); see **optical isomerism**.*
L *symbol for 1 litre (alternative to l). 2 a residue of the α -amino acid L-leucine (alternative to Leu). 3 an atom of hydrogen that may be one of either protium or deuterium. 4 linking number. 5 light chain (def. 1) (of an immunoglobulin).*
L *symbol for 1 Avogadro constant (alternative to N_A). 2 latent heat. 3 radiance.*
L- *a configurational prefix used in designating the absolute configuration of chiral compounds of certain classes; see **D/L convention**.*
La *symbol for lanthanum.*
label 1 *or (sometimes informally) tag any (radioactive or stable) isotope substituted in a proportion of the molecules of a particular compound so that the translocation and/or the chemical or biochemical transformation of the compound may be followed. See also **tracer**. 2 or (sometimes) marker an easily recognizable chemical group (which can be radioactive) attached to a molecule or incorporated within a structure. 3 to attach or apply such a label. The following particular uses of the terms label or labelled have individual entries (see also the list at **labelling**): **affinity label**, **electron-dense label**, **immunoassay**, **mixed labelled**, **multiply labelled**, **nonselectively labelled**, **photoaffinity label**, **radioactive label**, **selectively labelled**, **singly labelled**, **specifically labelled**, **spin label**, **uniformly labelled**.*
labelled compound *or (US, usually) labeled compound a compound bearing a label (def. 1, 2). An isotopically labelled compound is a compound in which one or more atoms of a proportion of the molecules have been replaced by a (radioactive or stable) isotope; i.e. it is a mixture of an isotopically unmodified compound with one or more analogous isotopically substituted compound(s). In some cases, the amount of isotopically unmodified compound may be small. This is particularly the case for ^2H compounds, when near 100% replacement is possible. See also **carrier-free**.*
labelling *or (US, usually) labeling 1 the attribute of being labelled. 2 the act or process of chemically introducing a label (def. 1, 2) into a compound either by substitution or by synthesis, or of incorporating such a label into a material or structure. The following particular uses of the term labelling have individual entries (see also the list at **label**): **conjugation labelling**, **double labelling**, **enzyme labelling**, **ferritin labelling**, **fluorescein labelling**, **generally labelled**, **hapten-sandwich labelling**, **iodine labelling**.*
labile 1 *describing a chemical compound that is prone to spontaneous change or decomposition; relatively unstable. 2 describing an atomic or molecular grouping in a chemical compound that usually readily dissociates from the compound; loosely attached. 3 describing a chemical bond that very easily ruptures or is ruptured. —lability *n*.*
labile factor *an alternative name for factor V; see **blood coagulation**.*
labile phosphate *the amount or proportion of any phosphate that is readily liberated from a phosphate-containing compound by hydrolysis in 1 M HCl at 100°C within 7–10 min (hence also sometimes known as **seven-minute phosphate** or **ten-minute phosphate**). These conditions were selected originally for estimating the two terminal phosphate groups of ATP. The following compounds are included in the group (percentage hydrolysis in parentheses): phosphocreatine (100), ATP (67), ADP (50), aldose 1-phosphate (100), pyrophosphate (100).*
labilize *or labilise to render labile (esp. def. 3). —labilization or labilisation, labilizer or labiliser *n*.*
lac *any of various resinous substances secreted by certain plants or insects, used in the manufacture of lacquers.*
lac *symbol for the genetic system of *Escherichia coli* that controls the organism's ability (lac^+) or inability (lac^-) to metabolize **lactose**. See also **lac operon**, **lac repressor**.*
laccase *any of a group of copper-protein enzymes (EC 1.10.3.2) of low specificity, that catalyse the oxidation of both *o*- and *p*-quinols*

by dioxygen to form the corresponding semiquinones and two molecules of water. They are so-called because such an enzyme was first found in the lac (or lacquer) tree (*Rhus verniciflua*); however, they are now known to be widely distributed in plants and fungi.

lacI *the structural gene for **lac repressor**, the repressor of the **lac operon**.*

lacI^a *a mutation in the promoter of the **lacI** gene of *E. coli* that results in increased transcription and higher levels of **lac repressor** within cells.*

lac operon *or lactose operon a genetic system, or operon, of *Escherichia coli* that controls the synthesis of the inducible enzyme β -D-galactosidase (see **galactosidase**). It is probably the most intensively studied group of *E. coli* genes. It consists of a linear sequence (5' end to 3' end of the coding strand) of two control sites, designated *p* and *o*, followed by three structural genes, designated *z*, *y*, and *a*; *p* is the promoter (concerned with RNA-polymerase binding), *o* is the operator (binding site for repressor), *z* is the gene for β -galactosidase, *y* is the gene for the **permease**, and *a* is the gene for thiogalactoside transacetylase (an enzyme of uncertain physiological function). Immediately preceding the *p* site is a regulatory gene designated *i* (concerned with synthesis of **lac repressor**).*

lac repressor *a protein encoded by the **lacI** gene, that controls the expression of structural genes coding for enzymes involved in lactose metabolism in the *Escherichia coli* genome; in the absence of inducer it binds with high affinity to the operator site of the **lac operon**. It is a homotetramer and specifically recognizes a 23 base-pair DNA sequence in the **lac** operator by means of its four N-terminal domains (headpieces), each of 51 amino-acid residues; each subunit also has one allosteric binding site for an inducer. The repressor is a typical **helix-turn-helix** protein and gives its name to a subfamily.*

lact+ *a variant form of **lacto+** (before a vowel).*

lactacin *any of a family of pore-forming peptidic toxins with approximately 75 + 65 amino acid residues, permitting passage of small solutes, including water. They are produced by *Lactobacillus johnsonii* and are classified in the TC system under number 1.A.26.*

lactadherin *a protein produced by smooth muscle cells of the aorta and the precursor of the polypeptide **medin**.*

lactalbumin 1 *the fraction of (normally cow's) milk proteins remaining after removal of casein. It consists principally of **beta-lactoglobulin** and α -lactalbumin. 2 α -lactalbumin a Ca^{2+} -binding protein that occurs as a minor constituent of milk of many mammals; its 123 amino-acid sequence is highly similar to that of lysozyme. It is a non-catalytic regulatory protein whose presence is required for **lactose synthase** to transfer a galactose residue from UDPgalactose to D-glucose; hence it is also known as B protein of lactose synthase. It causes the substrate for *N*-acetyllactosamine synthase to change from *N*-acetylglucosamine to glucose, to give lactose and UDP. Protein B had, therefore, been called a '**specifier**' protein. The genes for lysozyme and α lactalbumin arose evolutionarily from a common ancestral gene.*

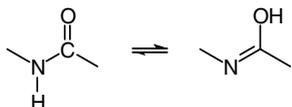

lactam *any intramolecular cyclic amide produced by the formal removal of a molecule of water between the amino and the carboxyl groups of an amino acid, other than an α -amino acid. A prefix (as in β -lactam) may be used to designate the position of the amino group in the parent compound. A lactam commonly exists in tautomeric equilibrium with its corresponding **lactim**.*

β -lactam antibiotic *any member of a class of natural or semisynthetic antibiotics whose characteristic feature is a strained, four-membered β -lactam ring (see **lactam**). They include the **penicillins** and many of the **cephalosporins**.*

β -lactamase *any member of a group of constitutive or inducible enzymes (EC 3.5.2.6); systematic name: β -lactamhydrolase. They are produced by certain strains of various bacterial species and can catalyse the hydrolysis of the **lactam** linkage in one or more β -lactam antibiotics, leaving a substituted β -amino acid; they thereby inactivate the antibiotic. The enzymes are of varying specificity, some*

acting more rapidly on penicillins (**penicillinases**), some more rapidly on cephalosporins (**cephalosporinases**); the latter were formerly classified separately as EC 3.5.2.8. The β -lactamases can be inhibited by various substances, such as **clavulanic acid**. There are several classes: class A (or type I) enzymes have seven motifs; class B (or type II) enzymes have a zinc cofactor. For example, the class A Men-1 from *Escherichia coli* has a broad spectrum of activity, hydrolysing penicillins and many cephalosporins.

lactam–lactim tautomerism a form of **tautomerism** occurring in lactam–lactim interconversion as a result of migration of a hydron between the nitrogen atom and the oxygen atom. It represents a special case of amide–imidol tautomerism.

lactase a trivial name for any β -D-galactosidase. Some lactases hydrolyse other glycosides, including α -L-arabinosides, β -D-fucosides, and β -D-glucosides.

lactase deficiency a condition of humans in which there is a congenital or acquired deficiency of lactase (i.e. β -galactosidase) in the mucosa of the small intestine leading to failure to digest lactose and to **lactose intolerance**. The condition is more common in healthy adolescents and adults, and its frequency varies considerably: it is more prevalent in native populations of Australia and Oceania, east and south-east Asia, tropical Africa, and the Americas (45–95%) than in those of central and northern European ancestry (<25%).

lactate 1 α -hydroxypropionate; 2-hydroxypropanoate; the anion, $\text{CH}_3\text{-CH(OH)-COO}^-$, derived from **lactic acid**. It occurs naturally as D(–)-lactate (i.e. (R)-2-hydroxypropanoate) and L(+)-lactate (i.e. (S)-2-hydroxypropanoate). L(+)-lactate is formed by anaerobic glycolysis in animal tissues, and DL-lactate is found in sour milk, molasses, and certain fruit juices. Bacterial **lactic-acid fermentations** produce either the D(–) or L(+) enantiomer or the racemate (DL) depending on the individual organism. 2 any salt or carboxylic ester of lactic acid. 3 to secrete milk; see **lactation**.

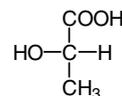

lactate dehydrogenase any enzyme that interconverts **lactate** and pyruvate. **L-lactate dehydrogenase** (EC 1.1.1.27; *abbr.*: LD or LDH) acts on L-lactate and NAD^+ . It occurs as homotetramers or heterotetramers of the heart muscle (H) and skeletal muscle (M) forms (the five isoenzymes are: LD_1 , H_4 ; LD_2 , H_3M ; LD_3 , H_2M_2 ; LD_4 , HM_3 ; and LD_5 , M_4). In clinical chemistry the assay of LD_1 (known also as α -hydroxybutyrate dehydrogenase or HBD) can be of use in diagnosing myocardial infarction, in which it peaks at 2–3 days after the infarct, and in hemolytic crisis of sickle-cell anemia, since this isoenzyme is the predominant form in cardiac muscle and red cells. **D-lactate dehydrogenase** (EC 1.1.1.28) acts on D-lactate and NAD^+ . **L-lactate dehydrogenase (cytochrome)** (EC 1.1.2.3) acts on L-lactate and ferricytochrome *c* and is a flavohemoprotein (FMN is coenzyme). **D-lactate dehydrogenase (cytochrome)** (EC 1.1.2.4) acts on D-lactate and ferricytochrome *c* and is a flavoprotein (FAD is coenzyme). **D-lactate dehydrogenase (cytochrome c-553)** (EC 1.1.2.5) acts on D-lactate and ferricytochrome *c*-553 and is present in *Desulfovibrio vulgaris*. These enzymes are very widely distributed.

lactation 1 the secretion of milk by the mammary gland. 2 a complete period of milk secretion from about the time of parturition to that of weaning. See also **lactate** (def. 3).

lactal 1 of, relating to, or resembling milk; milky. 2 (of lymph vessels) containing or conveying **chyle**. 3 any blind-ended lymph vessel that carries chyle from a villus of the small intestine to the thoracic duct.

lactal pertaining to, or derived from, milk.

lactic acid α -hydroxypropionic acid; 2-hydroxypropanoic acid; a reasonably strong acid ($\text{p}K_a = 3.86$ at 25°C). In biological systems it normally exists largely as its anion, **lactate** (def. 1). It is also useful as a preservative of foodstuffs.

lactic-acid bacterium any bacterium in which lactate is the main metabolic product. Such bacteria belong chiefly to the genera *Lactobacillus* and *Streptococcus*, and some are of commercial importance, e.g. in the manufacture of fermented foods.

lactic-acid cycle an alternative name for **Cori cycle**.

lactic-acid fermentation a general name for **heterolactic fermentation** and/or **homolactic fermentation**.

lactic acidosis a clinical condition of persistent raised blood lactate concentration, usually above 5 mmol L^{-1} , with a lowered blood pH. It may be caused by severe exercise, cardiovascular insufficiency, hypoxia, shock, drug intoxication, and some inborn errors of metabolism. Compare **hyperlactatemia**.

lacticin any of a family of pore-forming peptidic toxins with about 50 amino acid residues, permitting passage of small solutes, including water. They are produced by *Lactobacillus lactis* and are classified in the TC system under number 1.A.27.

lactide any intermolecular cyclic ester formed by self-esterification from two (or more) molecules of a hydroxy carboxylic acid. Compare **lactone**.

lactifer a special cell, found in the bark of the rubber tree (*Hevea*), in which rubber latex accumulates.

lactim any intramolecular cyclic carboximidic acid produced by the formal removal of a molecule of water between the amino and the carboxyl groups of an amino carboxylic acid other than an α -amino acid. A prefix (as in β -lactim) may be used to designate the position of the amino group in the parent compound. A lactim commonly exists in tautomeric equilibrium with its corresponding **lactam**.

lactitol 4-O- β -D-galactopyranosyl-D-glucitol; a disaccharide used as a sweetener.

lacto+ or (before a vowel) **lact+** *comb. form* indicating milk.

lactobacillic acid (1R-cis)-2-hexylcyclopropanedecanoic acid; 11,12-methyleneoctadecanoic acid; a lipid constituent of various microorganisms, including *Lactobacillus arabinosus*.

Lactobacillus a genus of Gram-positive, anaerobic or facultatively aerobic, straight or curved bacilli or coccobacilli. Their metabolism is fermentative and all species form lactate as the major end product of glucose fermentation. Various species of lactobacilli are important in the preparation of certain fermented foods, e.g. cheese, yogurt, sauerkraut.

Lactobacillus bulgaricus factor an alternative name for **pantetheine**.

Lactobacillus casei factor an alternative name for **folic acid**.

lactobionic acid the **aldonic acid** obtained by the oxidation of lactose.

lactochrome a former name for **riboflavin**.

lactocin any of a family of pore-forming peptidic toxins with about 25 amino acid residues, permitting passage of small solutes, including water. They are produced by *Lactobacillus sake* and are classified in the TC system under number 1.A.23.

lactococcin designation of three different families of peptidic pore-forming toxins, produced by Gram-positive bacteria; they contain 65–75 amino acid residues (lactococcin A family, TC 1.C.22), or 40+35 amino acid residues (lactococcin G family, TC 1.C.25) or 50–100 amino acid residues (lactococcin 972 family, TC 1.C.37).

lactoferrin or **lactotransferrin** a **transferrin** present in milk. Its level in human plasma may be elevated in pancreatitis.

lactoflavin or **lactoflavine** a former name for **riboflavin**.

lactogen 1 any agent that stimulates the secretion of milk. 2 **placental lactogen** an alternative name for **choriomammotropin**. —**lactogenic** *adj.*

lactogenic hormone an alternative name for **prolactin**.

β -lactoglobulin see **beta lactoglobulin**.

lactonase 1 EC 3.1.1.17; *recommended name*: gluconolactonase; *sys-*

tematic name: D-glucono-1,5-lactone lactonohydrolase; *other name:* adonolactonase. An enzyme that catalyses the reaction:

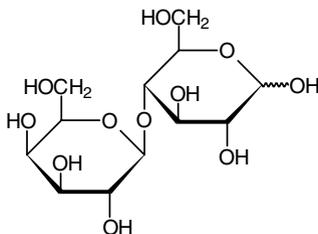

it also acts on a wide range of hexono-1,4-lactones. **2 1,4-lactonase** or **γ -lactonase** EC 3.1.1.25; an enzyme that specifically hydrolyses 1,4-lactones having 4–8 carbon atoms to the corresponding 4-hydroxyacids.

lactone any intramolecular cyclic ester produced by the formal removal of a molecule of water between the hydroxyl and the carboxyl groups of a molecule of a hydroxy carboxylic acid other than an α -hydroxy acid. A prefix (as in β -lactone) may be used to designate the position of the hydroxyl group in the parent compound. *Compare lactide.*

lactoperoxidase a special name for **peroxidase** (def. 2) from milk. It also catalyses the oxidation of iodide to iodine, hence it is useful in radioiodine labelling of proteins and other biological materials under mild conditions.

lactose or (formerly) **milk sugar** the trivial name for the **disaccharide** 4-O- β -D-galactopyranosyl-D-glucose. It constitutes roughly 5% of the milk of almost all mammals (human milk 6.7%; cow's milk 4.5%). It occurs rarely in plants, e.g. in the anthers of *Forsythia* spp. *See also allolactose.*

lactose fermenter *jargon term* for any genus, species, or strain of microorganism that ferments lactose.

lactose intolerance a syndrome occurring in humans with congenital or acquired intestinal **lactase deficiency** in response to the ingestion of lactose (in milk). The failure to hydrolyse lactose leads to its accumulation in the intestine and consequent osmotically induced net fluid secretion into the gut, rapid intestinal transit, and acid stools due to bacterial fermentation of lactose. The condition is particularly prevalent in the Orient.

lactose operon *see lac.*

lactose permease an H⁺-lactose symporter in *Escherichia coli*. It has 12 transmembrane helices but is not very closely related to most other members of the superfamily.

lactose synthase EC 2.4.1.22; *systematic name* UDPgalactose:D-glucose 4- β -D-galactotransferase; *other name:* UDPgalactose-glucose galactosyltransferase. An enzyme that catalyses the reaction:

In mammary gland the protein comprises *N*-acetylglucosamine synthase, the A protein, and α -lactalbumin (*see lactalbumin*), the B protein, both of which are required for lactose synthesis.

lactose-tolerance test a procedure used in the investigation of suspected **lactase deficiency**. Blood-glucose concentrations are estimated before an oral dose of lactose (1 g per kg body mass) and thereafter at 30-min intervals for 2 h. In normal individuals an increase of at least 30 mg per 100 ml (0.167 mM) in the blood-glucose concentration above the fasting value is observed.

lactosuria the presence of lactose in the urine. It is not uncommon during late pregnancy and lactation, or if the flow of milk is prevented.

lactosyl either of the glycosyl groups formed from lactose by detaching the anomeric (α or β) hydroxyl group on C-1.

lactotransferrin an alternative name for **lactoferrin**.

lactotroph any of a class of irregular, granulated, acidophilic cells of the anterior pituitary gland that secrete prolactin. Their number increases greatly during pregnancy.

lactotrophic describing any agent that induces normal growth and development of the mammary gland and sustains it.

lactotropic describing any agent that acts on the mammary gland to induce changes in its metabolism.

lactotropic hormone an alternative name for **prolactin**.

lactotropin an alternative name for **prolactin**.

lactoyl the acyl group, CH₃-CH(OH)-CO-, derived from lactic acid.

lactulose the trivial name for 4-O- β -D-galactopyranosyl-D-fructofuranose; a semisynthetic disaccharide, prepared from lactose, that is sweeter than lactose but less sweet than sucrose. Concentrated solutions of lactulose are useful clinically as an osmotic laxative.

lactyl a former term for **lactoyl**.

lacY a gene in *Escherichia coli* for **lactose permease**.

lacZ a gene in the *lac* operon of *E. coli* encoding β -galactosidase, it is widely used as a reporter gene.

lacZdelta M15 a mutant form of the *E. coli* β -galactosidase gene in which the sequence encoding the N-terminal region corresponding with the α -peptide is deleted. *E. coli* strains carrying this deletion are used to test for α -complementation.

LAD *abbr. for leukocyte adhesion deficiency.*

ladder *informal*, one of many types of DNA molecular size markers, an example is the 1 kb ladder.

L1 adhesion molecule a type I membrane glycoprotein involved in neuron–neuron adhesion, neurite fasciculation, outgrowth of neurites, etc. It is a member of the immunoglobulin superfamily, and has fibronectin domains.

Laetrile *see amygdalin.*

laevo- a variant spelling (*esp. Brit.*) of **levo-**.

laevo+ a variant spelling (*esp. Brit.*) of **levo+**.

laevodopa a variant spelling (*esp. Brit.*) of **levodopa**.

laevorotation a variant spelling (*esp. Brit.*) of **levorotation**.

laevulose a variant spelling (*esp. Brit.*) of **levulose**.

LAF *abbr. for lymphocyte-activating factor* (i.e. **interleukin 1**).

laforin a protein-tyrosine phosphatase present in many tissues. Mutations lead to Lafora disease, a progressive myoclonus epilepsy with intellectual decline, accumulation of glycogen in brain, skin, and liver, and early death.

lagging strand the DNA strand that is synthesized by the joining together of short **Okazaki fragments**, giving the effect of continuous 3' to 5' synthesis in the direction of fork movement during the discontinuous replication of duplex DNA. *Compare leading strand.*

lag phase 1 the initial phase of the growth of a bacterial culture during which the rate of increase of cell numbers remains static, before rising to a value determined by environmental conditions. The extent of the lag phase is determined by the cultural history of the cells of the inoculum and the chemical and physical conditions of the medium into which they are placed. **2** a period of comparatively low activity after the start of an enzymic reaction that involves enzymes that act at a surface, e.g. phospholipases. It is due to the slow formation of the complex between the enzyme and the substrate interface. Once this has been formed the reaction accelerates.

lake to lyse erythrocytes, especially by suspending them in a hypotonic medium.

Laki-Lorand factor *abbr.:* LLF or L-L factor; an alternative name for factor XIII; *see blood coagulation.*

lambda *symbol:* λ (lower case) or Λ (upper case); the eleventh letter of the Greek alphabet. For uses *see Appendix A.*

lambda chain or **λ chain** *symbol:* λ ; one of the two types of **light chain** of human immunoglobulins, the other type being a kappa chain.

lambda DASH a proprietary bacteriophage λ replacement vector used for cloning DNA fragments of up to 20 kb.

lambda FIX a proprietary bacteriophage λ replacement vector used for cloning DNA fragments of up to 20 kb.

lambda gt10 a bacteriophage λ insertion vector used for cloning DNA fragments of up to 8 kb.

lambda gt11 a bacteriophage λ insertion vector used for cloning DNA fragments of up to 8 kb and designed to allow expression of proteins encoded by DNA inserts.

lambda insertion vector one of a number of bacteriophage λ cloning vectors in which the cloned sequence is inserted into a single

restriction endonuclease site. The size constraints on packaging bacteriophage λ recombinant DNA limits the size of insert to <8 kb, consequently making them most suitable for cloning cDNA.

lambda phage or **λ phage** a temperate phage that infects *Escherichia coli* and contains linear duplex DNA, which circularizes during infection; the genome is 48 514 bp. Important gene clusters include those for the head and tail genes, recombination (*att*, *int*, *xis*, α , β , γ), lysis, and regulatory genes. Of the regulatory genes (*cIII*, *N*, *cI*, *cro*, *cII*, *O*, *P*, *Q*), two are immediate-early genes, *cro* and *N*; *cro* prevents synthesis of the repressor (see **prophage**) and turns off expression of immediate-early genes, including itself, after its product, *cro*, binds to *O*. Lambda phage is an example of the antitermination mechanism of phage control (see **antiterminator**); *N* codes for an antitermination factor that allows transcription to proceed through the terminator to the delayed-early genes, *cII* and *cIII*, and *Q* codes for an antitermination factor that allows host RNA polymerase to proceed to the late (lytic) genes. The lytic cycle is repressed by expression of *cI*, the product of which acts at the operator *O* to prevent use of the promoter *P*. Lambda phage has been widely used as a vector in cDNA technology; foreign DNA can be inserted into the chromosome, and some foreign genes can be expressed using the lambda promoters. The linear DNA has cohesive ends that, when the DNA circularizes, associate to form the **cos site** (cohesive end site), which is important in packaging. The *cos* site has been exploited in the formation of **cosmids**.

lambda pipette colloquial term for a pipette used for the transfer of volumes in the microlitre range.

lambda replacement vector one of a number of bacteriophage λ cloning vectors designed for the cloning of DNA inserts of up to 20kb. The size constraints on packaging bacteriophage λ recombinant DNA necessitates the removal of a 'stuffer fragment' located between a pair of identical restriction endonuclease sites before the insertion of the DNA to be cloned. They are used for cloning fragments of genomic DNA.

lambda repressor or **λ repressor** the product of gene *cI*; it is responsible for maintenance of phage λ **prophage**. Its product binds to the operator associated with the RNA polymerase promoter, thus preventing RNA polymerase from initiating transcription. The phage genome then cannot enter the lytic cycle. Mutants in this gene cannot maintain **lysogeny**.

lambda ZAP a proprietary bacteriophage λ insertion vector in which DNA fragments of up to 8 kb are cloned into the multiple cloning site of the pBluescript plasmid incorporated between the left and right arms of the λ vector. The vector permits the excision of the plasmid with its insert in the form of bacteriophage M13 when *E. coli* strains infected with λ ZAP are superinfected with M13 helper phage.

Lambert-Beer law another name for **Beer-Lambert law**.

Lambert's law (of absorption) a physical law in which **Bouguer's law** was re-expressed; put into modern terms, it states that the fraction of monochromatic light (or other electromagnetic radiation) absorbed by a system is independent of the incident **radiant power**, Φ_0 . The law holds only if Φ_0 is small and other factors such as reflection, scattering, and photochemical reactions are negligible. See also **Beer-Lambert law**. [After Johann Heinrich Lambert (1728–77), German mathematician and physicist who stated it in 1760.]

lamella (*pl. lamellae*) any thin layer, membrane, or platelike structure, e.g. one of the series of double membranes that carry the photosynthetic pigments in chloroplasts, one of the thin layers of calcified bone matrix, or one of the spore-bearing gills of the fruiting bodies of mushrooms or related fungi. —**lamellar** or **lamellate** *adj.*

lamellar phase one type of **liquid-crystalline phase**.

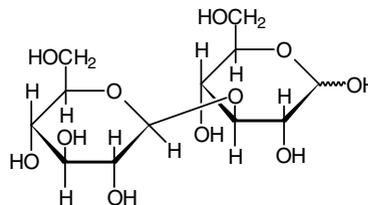

lamin any of a group of intermediate-filament proteins that form the fibrous matrix (**nuclear lamina**) on the inner surface of the nuclear envelope. They are classified as lamins A, B, and C. See also **gliadin**.

lamina (*pl. laminae*) **1** any thin plate or layer, e.g. of bone or mineral. **2** (*in botany*) **a** the blade of a leaf or petal. **b** the flattened part of the thallus of certain algae. See also **basal lamina**, **nuclear lamina**. —**lamellar** *adj.*

laminar flow a form of nonturbulent flow of a fluid in which parallel layers (laminae) of the fluid are moving in the same direction but with different velocities.

laminar-flow cabinet another name for **safety cabinet**.

laminaribiose the disaccharide, 3-O- β -D-glucopyranosyl-D-glucose; a unit of the seaweed polysaccharide **laminarin**.

pyranose form

laminarin a β -1,3-glucan reserve polysaccharide in some brown algae (*Laminaria* spp.). It contains **laminaribiose**.

laminin a glycoprotein that is the major constituent of basement membranes. It consists of three chains, bound to each other by disulfide bonds into a cross-shaped molecule having the appearance of one long and three short arms, with globules at each end (the three chains are wound together in a helical conformation for two thirds of their length, but diverge at the N-terminal end into the three arms that form the apex and side arms of a cross). The molecule interacts with procollagen type IV. Laminin mediates the attachment, migration and organization of cells into tissues during embryonic development by interacting with other extracellular-matrix components. Laminins of varying composition and sequence have been categorized as laminins 1 to 5. Laminin 5 is also known as **kalinin**.

laminin receptor any protein, especially an **integrin** (see also **VLA**), that binds laminin, interacting with it to promote cell adhesion and migration.

Lamm equation a general hydrodynamic equation describing the mass transport of a two-component system during ultracentrifugation. It is:

$$dc_2/dt = (1/x) d\{x[D(dc_2/dx) - c_2s\omega^2x]\}/dx,$$

where c_2 is the concentration of solute molecules at distance x from the axis of rotation, D is the translational diffusion constant, ω is the angular velocity, and s is the sedimentation coefficient.

LAMP *abbr. for* **1** lysosomal-associated membrane protein. One of three membrane glycoproteins that shuttle between lysosomes, endosomes and the plasma membrane. They are heavily glycosylated and are thought to protect lysosomal membranes from attack by lysosomal enzymes. LAMP-1 deficient mice have a mild phenotype but LAMP-2 deficient mice have severe symptoms arising from the accumulation of autophagic vesicles in numerous tissues. LAMP-2 deficiency is the primary defect in Danon disease, a lysosomal glycogen storage disease with normal acid maltase activity. LAMP-3 is CD63 a member of the **tetraspanin** superfamily. **2** Linux Apache MySQL PHP; a popular software raft for a WWW server, relational database, and interrogatory software.

lampbrush chromosome any of the large diplotene chromosomes found in the oocytes of many animals. They are up to 1mm long and are covered with loops projecting in pairs from most chromosomes; each loop has a core of DNA and is the site of active gene expression.

lamprin a self-aggregating extracellular cartilage protein of lampreys, aggregates of which form fibres rich in beta structure. It is a major structural protein isolated from the annular cartilage of the lamprey, similar in amino-acid composition to **elastin**, but it does not contain desmosine or isodesmosine.

Lan symbol for lanthionine.

lan+ *comb. form* indicating wool. [From Latin *lana*, wool.]

Landsteiner-Weiner antigen *abbr.:* LW antigen; see **Rhesus factor**.

lane any of a set of parallel tracks resulting from the simultaneous separation of similar samples by one-dimensional zone electrophoresis or chromatography in thin-layer media.

Langendorff perfused heart a nonworking rodent heart preparation maintained *in vitro* by perfusion into the aorta with an oxygenated fluid so that the fluid circulates primarily into the coronary arteries. It is useful for studying the metabolism of heart muscle. A number of improvements of the original preparation have been made since its introduction. [After O. Langendorff (1853–1909), German physiologist.]

Lang-Levy pipette a type of constriction micropipette (5–500 μL) that is self-adjusting and very reproducible.

Langmuir adsorption isotherm an equation describing the fraction of the surface of an adsorbent covered with a monomolecular layer of an adsorbed gas, arrived at from a consideration of the number of gas molecules striking and leaving the surface in a given time. It is:

$$V/V_m = k_1 p / (1 + k_2 p),$$

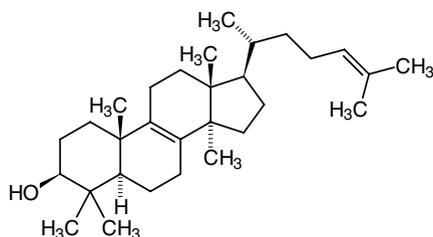

where V is the volume of gas adsorbed, V_m is the volume of gas required to cover the whole surface, p is the gas pressure, and k_1 and k_2 are constants for the system. *Compare Hill-Langmuir equation.* [After Irving Langmuir (1881–1957), US physical chemist and inventor.]

Langmuir-Blodgett multilayer a thin film of oriented amphiphilic molecules, consisting of superposed monolayers built up by successive dipping and withdrawing of a solid substrate, e.g. a glass slide, through an insoluble monolayer of an appropriate amphiphilic substance (or mixture of such substances) spread on the surface of an aqueous solution and kept at constant pressure. [After Irving Langmuir and Katharine B. Blodgett (1898–1979).]

Langmuir trough an apparatus for measuring the dependence of the surface force exerted by a film of a substance (of low vapour pressure), floating on a liquid with which it is immiscible, on the area of the film. The apparatus consists of a rectangular tank containing the subnatant liquid, e.g. water, on which a known amount of the immiscible substance, e.g. an oil or a higher fatty acid, is spread between two parallel barriers to form a film. One of the barriers is fixed and the other may be moved so as to compress the film to a predetermined area. The force exerted on the film to achieve any given area is measured by a system of levers and either a torsion wire or balancing masses.

lanolin or **wool fat** the fatlike secretion of the sebaceous glands of sheep that is deposited onto the wool fibres. It is a wax consisting of esters and polyesters of over 30 aliphatic, steroid, and triterpenoid alcohols and a similar number of fatty acids. Lanolin normally contains 25–30% water and is widely used as an ointment base. *See also lan+*.

lanosterol kryptosterol; lanosta-8,24-dien-3 β -ol; a steroid alcohol (triterpene) originally obtained from **lanolin**. It occurs in the biosynthetic pathway from squalene 2,3-epoxide to cholesterol in animals and fungi, but not in photosynthetic tissues, where it is replaced by **cycloartenol**. *See also lanosterol synthase.*

lanosterol synthase EC 5.4.99.7; *other names:* 2,3-epoxysqualene-lanosterol cyclase; oxidosqualene-lanosterol cyclase (*abbr.:* OSC); an enzyme of the pathway for the synthesis of sterols. It catalyses the cyclization of (S)-2,3-epoxysqualene to lanosterol.

lantern *see* firefly lantern.

lanthanoid or **lanthanide** or (*formerly*) **lanthanon** any member of the series of 15 metallic elements with atomic numbers 57 (lanthanum) to 71 (lutetium) inclusive that occur together in group 3 and period 6 of the IUPAC **periodic table**; sometimes the term is restricted to the

14 elements following lanthanum. Lanthanoid is now the preferred name. Together with the elements scandium and yttrium, the lanthanoids are known also as **rare-earth elements** or (*more loosely*) **rare earths** (the latter term referring strictly to their oxides). They mostly occur widely in nature, albeit in small amounts. Apart from the element of atomic number 61 (promethium), all lanthanoids have at least one stable nuclide and occur naturally, the principal source being the mixed phosphate ore monazite. All nuclides of promethium, however, are radioactive, and (except for traces possibly occurring as a fission product of natural uranium) all are artificial. The lanthanoids are strongly electropositive, and their chemical properties are similar, due usually to the filling of an inner electron subshell (4f) progressively across the series. Like the **actinoids**, they thus represent a series of inner transition elements within the series of **transition elements** embraced by groups 3 to 11 inclusive. Some paramagnetic lanthanoid ions induce strong shifts in the positions of many NMR spectral peaks and have been used as relaxation and shift probes in structural studies employing NMR spectroscopy.

lanthionine (2S,6R)-lanthionine, *meso*-lanthionine, S-(alanin-3-yl)-L-cysteine, 2,2'-diamino-3,3'-thiobis(propionic acid); *symbol* (recommended):

or Lan; a di(α -amino acid) found in **lantibiotic** polypeptides. It is formed as a post-translational modification, the first step involving dehydration of a Ser to the α,β -unsaturated amino-acid residue, 2,3-didehydroalanine. A bond is then formed between the =CH₂ group thus formed and the sulfur atom of a cysteine, inversion of configuration of the α carbon of the Ser-derived moiety occurring in the process. Chick embryo protein contains the (2R,6R) diastereoisomer. Lanthionine is also formed artefactually by the mild alkaline treatment of wool, hence its name (*see lan+*).

lantibiotic any of a number of polypeptides, of 1.89–4.63 kDa, that contain **lanthionine** or methylanthionine (*threo*- β -methylanthionine, (2S,3S,6R)-3-methylanthionine), and have antibiotic action. They are produced by, and primarily act on, Gram-positive bacteria. In addition to lanthionines, they contain the amino acids 2,3-didehydroalanine (*abbr.:* Dha) and 2,3-didehydrobutyryne (2-aminocrotonic acid, (Z)-2-aminobut-2-enoic acid, *abbr.:* Dhb), resulting from dehydration of serine and threonine residues respectively. These amino acids are formed post-translationally from normally-coded amino acids. Lantibiotics are broadly divided into type A, elongated amphiphilic peptides, and type B, compact globular peptides. Type-A peptides kill bacterial cells by forming pores in the cytoplasmic membrane, type-B peptides possibly acting by enzyme inhibition.

LAP *abbr. for* 1 lamin-associated protein; any of the integral proteins of the inner nuclear membrane that bind to **lamins**. LAPs include several isoforms of LAP1 and LAP2, lamin B receptor, and emerin. **2** (*in clinical chemistry*) leucine aminopeptidase (LAS preferred).

LA-PF4 *abbr. for* low-affinity platelet factor 4; *other name:* connective-tissue activating peptide III (*abbr.:* CTAP-III). A protein (83 amino acids) derived from **platelet basic protein precursor** (94 amino acids). It stimulates DNA synthesis, mitosis, glycolysis, intracellular cyclic AMP accumulation, prostaglandin E₂ secretion, and synthesis of hyaluronic acid and sulfated glycosaminoglycan.

Laplace transform method a method that enables solutions of linear differential equations with constant coefficients to be found by reference to tables of Laplace transform pairs, with a minimum of mathematical work. The Laplace transform of a function $y = F(t)$ is defined by:

$$F(s) = \int_0^{\infty} e^{-st} F(t) dt$$

in which s is usually a complex quantity and must have a positive real term, so that e^{-st} will be zero when $t = \infty$. [After Pierre Simon, Marquis de Laplace (1749–1827), French astronomer and mathematician.]

Largactil *see* chlorpromazine.

large calorie *an alternative name for kilocalorie or (in nutrition) Calorie.*

large-patch repair (of DNA) *a name sometimes given to the process of excision repair of duplex DNA in some mutant organisms, e.g. polA⁻ Escherichia coli, in which the newly synthesized polynucleotide 'patch' is considerably larger than in the wild type.*

large T-antigen *see* T antigen (def. 1).

lariat a lasso-shaped structure formed from the fragment of RNA to be excised during the process of splicing out the introns in the primary transcript of eukaryotic genes.

lariat debranching enzyme an enzyme that cleaves the 2',5'-phosphodiester bond formed during pre-mRNA splicing between the 5'-terminal guanylyl residue of the intron and an adenylyl residue near the 3' splice site, at the branch point of excised intron lariats. It is involved in the turnover of excised introns.

Larmor frequency the angular frequency of Larmor precession of an atomic electron.

Larmor precession the precession of a charged particle moving under the influence of a central force, e.g. of an orbiting electron in an atom, when acted on by an external magnetic field. [After Joseph Larmor (1847–1942), Irish-born physicist.]

LAS (*in clinical chemistry*) *abbr. for* leucine aminopeptidase (preferred alternative to LAP).

lasalocid *or* X-537A any of five closely related lipophilic antibiotics, lasalocids A–E, isolated from cultures of *Streptomyces lasaliensis*. Lasalocid A ($M_r = 591$) is a carboxylic ionophore for virtually every known cation, but transports monovalent cations about ten times more effectively than divalent cations.

lased light *an imprecise term for* laser light; *see* laser (def. 2).

laser 1 any device for producing an intense, coherent, monochromatic, parallel beam of light (or other electromagnetic radiation) by stimulated emission. A laser consists of an optically transparent cylinder containing an active medium bounded by a full mirror at one end and by a partial mirror at the other end. Some chemical species of the medium are excited above their ground state by application of electromagnetic radiation from an external source; the excited species revert to their ground state with the emission of a photon, which in turn can collide with other excited species to produce stimulated emission of other photons. **2** having the characteristic quality of, being, or using, light emitted by a laser (def. 1), as in laser densitometry, laser ionization (micro) mass spectrometry, laser light, laser microprobe mass analysis, laser nephelometry, laser photolysis, laser (light) scattering, laser spectrophotometry, and laser velocimetry. [Acronym from light amplification by stimulated emission of radiation.]

Latapie mincer a device for mincing tissues for metabolic studies in which both the rate of rotation of the cutting disks and the rate at which the tissue is forced against these disks may be controlled by varying the rates at which two cranks are turned, thus enabling minces of different degrees of fineness to be obtained. Sterile conditions may be maintained during the mincing if desired.

late enzyme *see* late gene.

late gene any gene of a bacteriophage or other viral genome that is expressed significantly, as a late enzyme or other late protein, only after replication of the genome has started. *Compare* early gene.

latency 1 *or* crypticity the state or quality of being latent. **2** *an alternative term for* latent period.

latent 1 existing in a potential, dormant, or suppressed form but usually capable of being expressed or evoked. **2** (*in pathology*) (of an infection or disease) not yet manifest or apparent.

latent enzyme any enzyme whose activity only becomes manifest when the conditions are changed. The term is used especially of a particulate enzyme that becomes active when the particles are disrupted.

latent heat *symbol:* L ; the change in the heat content of a (given amount of) substance when it changes phase without change in its temperature.

latent image (*in photography*) the invisible image produced by the action of light, etc. on the photosensitive emulsion that is made visible by development.

latent period *or* latency **1** the time between the arrival of a stimulus at an irritable tissue and the beginning of the appropriate response.

2 the time between the adsorption of virulent bacteriophage onto a bacterium and lysis with liberation of newly formed virions.

late protein *see* late gene.

lateral gene transfer *or* horizontal gene transfer the transfer of genes between species, e.g. for antibiotic resistance in bacteria.

lateral phase separation the phenomenon of coexistence of solid and liquid regions in a lipid bilayer at temperatures between the pre-transition temperature and the transition temperature.

lathyrism any abnormal state that results from ingesting any of several toxins found in plants of the genus *Lathyrus*. In humans one kind is characterized by a spastic paraplegia of the lower extremities associated with degenerative changes in the lateral pyramidal tracts of the spinal cord. It is caused by ingestion of neurotoxins, e.g. β -cyano-L-alanine and L- α , γ -diaminobutyric acid. These are also present in the common vetch (*Vicia sativa*). In experimental animals a defect of cross-linking of collagen is caused by feeding sweet pea (*Lathyrus odoratus*) seeds; the toxic substance was identified as β -(γ -L-glutamyl)aminopropionitrile but β -aminopropionitrile alone is fully active. Turkeys fed *L. odoratus* died of hemorrhage from rupture of the aorta.

lathyrigen any substance that on ingestion induces the disease lathyrism.

Latin square (*in statistics*) a square array of n columns and n rows containing n different elements and in which no element occurs more than once in any row or column. It is used as a basis of experimental procedures when it is desired to allow for two sources of variability while investigating a third.

LATS *abbr. for* long-acting thyroid stimulator.

lattice 1 any regular array of objects or points in two or three dimensions. **2** (*in crystallography*) any regular, three-dimensional array of fixed points about which atoms, ions, or molecules vibrate in a crystal. **3** (*in immunology*) the three-dimensional aggregate suggested to be built up in an antigen–antibody reaction (*see* lattice hypothesis).

lattice energy (of a crystal) the energy that would be required to separate the ions of a crystal to an infinite distance from each other.

lattice hypothesis a hypothesis describing antigen–antibody reactions in terms of the building up of large antigen–antibody aggregates or three-dimensional lattices. The hypothesis requires both antigen and antibody to have valencies greater than one.

Lau *symbol for* the dodecanoyl (i.e. lauroyl) group.

Laue equation any of a set of three equations describing the occurrence, positions, and intensities of X-ray beams after diffraction by a crystal. For three crystal axes, x , y , and z , with separations of chemical entities along them of a , b , and c , respectively, the equations are:

$$a(\cos\alpha - \cos\alpha_0) = h\lambda,$$

$$b(\cos\beta - \cos\beta_0) = k\lambda,$$

and

$$c(\cos\gamma - \cos\gamma_0) = l\lambda,$$

where α_0 , β_0 , and γ_0 are the angles that the incident beam makes with the x , y , and z , axes, respectively, and α , β , and γ are the corresponding angles for the diffracted beam; λ is the wavelength of the radiation and h , k , and l are integers corresponding to the Miller indices of the planes considered to be diffracting the radiation. *See also* Bragg's law. [After Max Theodor Felix von Laue (1879–1960), German physicist.]

Laue photograph *or* Laue pattern the spot diagram produced when a heterogeneous beam of X-rays is diffracted by passage through a crystal.

laurate 1 *the trivial name for* dodecanoate, $\text{CH}_3\text{-(CH}_2\text{)}_{10}\text{-COO}^-$, the anion derived from lauric acid (i.e. dodecanoic acid), a saturated straight-chain higher fatty acid. **2** any mixture of free lauric acid and its anion. **3** any salt or ester of lauric acid. Dodecyl laurate is one of the main components of laurel oil, the oil obtained from

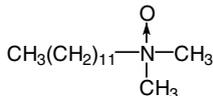

berries of the laurel plant, *Laurus nobilis*. Laurate is present in appreciable amounts in hydrolysates of phosphoglycerides of plants and animals.

Laurell technique an alternative name for **rocket immunoelectrophoresis**. [After C.-B. Laurell, Swedish biochemist.]

lauroyl or (formerly) **lauryl** symbol: Lau; the trivial name for dodecanoyl, $\text{CH}_3\text{-(CH}_2\text{)}_{10}\text{-CO-}$, the acyl group derived from lauric acid (i.e. dodecanoic acid). It occurs in natural lipids, mainly as acylglycerols.

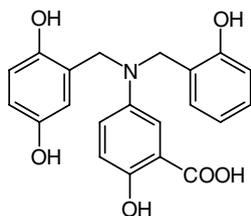

lauyl 1 symbol: Dod; a common name for dodecyl, $\text{CH}_3\text{-(CH}_2\text{)}_{10}\text{-CH}_2\text{-}$, the alkyl group derived from dodecane; use deprecated. **2** a former trivial name for dodecanoyl (lauroyl now used).

lauryldimethylamine oxide abbr.: LDAO; *N,N*-dimethyl-*N*-dodecylamine oxide; a water-soluble, zwitterionic (at pH 7 or above) detergent, aggregation number 76, CMC 1–2 mM.

lauryl sulfate, sodium salt an alternative name for **sodium dodecyl sulfate**.

lavendustin any substituted amino salicylic acid that is used as a protein tyrosine kinase inhibitor. Lavendustin A is 5-amino-[(*N*-2,5-dihydroxybenzyl)-*N'*-2-hydroxybenzyl]aminosalicylic acid and lavendustin C is 5-(*N*-2,5-dihydroxybenzyl)aminosalicylic acid. Lavendustin A inhibits protein-tyrosine kinase activity with little effect on cyclic AMP-dependent kinase or protein kinase C. Lavendustin C is similar but also inhibits Ca^{2+} /calmodulin kinase II.

lavendustin A

lawn a layer of microorganisms uniformly distributed in or over the surface of a solid culture medium.

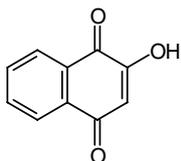

law of conservation of energy see **thermodynamics, laws of**.

law of independent assortment see **Mendel's laws of heredity**.

law of mass action see **mass action**.

laws of thermodynamics see **thermodynamics**.

lawsone 2-hydroxy-1,4-naphthoquinone; the active dyeing compound of **henna**.

layer line one of the parallel lines of spots obtained on the photographic plate in the rotating crystal method of X-ray diffraction analysis.

lb symbol for pound.

LB abbr. for Luria-Bertani medium a synthetic culture medium commonly used for the growth of bacteria.

LBF abbr. for *Lactobacillus bulgaricus* factor (see **pantetheine**).

L-bifunctional enzyme see **peroxisomal bifunctional enzyme**.

LC abbr. for liquid chromatography.

LCAD abbr. for long-chain acyl-CoA dehydrogenase; see **beta-oxidation system**.

LCAT abbr. for lecithin-cholesterol acyl transferase.

LCD abbr. for liquid-crystal display.

L cell an alternative name for **EG cell**.

L chain see **light chain** (def. 1).

LCK a gene family encoding nonreceptor tyrosine kinases (e.g. p56^{Lck} or lymphocyte-specific protein-tyrosine kinase) of the Src family (see **src**), first detected in the LSTRA murine lymphoma cell line.

The product is lymphocyte-specific and is activated by binding to the intracellular domains of CD3 and CD4 in T lymphocytes. The mitogen-activated protein (MAP) kinase is a substrate for p56^{Lck} , which is a myristoylated protein with SH2 and SH3 domains. A rare mutation in the gene at 1p35-p34.3 leads to Lck deficiency and a form of severe combined immunodeficiency.

LCR abbr. for **1** locus control region. **2** ligase chain reaction.

LD abbr. for **1** lethal dose. **2** (in *clinical chemistry*) L-lactate dehydrogenase (alternative to LDH); see also **HBD**. **3** low density.

LD₅₀ abbr. for median lethal dose.

LDH abbr. for L-lactate dehydrogenase (alternative to LD).

LDL abbr. for low-density lipoprotein.

LDL receptor a cell-surface receptor that binds apolipoprotein B and so internalizes **low-density lipoprotein** (LDL) from the plasma, leading to processing that regulates cholesterol and LDL synthesis, and hence plasma cholesterol concentration. It is a type I membrane protein. The number of LDL receptors on liver cells is regulated by cholesterol synthesis: when cholesterol levels rise, the number of receptors falls. Defects in this receptor are associated with certain forms of type II **hyperlipidemia**. The amino end of the extracellular domain contains seven or eight 40-residue repeats; each repeat has about six Cys residues, all of which are involved in disulfide bonds; following these repeats is a region of about 350 residues that is homologous with part of the epidermal growth factor precursor.

LDL receptor-related protein see **LRP**.

Le abbr. for Lewis antigen.

LE392 a strain of *E. coli* favoured for the propagation of bacteriophage lambda.

leaching (microbial) a process for the solubilization of metals, mostly from poor ores, by lithotrophic bacteria. See also **lithotroph**.

lead symbol: Pb; a very soft, bluish-white metallic element of group 14 of the IUPAC **periodic table**. It has a low melting point and high relative density; proton number 82; relative atomic mass 207.2. It is commonly used for shielding from ionizing radiation.

lead compound 1 (in *pharmacology*) a molecule that serves as the starting point for development of a drug, typically by variations in structure for optimal efficacy. **2** (in *chemistry*) a compound of lead (Pb).

leader peptidase EC 3.4.99.36; *other name*: signal peptidase I, phage-procoat-leader peptidase; an enzyme that catalyses the cleavage of N-terminal leader sequences from secreted proteins.

leader peptide an alternative name for **signal peptide**.

leader sequence or **lead sequence** an alternative name for **signal sequence** (see **signal peptide**).

leading strand the DNA strand that is synthesized continuously, in the 5' to 3' direction, towards the replication fork during the discontinuous replication of duplex DNA. Compare **lagging strand**.

lead screw a threaded rod the rotation of which is used to drive the tool carriage of a lathe, the plunger of a syringe, etc.

leaf (pl. leaves) 1 the principal organ of photosynthesis and transpiration in higher plants. It typically consists of a flattened blade-like lamina, often relatively broad, attached to the plant stem directly or by a stalk. **2** any thin, flattened object that resembles a leaf. **3** or **terminal tip** (in *phylogeny*) the end of a terminal branch of a phylogenetic tree. Collectively the leaves represent the contemporary taxa in a data set. See also **leaflet**.

leaflet 1 a any small or young leaf (def. 1). **b** an individual segment of a compound leaf. **2** any small, thin, flattened object or structure that resembles the leaf of a plant, especially a lipid bilayer or a portion of a biological membrane.

leak a cellular process whereby ions or other compounds escape through a membrane, dissipating a chemical potential.

leakage *see* leak.

leaky (*in genetics*) describing any mutation that fails to shut off completely the activity of a gene so that some residual expression of the gene remains.

Le antigen *symbol for* Lewis antigen.

LEA protein *abbr. for* late embryogenesis abundant protein; any of the proteins expressed in seeds during maturation and desiccation. Five families have been described. These proteins are hydrophilic, cytoplasmic, and rich in glycine and alanine but lacking in cysteine and tryptophan. Their concentration increases in vegetative parts of plants exposed to water deficit. In rice, overexpression increases resistance to such stress.

least squares a statistical method for determining the 'best' value of an unknown quantity relating one or more sets of measurements or observations. It is based on minimizing the sum of the squares of the deviations of the experimentally determined values from the calculated values, and is used especially to find a curve that best fits a given set of data.

leaving group any atom or group, charged or uncharged, that departs during a substitution or displacement reaction from what is regarded as the residual or main part of the substrate of the reaction.

Lebedev-Saft or **Lebedev juice** an aqueous extract of air-dried yeast. It will ferment glycerone (dihydroxyacetone) and, in the presence of phosphate, produces a hexose phosphate. [After Alexander Nikolaevich Lebedev (1881–1938), Russian botanist who described the preparation in 1911.]

Leber's hereditary optic neuropathy *abbr.:* LHON; a mitochondrial disease of humans manifested as painless, subacute, bilateral visual loss with abnormal colour vision. It is associated with at least eight genes in mitochondrial DNA for components of certain complexes of the electron transport chain. [After Theodor Leber (1840–1917), German ophthalmologist.]

Le Chatelier principle or **Le Chatelier–Braun principle** a principle stating that when a system in equilibrium is subject to stress, i.e. to a change in its conditions, the system will adjust itself to annul, as far as possible, the effect of the stress. [First formulated (in 1885) by Henry (Louis) Le Chatelier (1850–1936), French chemist, and independently in 1886 by Karl Ferdinand Braun (1850–1918), German physicist.]

lecithin *an old trivial name, still in frequent use, for* any 3-*sn*-phosphatidylcholine.

lecithinase any of a number of distinct enzymes acting on lecithins that are now usually considered among the **phospholipases**.

lecithin-cholesterol acyl transferase *abbr.:* LCAT; EC 2.3.1.43; *recommended name:* phosphatidylcholine-sterol *O*-acyltransferase; *other name:* phospholipid-cholesterol acyltransferase. An enzyme glycoprotein, secreted into plasma by the liver, that catalyses a reaction between phosphatidylcholine and cholesterol to form a cholesteryl ester and 1-acylglycerophosphocholine. This enzyme is central to the extracellular metabolism of plasma lipoproteins; it acts on free cholesterol in the high-density lipoprotein (HDL) precursor, transferring a fatty acyl group to cholesterol, thus contributing to the altered class composition of the mature HDL; some of the resulting cholesterol esters are partly taken up by low-density lipoprotein. It is activated by apolipoprotein A1, and is deficient in Norum and fish-eye diseases.

lectin any of a group of specific agglutinins and other antibody-like (glyco)proteins of non-immune origin, defined (by IUBMB) as 'sugar-binding protein or glycoprotein of non-immune origin that agglutinates cells and/or precipitates glycoconjugates'. Lectins are widely distributed in nature, being found mainly in seeds, but also in other parts of certain plants, and in many other organisms, from bacteria to mammals. Lectins bear at least two sugar-binding sites; they bind specific sugars, and thereby precipitate certain polysaccharides, glycoproteins, and glycolipids, and/or agglutinate animal and plant cells. Some can distinguish between normal and malignant cells, and many, e.g. phytohemagglutinin, are mitogenic. They are widely used experimentally, especially **concanavalin A**, as tools in carbohydrate biochemistry, for studying cell surfaces and for inducing **transformation** (def. 3) of lymphocytes. Plant lectins are also known as **phytoagglutinins**.

LED *abbr. for* light-emitting diode.

leeching a form of blood letting in which blood is removed by leeches. *Compare* leaching.

leghemoglobin or (*esp. Brit.*) **leghaemoglobin** a hemoglobin-like red pigment found in the root nodules of leguminous plants. An autoxidizable hemoprotein, it sequesters dioxygen to prevent inhibition of **nitrogenase** in the bacteroids. It is thus essential for symbiotic nitrogen fixation.

legumain EC 3.4.22.34; *other names:* bean endopeptidase; vicilin peptidohydrolase; phaseolin; an endopeptidase from legumes that hydrolyses Asn–Xaa bonds in small molecule substrates such as Boc-Asn–[O]PhNO₂.

legumin a major storage protein of the seeds of both leguminous and non-leguminous plants. It consists of two chains, derived from a common precursor: an acidic α chain and a basic β chain – these are linked by a single disulfide bond.

Leigh syndrome or **necrotizing encephalopathy** a devastating heterogeneous neurodegenerative disease with severe lactic acidosis. It is commonly associated with nuclear mutations in protein components of **complex I, II, III, IV**, and with a mitochondrial mutation in subunit 6 of the F₀F₁ complex of the inner mitochondrial membrane (*see* **H⁺-transporting ATP synthase**). Mutations in other proteins of the mitochondrion (e.g. pyruvate dehydrogenase complex, pyruvate carboxylase) produce a very similar clinical state. [After Denis Leigh (1915–), British psychiatrist.]

LEM *abbr. for* light-effect mediator.

length *symbol:* *l* or *L*; a scalar physical quantity indicating linear extent; one of the seven SI base physical quantities. The SI base unit of length is the **metre**.

lens 1 a piece of glass or other transparent and refracting material, or two or more such pieces joined together, for converging or diverging a beam of light in order to form optical images. **2** any electrostatic or electromagnetic device for focusing or otherwise altering the direction of movement of a beam of electrons or other elementary charged particles; any similar device acting on sound waves. **3** (*in zoology*) any of various transparent structures responsible for focusing light onto photoreceptors. The **crystalline lens** of vertebrates is a near-spherical structure in the eye, lying in the aqueous humour behind the pupil. It focuses or assists in focusing light rays onto the retina. Enclosed within a collagenous capsule, it consists largely of cells containing proteins called **crystallins**.

lenticular 1 having the shape of a biconvex **lens** (def. 1). **2** of or pertaining to a **lens**.

lentinan a polysaccharide isolated from the edible mushroom *Lentinus edodes*. It is a β -1,3-glucan, having for every five β -1,3 linear linkages, two glucopyranoside units in β -1,6 linkage.

lentinarin *see* callose.

lentropin a protein, present in the vitreous humour of the eye, that stimulates lens-fibre differentiation. It is related to **insulin-like growth factors**.

Lepidoptera a large order of insects that includes butterflies, skippers, and moths. The adults are characterized by a prominent coiled proboscis and two pairs of large, scaly, membranous wings. The larvae are caterpillars. —**lepidopteran** *adj.*

leporine of, pertaining to, or resembling a rabbit or hare.

leprachaunism an autosomal recessive inherited disease characterized by small stature and elfin-like appearance, with motor and mental retardation and severe failure to thrive. Most patients die in early childhood, though a few, who are compound heterozygotes for two different alleles, survive childhood. The condition can be caused by any of a number of mutations in the gene encoding the insulin receptor.

leptin a protein encoded by a gene, *ob*, first identified as the *obese* mutation (*see* **ob/ob**) in mice. Leptin may act as a signal in the regulation of adipose mass, possibly by regulating appetite and energy expenditure. It appears to be expressed exclusively in white adipose tissue. The sequence is largely hydrophilic, and has structural features indicative of a secreted protein. *See also* **leptin receptor**.

leptin receptor any member of a widely expressed single-pass transmembrane receptor family that binds **leptin** and exert its effects through the JAK/STAT signalling pathway. It is expressed at high levels in the hypothalamus relative to other tissues. Mutations in

the receptor are responsible for *db* mice, corpulent mice, and Zucker rats, all of which are grossly obese. See also **diabetes mutation**, **ob/ob**.

leptocene the first phase of prophase I in meiosis.

leptotene see meiosis.

Lesch-Nyhan syndrome an X-chromosome-linked, inherited disorder of male humans in which there is an almost complete deficiency of **hypoxanthine phosphoribosyltransferase** (EC 2.4.2.8), a key enzyme of the **salvage pathway** of purine metabolism. The condition is characterized by hyperuricemia, excessive uric-acid biosynthesis, and certain neurological features including self-mutilation, spasticity, and mental retardation. Over 200 mutations in the gene for **HGPRT** cause the syndrome. Death usually occurs in the second or third decade of life. [After M. Lesch (1939–), US paediatrician, and William Leo Nyhan (1926–), US physician and biochemist.]

lesion 1 (*in pathology*) a zone of tissue with impaired function resulting from damage by disease or wounding. **2** (*in biochemistry*) any deleterious disturbance of a metabolic pathway resulting from chemical interference or genetic abnormality.

+less suffix forming adjectives and adverbs without, lacking; unable to do or to be done. In biochemistry it is used especially of auxotrophic mutants to indicate the substance they cannot synthesize, e.g. thymineless mutant.

let23 a gene in *Caenorhabditis elegans* for a receptor **tyrosine kinase** of the epidermal growth factor family. It is probably activated by the **lin3** product. The product of *let23* is a type I membrane glycoprotein.

lethal dose *abbr.*: LD; the amount of a drug or other agent that when administered to an organism causes the organism's death. See also **median lethal dose**.

lethal factor any **lethal mutation**.

lethal gene any gene carrying a **lethal mutation**. Such mutations may only be fatal in the homozygous state.

lethal mutant any organism carrying a **lethal mutation**.

lethal mutation any **mutation** that may bring about the death of the organism before its maturity. The consequences of such a mutation may depend on whether the organism is homozygous or heterozygous for the gene in question, and possibly also on the conditions (see **conditional lethal mutation**).

lethal synthesis any process by which a highly toxic compound is synthesized in an organism from a nontoxic precursor. The classic example is the formation of **fluorocitrate** when e.g. kidney homogenates are incubated with **fluoroacetate**. The fluorocitrate thus formed inhibits **aconitase**.

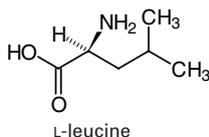

LETS protein *abbr.* for large external transformation sensitive (glyco)protein (i.e. cellular **fibronectin**).

Leu *symbol* for a residue of the α -amino acid L-leucine (alternative to L).

leuc+ a variant spelling of **leuk+**. See **leuko+**.

leucinate 1 leucine anion; the anion, $(\text{CH}_3)_2\text{CH}-\text{CH}_2-\text{CH}(\text{NH}_2)-\text{COO}^-$, derived from **leucine**. **2** any salt containing leucine anion. **3** any ester of leucine.

leucine the *trivial name* for α -aminoisocaproic acid; α -amino- γ -methylvaleric acid; 2-amino-4-methylpentanoic acid; $(\text{CH}_3)_2\text{CH}-\text{CH}_2-\text{CH}(\text{NH}_2)-\text{COOH}$; a chiral α -amino acid. L-leucine (*symbol*: L or Leu), (S)-2-amino-4-methylpentanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: CUA, CUC, CUG, or CUU; UUA or UUG. In mammals, it is an essential amino acid, and is ketogenic. Residues of D-leucine (*symbol*: D-Leu or DLeu), (R)-2-amino-4-methylpentanoic acid, occur in a number of peptide antibiotics, e.g. gramicidins A, B, C, and D, and polymixins D₁, D₂, E₁, and E₂.

leucine aminopeptidase *abbr.* (*in clinical chemistry*): LAP (preferred) or LAS. See **leucine aminopeptidase**.

leucine and valine biosynthesis the biosynthesis of leucine and

valine initially follows a common pathway that commences with the formation of acetolactate from two molecules of pyruvate, a reaction catalysed by acetolactate synthase. Acetolactate is converted via α,β -dihydroxyisovalerate (2,3-dihydroxy-3-methylbutanoate) to α -ketoisovalerate (2-oxo-3-methylbutanoate). At this point the pathway branches. α -Ketoisovalerate can be converted by transamination with glutamate to valine. Alternatively, it can be converted successively to α -isopropylmalate (2-isopropylmalate), β -isopropylmalate (3-isopropylmalate), and α -ketoisocaproate (4-methyl-2-oxopentanoate), and thence by transamination with glutamate to leucine. See also **3-isopropylmalate dehydratase**, **3-isopropylmalate dehydrogenase**.

[5-leucine]enkephalin *abbr.*: [Leu⁵]enkephalin or [Leu]enkephalin; the recommended *trivial name* for the pentapeptide Tyr-Gly-Gly-Phe-Leu. See **enkephalin**.

leucine-rich repeat *abbr.*: LRR; short sequence motif in proteins, of average length 24 residues, containing a high proportion of leucines, typically five to seven at positions 2, 5, 7, 12, 16, 21, and 24 within the repeat. Such arrays form an amphipathic sequence, with leucine as the predominant hydrophobic residue. They are believed to participate in protein-protein or protein-lipid interactions. LRRs form elongated non-globular structures, often flanked by cysteine-rich domains. They were first described in α_2 -glycoprotein, but they have since been found in other proteins. The number of repeats can vary from one, in platelet glycoprotein Ib β , to 30, in, e.g., **chaptin**. The 3-D structure of ribonuclease inhibitor has been shown to contain 15 repeats, and has revealed LRRs to represent a new class of alpha/beta fold.

leucine zipper a domain in a protein structure in which two alpha helices containing leucines (normally four or five) repeating every seventh amino-acid residue, interdigitate in zipper fashion to stabilize the structure. Such an arrangement was originally found in DNA-binding proteins, but it is now known to occur also in other proteins, especially adjacent to proposed transmembrane regions, mediating dimerization. The abbreviation ZIP is used, e.g., in designating the **bZIP** family of proteins. See also **potassium channels**.

leucinium leucine cation; the cation, $(\text{CH}_3)_2\text{CH}-\text{CH}_2-\text{CH}(\text{NH}_3^+)-\text{COOH}$, derived from **leucine**.

leucino the alkylamino group, $(\text{CH}_3)_2\text{CH}-\text{CH}_2-\text{CH}(\text{COOH})-\text{NH}-$, derived from **leucine**.

leuco+ a variant spelling of **leuko+**.

leucocyte a variant spelling of **leukocyte**.

leucyl the acyl group, $(\text{CH}_3)_2\text{CH}-\text{CH}_2-\text{CH}(\text{NH}_2)-\text{CO}-$, derived from **leucine**.

leucyl aminopeptidase EC 3.4.11.1; *other names*: leucine aminopeptidase; peptidase S; cytosol aminopeptidase; an enzyme that catalyses the hydrolysis of an aminoacyl-peptide to an amino acid and the residual peptide. Its action is most rapid when the N-terminal amino acid is leucine; it liberates other residues at varying rates, and acts poorly at an Xaa-Pro bond. It requires zinc, and is widely distributed in animal tissues, its level in the serum being useful clinically in monitoring hepatobiliary disease processes and placental well-being.

[Leu⁵]enkephalin or **[Leu]enkephalin** *abbr.* for [5-leucine]-enkephalin.

leuk+ a variant form of **leuko+** (before a vowel).

leukemia or (*esp. Brit.*) **leukaemia** or (*sometimes*) **leukosis** any of a group of neoplastic diseases of the leukocytes, usually involving increase in the number of leukocytes in the blood. Leukemias are classified according to the type of leukocyte affected and whether the disease is acute or chronic.

leukemia inhibitory factor *abbr.*: LIF; also called **differentiating-stimulating factor** or **differentiation-inducing factor**; a **cytokine** produced by fibroblasts, T cells, and macrophages. It is a monomer of 179 amino acids that maintains the pluripotent phenotype of embryonic stem cells, and potentiates interleukin-3-dependent proliferation of hemopoietic progenitors.

leuko or **leuco** describing the colourless derivative formed reversibly from a coloured substance, often by reduction; e.g. leuko compound, leuko dye.

leuko+ or **leuco+** or (*before a vowel*) **leuk+** or **leuc+** **1** white or

colourless. **2** denoting of, pertaining to, or acting upon a leukocyte or leukocytes.

leukocidal or **leucocidal** describing an agent that kills leukocytes.

leukocidin or **leucocidin** any extracellular bacterial product that can kill leukocytes of certain animal species and that may also be toxic or lytic towards other cell types. Leukocidins are produced by pathogenic strains of *Staphylococcus* and *Streptococcus*.

leukocyte any white blood cell, i.e. one not containing an oxygen-transporting pigment such as hemoglobin. Vertebrate leukocytes include the **polymorphonuclear leukocytes**, **lymphocytes**, and **monocytes**; they are distinguished by size, shape, and staining characteristics. —**leukocytic** or **leucocytic** *adj.*

leukocyte adhesion deficiency (*abbr.*: LAD) or **leucocyte adhesion deficiency** a condition of severe leukocytosis and recurrent infections in which leukocytes show defective migration and phagocytosis. **LAD I** is associated with mutations in a locus at 21q22.3 that cause lack of or dysfunction of **integrins** containing the β subunit (also called CD18). **LAD II** is accompanied by unusual facial appearance, short stature, and encephalopathy, and is a form of carbohydrate-deficient glycoprotein syndrome that results from defective import of GDP-fucose into the Golgi body.

leukocytosis or **leucocytosis** a gross increase in the number of leukocytes in the blood. It often occurs as a response to an infection. *See also* **leukemia**.

leukokinin or **leucokinin** a specific cytophilic immunoglobulin G (IgG) that constitutes about 2% of the total IgG. It binds specifically and reversibly to autologous polymorphonuclear leukocytes, causing 2- to 2.5-fold stimulation of their phagocytic activity. A proteinase, **leukokininase**, cleaves from leukokinin a tetrapeptide, **tuftsin**, which is thought to bear all the activity.

leukopenia or **leucopenia** an abnormal decrease or deficiency of leukocytes circulating in the blood. *Also (esp. Brit.) leukopaenia* or *leucopaenia*.

leukoplast or **leucoplast** or **leukoplastid** or **leucoplastid** any of the colourless **plastids** found in plant cells. They include **aleuroplasts**, **amyloplasts**, and **elaioplasts**. Leukoplasts may develop into **chloroplasts**.

leukopoiesis or **leucopoiesis** the processes by which leukocytes are formed in the body. —**leukopoietic** or **leucopoietic** *adj.*

leukosis or **leucosis 1** a condition in which there is an abnormal proliferation of one or other of the leukocyte-forming tissues. **2** *an alternative name for leukemia*.

leukosulfakinin a sulfated myotropic 11-residue peptide isolated from head extracts of the cockroach. It is a homologue of human gastrin II and cholecystokinin.

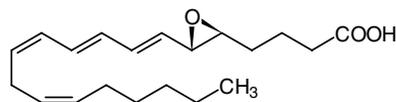

leukotaxin or **leucotaxin** a nitrogen-containing material, found in injured tissue, that when injected into an animal causes increased capillary permeability and migration of leukocytes to the site of injury.

leukotoxin or **leucotoxin 1** any compound toxic to leukocytes. **2** cytochrome P450-derived linoleic acid peroxide; any of a group of substances observed in high concentrations in burned skin samples that may have a bacteriocidal function. **Leukotoxin A** is (12Z)-9,10-epoxyoctadec-12-enoic acid, and **leukotoxin B** is (9Z)-12,13-epoxyoctadec-9-enoic acid (*abbr.*: EpODE) or, its methyl ester (*abbr.*: EpOME).

leukotriene *abbr.*: LT; any member of a family of biologically active substances derived from polyunsaturated fatty acids, notably arachidonic acid, some of which contain a peptide moiety based on cysteine. Leukotrienes are synthesized in response to specific stimuli, are formally derived from eicosanoic acid, and contain a set of three conjugated double bonds (hence 'triene'); one or two additional double bonds, not conjugated to the others, may also be present – a subscript numeral after the abbreviation indicates the total number of double bonds, depending on the polyunsaturated fatty acid from which each is derived, e.g. LTA₄ from arachidonic acid, LTB₅ from eicosapentaenoic acid. They are products of the 5-lipoxygenase pathway. LTC₄ consists of glutathione linked to an eicosanoid; loss of glutamic acid from this leads to LTD₄, and loss of glycine then leads to LTE₄. These three, sometimes collectively known as **peptidoleukotrienes**, are potent spasmogenic agents that make up the active components of **slow-reacting substance of anaphylaxis** (SRS-A).

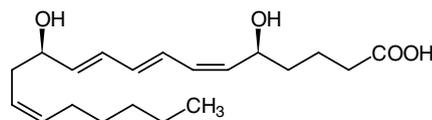

Leukotrienes exert their effects by binding to G-protein-associated membrane receptors. *See also* individual entries below.

leukotriene A *abbr.*: LTA; any of a group of **leukotrienes** characterized as unstable 5,6-epoxides. Leukotriene A₄ (*abbr.*: LTA₄) is (7E,9E,11Z,14Z)-(5S,6S)-5,6-epoxyeicosa-7,9,11,14-tetraen-1-oate. Leukotriene A₃ (*abbr.*: LTA₃) is similar, but lacks the double bond at the C-14, while leukotriene A₅ (*abbr.*: LTA₅) has an additional, 17Z, double bond. LTA₄ is derived from arachidonate via 5-hydroperoxyeicosatetraenoate, and is the precursor either of leukotriene B₄ (*see* **leukotriene B**) by the action of highly specific **leukotriene-A₄ hydrolase** (EC 3.3.2.6), or of **leukotriene C₄** by the action of leukotriene-C₄ synthase (EC 2.5.1.37).

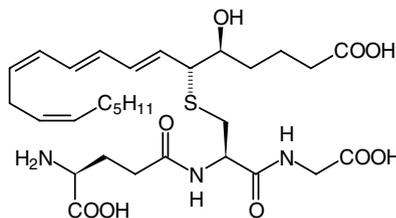

leukotriene A₄

leukotriene-A₄ hydrolase *abbr.*: LTA₄ hydrolase; EC 3.3.2.6; an enzyme that converts (7E,9E,11Z,14Z)-(5S,6S)-5,6-epoxyeicosa-7,9,11,14-tetraenoate (LTA₄) to (6Z,8E,10E,14Z)-(5S,12R)-5,12-dihydroxyeicosa-6,8,10,14-tetraenoate (LTB₄).

leukotriene B *abbr.*: LTB; any of a group of **leukotrienes** characterized as (5S,12R)-5,12-dihydroxy polyunsaturated acids. Leukotriene B₄ (LTB₄) is (6Z,8E,10E,14Z)-(5S,12R)-5,12-dihydroxyeicosa-6,8,10,14-tetraen-1-oate. Leukotriene B₅ (LTB₅) has an additional, 17Z, double bond. LTB₄ is a product of leukotriene-A₄ hydrolase (*see* **leukotriene A**); it is a major product of the 5-lipoxygenase pathway, and is a potent aggregatory, chemokinetic, and chemotactic agent for polymorphonuclear leukocytes (PMNLs) *in vitro* and induces increased vascular permeability and PMNL infiltration *in vivo*.

leukotriene B₄

leukotriene C₄ *abbr.*: LTC₄; a **leukotriene** comprising a glutathione moiety linked through its thio group to C-6 of an eicosanoid. LTC₄ is formed from LTA₄ and glutathione by leukotriene-C₄ synthase (EC 2.5.1.37). It is a potent mediator of smooth muscle contractility, and of vascular tone and permeability, being a potent vasoconstrictor in a variety of vascular beds including the coronary and cerebral circulations. It is the predominant leukotriene in the central nervous system.

leukotriene D₄ *abbr.*: LTD₄; a **leukotriene** comprising a cysteinylglycine moiety linked through its thio group to an eicosanoid moiety. It is a metabolite of **leukotriene C₄** (LTC₄), resulting from the action of membrane-bound γ -glutamyl transferase, which removes glutamic acid. Its actions are similar to those of LTC₄.

leukotriene E₄ *abbr.*: LTE₄; a **leukotriene** comprising a cysteine moiety

ety linked to an eicosanoid moiety. It is derived metabolically from **leukotriene D₄** (LTD₄) by the action of specific membrane-bound dipeptidases, which remove glycine. It has a somewhat longer metabolic half-life than LD₄, but is metabolized to more polar products, notably those in which the terminal methyl group of the eicosanoid moiety is oxidized to a carboxyl group. It activates receptors in human airways and has been implicated in airway hyper-responsiveness in humans.

leukovirus or **leucovirus** any tumorigenic **retrovirus**.

leukovorin or **leucovorin** *see* **folinic acid**.

leumorphin an endogenous 29-amino-acid opioid peptide that corresponds to residues 228–256 of preproenkephalin B; the N-terminal 13 residues correspond to rimorphin (dynorphin B), and the N-terminal five to Leu-enkephalin (*see* **enkephalin**).

leupeptin any modified tripeptide protease inhibitor produced by various actinomycetes. Commonly *N*-acetyl-Leu-Leu-argininal is used in the laboratory; other variants have propionyl in place of acetyl, and valine or isoleucine in place of one or both leucines.

Leu-prolide an analogue of **gonadotropin-releasing hormone** in which residues 5 and 10 (glycine and glycylamide) are replaced by D-Leu and ethylamine respectively.

levan a common name for any (2→6)-β-D-fructofuranan; such compounds are produced mostly by bacteria. As in **inulin** each chain terminates in a (1→2)-α-D-glucopyranosyl residue, but it may also contain (2→1)-β branch points.

levansucrase the recommended name for sucrose 1-fructosyl transferase, EC 2.4.1.10; an enzyme that catalyses the reaction:

See also **sucrase** (def. 3).

levarterenol *see* **norepinephrine**.

levigate (*in chemistry*) **1** to grind (something) into a smooth powder or paste. **2** to separate fine from coarse particles by grinding and suspending them in a fluid. —**levigation** *n*.

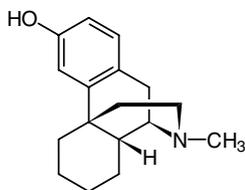

levo- or (*esp. Brit.*) **laevo-** *symbol:* *l-*; a prefix, no longer used, to denote a compound that is **levorotatory**; the levorotatory enantiomer of compound A is now designated as (–)-A.

levo+ or (*before a vowel*) **lev+** *comb. form* denoting on or towards the left. *Also (esp. Brit.) laevo+, laev+.* Compare **dextro+**.

levodopa or (*Brit.*) **laevodopa** (–)-3-hydroxy-L-tyrosine; a naturally occurring amino acid that has been used in the treatment of **Parkinson's disease** easing symptoms such as rigidity, postural problems, and slowness of movement. *See* **3,4-dihydroxyphenylalanine**.

levorotatory or (*esp. Brit.*) **laevorotatory** **1** *symbol:* (–) or (*formerly*) *l-*; describing a chemical compound that rotates the plane of polarization of a transmitted beam of plane-polarized light or other electromagnetic radiation to the left, i.e. in an anticlockwise direction as viewed by the observer looking towards the light source. **2** describing any leftwards or anticlockwise rotation. Compare **dextrorotatory**. —**levorotation** or **laevorotation** *n*.

levorphanol 17-methylmorphinan-3-ol; a synthetic analogue of morphine. It is an orally active analgesic that binds stereospecifically with high affinity to opioid receptors (K_d 10^{–9} M). Five to six times more active than morphine, it is a controlled substance under the US Code of Federal Regulations. **Dextrorphan**, the dextrorotatory form, does not bind to opioid receptors, is not analgesic, but is a very effective antitussive.

levulose or (*esp. Brit.*) **laevulose** an old name, still sometimes used in pharmacy, for D-(–)-fructose, the levorotatory component of invert sugar. Compare **dextrose**.

Lewis acid any chemical species that is able to accept an electron

pair and is thus able to react with a **Lewis base** to form an adduct (i.e. Lewis adduct). For example:

or

i.e.

Lewis acid + Lewis base → Lewis adduct.

[After Gilbert Newton Lewis (1875–1946), US chemist.]

Lewis adduct the adduct formed between a **Lewis acid** and a **Lewis base**.

Lewis antigen *abbr.:* Le antigen; *symbol:* Le; one of the human **blood-group substances**. Lewis specificities are carried on glycosphingolipids and glycoproteins. Primarily a system of soluble antigens in secretions (e.g. saliva) and plasma, the Lewis antigens on red cells are adsorbed passively from plasma, which must be constantly present for them to be maintained. Three Lewis phenotypes are common amongst Caucasians, namely Le(a⁺b[–]), Le(a[–]b⁺), and Le(a[–]b[–]); the very rare Le(a⁺b⁺) is detected in Polynesians and Orientals. The carbohydrate structures providing Le^a and Le^b specificity are shown below; these partial structures are linked through other carbohydrate moieties to a **ceramide**, thus forming a glycosphingolipid, or to a protein, thus forming a glycoprotein.

The structures of the Le^c, Le^d, Le^x, and Le^y determinants are also known. The Lewis antigens are named after a Mrs H. D. G. Lewis, in whom they were first identified. *See also* **galactoside 3(4)-L-fucosyltransferase**.

Lewis base any chemical species that is able to supply an electron pair and is thus able to react with a **Lewis acid** to form an adduct (i.e. Lewis adduct).

Lewis formula or **Lewis structure** a depiction of molecular structure in which the valency electrons are shown as dots so placed that each pair of dots represents two electrons. When placed between two atoms each pair of dots also represents a single covalent bond, whereas dots placed adjacent to only one atom represent the non-bonded outer-shell electrons considered to be associated with that atom alone. (e.g. H:Ḡ:). A double bond is represented by two pairs of dots (e.g. Ḡ:Ḡ:), and so on. Formal charges are attached to atoms as appropriate.

Lewis transferase *see* **galactoside 3(4)-L-fucosyltransferase**.

Lewy body an aggregate of fibrillar ubiquitinated α-synuclein occurring in the substantia nigra in Parkinson's disease. Fibril formation is inhibited *in vitro* by dopamine. [After Frederic H. Lewy (1885–1950), German-born US neurologist.]

lexA a gene in *Escherichia coli* encoding a repressor that regulates the genes induced by **SOS repair**. In the latter, following DNA damage, the *lexA* product, LexA, is hydrolysed by RecA protein (*see* **recA**), thereby allowing the SOS genes to be activated. *lexA* is itself regulated autogenously. LexA binds to operators as a dimer.

Leydig cell a type of steroid-secreting, interstitial cell that occurs in large numbers between the seminiferous tubules of the testis. The cells secrete androgens, especially testosterone, and this activity is stimulated by luteinizing hormone, for which the cells have specific receptors. [After Franz von Leydig (1821–1908), German anatomist and zoologist.]

LFA 1 a leukocyte cell-surface glycoprotein involved in the adhesion of leukocytes to target cells and thus in a variety of immune phenomena, including leukocyte–endothelial cell interaction, cytotoxic T-cell-mediated killing, and antibody-dependent killing by granulocytes and monocytes. It binds to **ICAM**. LFA 1 is a type I membrane glycoprotein belonging to the LEUCAM family of **integrins**; it is a dimer of the α_L and β₂ subunits.

L form (of a bacterium) a defective bacterial cell, of indefinite or spherical shape, in which the cell wall is defective or absent. L forms may develop spontaneously or in response to a variety of stimuli, e.g. thermal or osmotic shock, or the presence of antibiotics that inhibit cell-wall synthesis. They may revert to their original condition

on removal of the stimulus or they may reproduce as L forms. On solid media, L forms have a characteristic colonial appearance resembling that of **mycoplasmas** (with which they were originally confused).

LFS *abbr.* for **Li-Fraumeni syndrome**.

Ig *symbol* for decadic, or common or Briggsian, **logarithms** (alternative to \log_{10}).

LH *abbr.* for luteinizing hormone.

LHC *abbr.* for light-harvesting complex.

LHCP *abbr.* for light-harvesting chlorophyll protein.

LH/FSH-RF *abbr.* for luteinizing hormone/follicle-stimulating hormone releasing factor (i.e. **gonadotropin releasing hormone**).

LHRF or **LH-RF** *abbr.* for luteinizing hormone releasing factor (*see* **gonadotropin-releasing hormone**).

LHRH or **LH-RH** *abbr.* for luteinizing hormone releasing hormone (*see* **gonadotropin releasing hormone**).

Li *symbol* for lithium.

+liberin *word ending* denoting a hypothalamic factor (or hormone) that promotes the release (and perhaps also the biosynthesis) of the particular pituitary hormone indicated; e.g. lulliberin, thyroliberin. *Compare* **+statin**.

library of genes *see* **gene library**.

librate to oscillate about an equilibrium position. —**libration** *n*.

Librium *see* **chlordiazepoxide**.

licensing factor *see* **MCM protein**.

licorice *see* **glycyrrhiza**.

Liddle syndrome a rare autosomal dominant disease characterized by early and severe hypertension, hypokalemic metabolic alkalosis, and decreased secretion of aldosterone. It results from mutations that remove the C-terminal tails of β or γ subunits of **ENaC**. [Named after Grant Liddle, US physician who described it in 1963.]

Liebermann-Burchard reaction the reaction of acetic anhydride in chloroform with unsaturated steroids (e.g. cholesterol) or triterpenes in the presence of concentrated sulfuric acid to produce a blue-green colour. It is used especially in the estimation of cholesterol.

LIF *abbr.* for leukemia inhibitory factor.

life cycle the totality of functional and morphological stages through which any organism passes between any one developmental stage and the identical stage in the next generation. Less commonly it refers to the totality of the various stages through which an individual organism passes between birth and death.

Li-Fraumeni syndrome *abbr.*: LFS; a rare familial predisposition to cancer characterized by presence of a bone or soft-tissue sarcoma before 45 years of age in the proband, and of a cancer or sarcoma in at least one first- or second-degree relative also before the age of 45 years. Germline mutations in the gene for **p53** at 17p13.1 are inherited in an autosomal dominant manner in the majority of LFS families. [After Frederick P. Li and Joseph F. Fraumeni (1933–), US physicians.]

Lig *symbol* for the lignoceroyl group, $\text{CH}_3\text{---}[\text{CH}_2]_{22}\text{---CO}$.

ligancy a less common alternative name for **coordination number**.

ligand 1 (in a simple inorganic compound) any individual atom, group, or molecule that is attached covalently to the characteristic or central atom or moiety. **2** (in an organic compound) any individual atom or chemical group that is attached covalently to a specified carbon atom; *see also* **point ligand**. **3** (in a coordination entity) **a** any individual atom, ion, or molecule that is attached coordinately to one central metal atom (**unidentate ligand**). **b** an ion, molecule, or molecular grouping that has more than one coordinating group (**bi-, tri-, or multidentate ligand**). In both cases the ligand is an electron donor in the formation of one or more coordinate bonds. **4** an ion of either sign that can associate reversibly with one or more (charged or uncharged) atoms or characteristic molecular groupings in another (usually larger) molecule (as in the hydration of a conjugate base, the coordination of a metal cation by a protein, etc.). **5** a molecule (or a class of molecules) that has become linked covalently to another molecule to form a conjugate, whether in a single-step reaction or by stepwise addition of its components (e.g. an oligosaccharide moiety in a glycoprotein). **6** a molecule (or part of one) that is bound or is able to bind selectively and stoichiometrically, whether covalently or not, to one or more specific sites on

another molecule (as in the combination of antigen with antibody, of hormone with receptor, of substrate with enzyme, etc.).

liganded bound by or as a ligand or ligands; ligated; *see* **ligate** (def. 2).

ligand exchange (chromatography) a column-chromatographic technique in which a cation-exchange resin is loaded with a complexable metal ion and the resulting loaded resin, which retains the capability of the metal ion to coordinate to an appropriate complexing agent or ligand, is used for the sorption of that ligand from a solution or a gas phase. Elution is then effected by displacement with, i.e. exchange for, another ligand. The resin is commonly a chelating resin (e.g. a styrene-divinylbenzene copolymer to which iminodiacetate groups are attached) and the ion is usually of a transition metal (e.g. copper or nickel), such ions tending to be bound strongly to these resins. Separation of components of mixtures occurs by virtue of the differences in the stabilities of the various metal-ligand complexes formed.

ligand-field theory (*in inorganic chemistry*) a theory, closely related to the valence-bond theory, that deals with the effects of ligands on the energy levels of the central atom or ion in complexes and crystals. It is especially useful in interpretation of the spectra of inorganic complexes.

ligand-gated describing an ion channel in a cell membrane that is caused to open by the action of an agonist binding to the receptor that governs the channel. Channel opening can be direct, when the receptor acts as an ionophore, or indirect, involving a second messenger regulated by a G-protein.

ligandin a name formerly given to a basic dimeric protein of ~25 kDa per dimeric subunit (*see* **glutathione transferase**). It is abundant in rat and human liver, kidney, and small intestine. It binds with high affinity to heme, bilirubin and other organic anions, polycyclic aromatic carcinogens, and various metabolites. Its presence in the urine, **ligandinuria**, has been used to follow the evolution of various forms of kidney injury, while its presence in serum provides a sensitive indicator in liver injury. Also variously called Y protein, organic anion binding protein, basic azo-dye binding protein, cortisol metabolite binding protein (binder protein I), glutathionetransferase B.

liganding binding by or as a ligand or ligands; ligating; *see* **ligate** (def. 2).

ligandinuria *see* **ligandin**.

ligand-mediated chromatography a variant of **affinity chromatography** that employs an additional component, the affinity ligand, which is a ligand both for the reactive component attached to the insoluble matrix and for the substance to be purified.

ligand-receptor assay a form of **saturation analysis** for a hormone or other agonist wherein the specific binding agent used is an isolated preparation of the naturally occurring cellular receptor substance for the agonist. An advantage of the assay is that the values obtained are considered to be a direct reflection of the biological properties of the substance assayed.

ligase 1 or (*formerly*) **synthetase** the systematic class name for enzymes of class EC 6, all of which catalyse the ligation of molecules of two substances with concomitant breaking of a diphosphate linkage in a nucleoside triphosphate. The recommended names of particular ligases are formed in some instances, especially those of enzymes of subclass EC 6.4, by using the generic name carboxylase, e.g. pyruvate carboxylase, EC 6.4.1.1. In the remaining instances the generic names ligase (def. 2) or synthase are used, according to whether the name of an individual enzyme is to be based on the names of the reactants or on the name of the product, respectively. **2** a generic name for many enzymes of class EC 6 (*see* **ligase** (def. 1)); when added to the names of the two reactants whose ligation is catalysed by a particular enzyme it forms the recommended name of that enzyme; e.g. tyrosine-tRNA ligase (EC 6.1.1.1), acetate-CoA ligase (EC 6.2.1.1). *See also* **synthetase** (def. 2). **3** *see* **DNA ligase**.

ligase chain reaction *abbr.* LCR. a method of detecting single base mutations based on thermal cycling and involving a thermostable DNA ligase. Two contiguous oligonucleotides annealed to a single stranded DNA molecule are ligated if there is perfect complementarity between them and the template. When performed

with two pairs of complementary oligonucleotides, one pair for each strand of the DNA duplex, the ligated oligonucleotides act as templates in the next and subsequent cycles of melting, annealing, and ligation leading to amplification in a manner similar to PCR. The small size of the products makes them suitable for rapid analysis by capillary electrophoresis.

ligate 1 to join together, especially with a **ligature**. **2** (*in chemistry*) to join (molecules or molecular fragments) together with a bond; to coordinate. **3** to bind as or to a **ligand** or ligands. **4** (*in surgery*) to tie off (a blood vessel or duct) with a **ligature** so as to occlude. —**ligation** *n.*; **ligatable** *adj.*; **ligative** *adj.*

ligatin a filamentous plasma membrane protein for the attachment of peripheral glycoproteins to the external cell surface. It acts as a trafficking receptor for phosphoglycoproteins, localizing them, after internalization, within endosomes.

light 1 electromagnetic radiation capable of producing a visual sensation in the eye. It comprises wavelengths in the range 380–780 nm (frequencies 385–789 THz), although the term is sometimes loosely extended to include some ultraviolet and infrared radiation in adjacent parts of the spectrum. **2** (*in chemistry*) describing any (especially metallic) element whose density is relatively small (usually <5000 kg m⁻³). **3** (*in physics*) of less than the usual mass. *Compare heavy.*

light band a region of a muscle **sarcomere** that stains less densely in light microscopy and low-magnification electron microscopy relative to the **dark bands**; together, these differentially staining bands give the striated appearance of skeletal muscle. The light bands are relatively isotropic in polarized light; they represent the regions occupied by **thin filaments**. *See also thick filament, Z line.*

light chain 1 or **L chain** or (*formerly*) **B chain** *symbol:* L; the shorter of the two main types of polypeptide chain of an **immunoglobulin** of any class. Of ≈22 kDa (human), each light chain is linked at its C-terminal cysteine residue by a disulfide bond to the constant region of a **heavy chain**. In any given animal species, light chains may be distinguished serologically into two types, κ and λ, which occur in immunoglobulin molecules of every class in proportions that vary only with the species (about 65% κ in the human), and which have different but homologous sequences. The C-terminal half of each type of light chain consists of a **constant region** and the N-terminal half is a **variable region** possibly related to the antibody-combining site. *See also Bence-Jones protein.* **2** any of the four 15–27 kDa polypeptide chains that, with two heavy chains of ≈200 kDa, constitute a molecule of **myosin**.

LightCycler proprietary name for an instrument used for real-time PCR. Monitoring DNA abundance in each cycle is made possible by measuring the intensity of fluorescence yielded by an intercalating dye such as Sybr Green.

light-effect mediator *abbr.:* LEM; any of a number of substances that, following their light-induced reduction, activate some of the enzymes of the Calvin cycle (*see reductive pentose phosphate cycle*) in photosynthesis. Not all of these mediators have been identified, but it is thought that they are cyst(e)ine-containing proteins that become oxidized in the dark and reduced again in the light. An important member of the group is **thioredoxin**.

light-harvesting chlorophyll protein or **light-harvesting chlorophyll-binding protein** *abbr.:* LHCP; a chlorophyll-binding protein that is abundant in green plants, particularly in those grown at low light intensities. It consists of a 25 kDa polypeptide, encoded by a nuclear gene and synthesized in the cytoplasm, to which is bound most of the chlorophyll *b* and xanthophylls, together with some of the chlorophyll *a*. It appears to be capable of transferring the energy of absorbed light photons to both photosystem I and photosystem II. *See also light-harvesting complex.*

light-harvesting complex *abbr.:* LHC; a **thylakoid** membrane complex of chlorophylls *a* and *b* together with chlorophyll *a-b* binding proteins. LHCs contain a number of other proteins, the function of which is speculative, and accessory pigments. The LHCs capture and transfer energy to photosystems I and II, and are regulated by phosphorylation on threonine residues. *See also light-harvesting chlorophyll protein.*

light meromyosin *abbr.:* L meromyosin or LMM; the smaller, 120 kDa, fragment, also called F3 fragment, produced when **myosin**

is subjected to brief treatment with trypsin or certain other peptidases. It contains much of the helical, rod-shaped tail (>90% α helical) and forms large, ordered aggregates at low ionic strength. Light meromyosin has no ATPase activity and cannot bind actin.

light path 1 the path followed by a beam of light when passing through an optical device or a particular part of one. **2** or **path length** the length of such a path.

light pen an input/output device for use with a computer that, when pointed at a spot on a visual display unit, can sense whether or not the spot is illuminated; the output current from the light pen can then be used to control the operations of the computer.

light reactions of photosynthesis or **light phase of photosynthesis** those reactions of **photosynthesis** in higher plants and algae in which light energy is used to generate NADPH and ATP.

light repair *an alternative name for photoreactivation.*

light-scattering a technique used for the determination of the relative molecular mass, M_r , in solution of a macromolecule whose size is large relative to the wavelength of the light used. The value of M_r of the macromolecule can be calculated from the wavelength of the incident light, the angle and intensity of the scattered light, the refractive indices of the solvent and solute, and the concentration of the solute. *See also Rayleigh scattering.*

light strand or **L strand 1** a polynucleotide strand not labelled with heavy isotope. **2** the strand in a naturally occurring polynucleotide duplex that is of a lower density than its complementary strand. *Compare heavy strand.*

light trapping 1 the process of capturing the energy of incident light in a photosynthetic pigment system. **2** the act or process of using focused light in a liquid medium so arranged as to trap phototactic organisms in a restricted part of that medium.

lignan any member of a class of phenylpropanoid dimers in which the phenylpropane units are linked tail-to-tail and thus have a 2,3-dibenzylbutane skeleton (*compare neolignan*). Lignans occur in higher plants, and in humans and other mammals as products of the action of gut flora on dietary lignans of plant origin. Guaiaretic acid is structurally one of the simplest; **podophyllotoxin** and more particularly its semisynthetic derivatives **Etoposide** and **Teniposide** have defined actions in clinical medicine, with antitumour and possibly antiviral actions. *See also lignin.*

lignify to make or become woody; to accumulate or deposit lignin in the cell walls (of plant tissues). —**lignification** *n.*

lignin any random phenylpropanoid polymer formed in higher plants by the dehydrogenative radical polymerization of various 4-hydroxycinnamyl alcohols, in which the residues are joined in differing proportions and by several different linkages, some of which are nonhydrolysable. Lignin is insoluble in water, and occurs in the cell walls of vascular plants (especially of the supporting and conducting tissues), on which it confers strength, rigidity, and resistance to degradation. It is one of the most abundant biopolymers. *See also lignan.*

ligninase an enzyme that catalyses breakdown of lignin using hydrogen peroxide formed from **oxygenases** to cleave carbon–carbon bonds – i.e. **lignin peroxidases**. An example is diarylpropane peroxidase, EC 1.11.1.14; *systematic name:* diarylpropane:oxygen,hydrogen peroxide oxidoreductase (C–C-bond-cleaving); *other name:* ligninase I. It is a hemoprotein that catalyses a reaction between 1,2-bis(3,4-dimethoxyphenyl)propane-1,3-diol and H₂O₂ to form 3,4-dimethoxybenzaldehyde, 1-(3,4-dimethylphenyl)ethane-1,2-diol, and 4H₂O.

lignin peroxidase *see ligninase.*

lignocellulose a covalent adduct of **lignin** and **cellulose**, found in the walls of xylem cells in woody tissues of plants. —**lignocellulosic** *adj., n.*

lignocerate 1 the *trivial name* for tetracosanoate, CH₃–[CH₂]₂₂–COO⁻, the anion derived from lignoceric acid (i.e. tetracosanoic acid), a saturated straight-chain higher fatty acid. **2** any mixture of lignoceric acid and its anion. **3** any salt or ester of lignoceric acid.

lignoceroyl *symbol:* Lig; the *trivial name* for tetracosanoyl, CH₃–[CH₂]₂₂–CO–, the acyl group derived from lignoceric acid (i.e. tetracosanoic acid). It occurs naturally as acylglycerols in peanut and rapeseed oils, and in certain sphingomyelins.

lignoceroyl-CoA synthase *see* long-chain-fatty-acid-CoA ligase.

LIM domain *see* islet-1.

limit (*in mathematics*) a value to which a function or the sum of a series approaches as an independent variable approaches a specified value or infinity.

limit dextrin the highly branched core that remains after exhaustive treatment of amylopectin or glycogen with α - and/or β -amylases. It is formed because these enzymes cannot hydrolyse the (1 \rightarrow 6) glycosidic linkages present.

limit dextrinase *see* α -dextrin endo-1,6- α -glucosidase, oligo-1,6-glucosidase.

limit dextrinosis an alternative name for type III glycogen disease.

limit digest a digest in which no further degradation can occur under the particular conditions adopted.

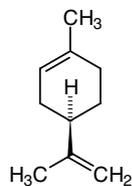

limiting current (*in polarography*) the maximal value of the current reached in circumstances when the steady-state current/potential characteristic has a positive slope.

limiting rate *symbol: V*; the recommended name for the extrapolated rate of an enzyme-catalysed reaction when the enzyme is saturated with substrate(s). It is equal to the product of the stoichiometric concentration of active centres, $[E]_0$, and the catalytic constant, k_0 . It can be determined by a number of methods, including graphical methods such as the **Lineweaver-Burk plot**. *Other names:* maximum rate; maximal rate; maximum velocity; maximal velocity.

limiting viscosity number the recommended name for **intrinsic viscosity**.

LIM kinase *abbr.:* LIMK; a family of protein serine/threonine kinases that contain two N-terminal LIM domains (*see* **islet-1**). They are strongly expressed in neuronal tissues.

limonene *p*-mentha-1,8-diene, a compound that occurs in many essential oils (e.g. oils of lemon, orange, and dill); both enantiomers and the racemic mixture (i.e. dipentene) occur naturally.

(*R*)-(+)-form

LIMS *abbr. for* laboratory information management systems; normally, systems involving automatic electronic data capture and computerized manipulation of data.

lin *symbol for* the linoleoyl group, $\text{CH}_3\text{-(CH}_2\text{)}_3\text{-(CH}_2\text{CH=CH)}_2\text{-(CH}_2\text{)}_7\text{-CO-}$ (*all-Z* isomer).

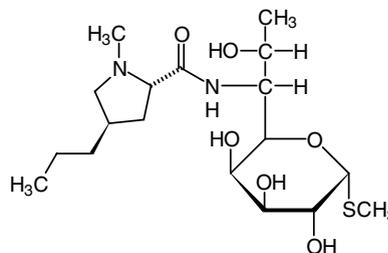

lin3 a gene in *Caenorhabditis elegans* that encodes an **epidermal growth factor**-like type I membrane protein. The protein has two isoforms, produced by alternative splicing, and is essential for vulval development.

lin14 a gene involved in embryonic development in *Caenorhabditis elegans* that codes for a nuclear protein. Regulatory sequences in the 3' untranslated region generate a temporal switch during development. There are three forms of the product: A (537 amino acids); B1 (539 amino acids); and B2 (515 amino acids).

linalool 3,7-dimethyl-1,6-octadien-3-ol; a compound that occurs in linaloe oil and other essential oils; both enantiomers occur naturally. It is used in perfumery.

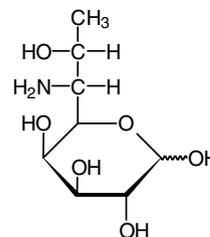

lincomycin an antibiotic produced by *Streptomyces lincolnensis*. It consists of an amide formed between a substituted pyrrolidine-2-carboxylic acid and methyl 1-thio- α -lincosamine. Lincomycin is active mainly against Gram-positive bacteria; it inhibits protein synthesis by interacting with the 50S ribosomal subunit, inhibiting the early steps of peptide bond formation prior to the formation of polysomes.

lincosamides *generic name for* a group of antibiotics structurally related to **lincomycin**.

lincomycin

lincosamine 6-amino-6,8-dideoxy-D-erythro-D-galacto-octose; the carbohydrate component of **lincomycin**.

line 1 (*in spectroscopy*) a very narrow band of frequencies of electromagnetic radiation that is noticeably more intense or less intense than adjacent parts of the spectrum; the image of such a line in a spectrogram. **2** (*in biology*) several generations of a family. *See also* **cell line**, **lineage**. —**lineal** or **linear** *adj.*

LINE *abbr. for* long interspersed nucleotide element (or sequence or repeat); part of the moderately repetitive DNA of mammalian genomes. Any highly repeated DNA sequence interspersed in a mammalian genome and characteristically several kilobases in length. LINES are **retrotransposons** resulting from the action of RNA polymerase II (*see* **RNA polymerase**). Mammalian genomes may contain 10^4 to 10^5 copies of particular LINES. They are regarded as processed **pseudogenes**. The function of LINES is unknown. *Compare* **SINE**. *See also* **Alu sequence**.

lineage lineal descent, especially from a common ancestor.

linear accelerator a device for producing high-energy particles, in which charged particles are accelerated in a straight line along a long evacuated tube by potential differences applied to a series of circular electrodes along the tube.

linear chain a chain of atoms in a molecule, or a chain of residues in a macromolecule, that is neither branched nor covalently closed.

linear correlation any relationship between two variables such that a graphical plot of one variable against the other is a straight line.

linear density gradient a gradient of linearly and continuously increasing density.

linear dichroism the **dichroism** (def. 1) occurring when linearly polarized light is absorbed by a sample containing partially or completely oriented anisotropic molecules.

linear equation any equation containing any number of variables that is of the first degree, i.e. one in which the variables are all raised to the power of one.

linear growth the growth of a culture such that the number of cells (or the cell mass) increases in direct proportion to the duration of growth.

linearity the condition of being in a straight line.

linearize or **linearise** **1** to make linear, i.e. into a straight line. **2** to convert a branched or cyclic form of a (macro)molecule to a linear form, i.e. one with only two ends. —**linearization** or **linearisation** *n.*

linearly polarized or **plane-polarized** describing light (or other electromagnetic radiation) in which the electric vectors of the vibra-

tions all lie in a given plane containing the light beam. See **polarized light**.

line formula a two-dimensional representation of a molecular entity in which atomic symbols are joined by lines representing single bonds, without any indication or implication of stereochemistry.

line immunoelectrophoresis a one-dimensional single **electroimmunodiffusion** technique, useful for the qualitative and quantitative comparison of the antibody spectra of different polyvalent antisera.

line spectrum any spectrum consisting of discrete spectral lines.

Lineweaver–Burk plot a method of plotting enzyme kinetic data. The Michaelis equation is rearranged to give:

$$1/v = K_m/V[S] + 1/V,$$

where K_m is the Michaelis constant, $[S]$ the concentration of the substrate S , v the (initial) rate of reaction at a given value of $[S]$, and V the limiting rate of reaction at infinite $[S]$. If the Michaelis equation holds for the system, a plot of $1/v$ against $1/[S]$ gives a straight line of slope K_m/V , with intercepts on the $1/v$ axis at $1/V$ and on the $1/[S]$ axis at $-1/K_m$. See **Michaelis kinetics**. [After Hans Lineweaver and Dean Burk.]

linewidth the width of a spectral line, usually taken as the distance, in terms of wavelength, frequency, or magnetic flux difference, between the two points of half-peak intensity (half-maximum height).

link (*in chemistry*) an informal term for **bond** (def. 1). See also **linkage** (def. 2).

linkage 1 (*in genetics*) an association of two or more nonallelic genes so that they do not show independent **assortment**; i.e. they tend to be transmitted together usually due to physical association on the same chromosome. **2** (*in chemistry*) an informal term for **bond** (def. 1). See also **link**.

linkage disequilibrium the preferential association of linked genes/DNA markers in a population; i.e. the tendency for some alleles at a locus to be associated with certain alleles at another locus on the same chromosome with frequencies greater than would be expected by chance alone.

linkage group any group of genes whose members show a marked tendency to segregate as a unit. See also **genophore**.

linkage map a map of a chromosome showing in linear order the relative positions of the known genes on that chromosome.

linked genes genes that exhibit **linkage** (def. 1).

linker 1 any small synthetic single-chain oligodeoxynucleotide that is six or more residues long and has a self-complementary base sequence. When self-annealed it forms a stable duplex with blunt ends and containing a **restriction site**. Such linkers are useful for gene splicing. **2** see **cross-link**.

linker DNA see **chromatin, nucleosome**

linking number *symbol*: L ; a topological property of closed circular duplex DNA, defined as the number of turns one strand makes about the other. It must be an integer, and is positive if the turns are right-handed and negative if they are left-handed. It can change only when one or both strands are nicked. It comprises the sum of the **writhing number** (W) and the **twist number** (T), so that a change (ΔL) in the linking number (L) is equal to $\Delta W + \Delta T$.

linoleate 1 the *trivial name* for (*all-Z*)-octadeca-9,12-dienoate, $\text{CH}_3\text{-(CH}_2\text{)}_3\text{-(CH}_2\text{-CH=CH)}_2\text{-(CH}_2\text{)}_7\text{-COO}^-$, (*all-Z* isomer) the anion derived from linoleic acid, (*all-Z*)-octadeca-9,12-dienoic acid, a diunsaturated straight-chain higher fatty acid essential in the diet of mammals. It occurs naturally as acylglycerols in many vegetable oils and in the lipids of many animal tissues. **2** any mixture of free linoleic acid and its anion. **3** any salt or ester of linoleic acid. See also **linoleic family**.

linoleate synthase see **phosphatidylcholine desaturase**.

linoleic family (of polyunsaturated fatty acids) a series of polyenoic acids occurring in mammals, in which the hydrocarbon chain terminates with the alkenyl grouping, $\text{CH}_3\text{-(CH}_2\text{)}_4\text{-CH=CH-}$ (as in linoleic acid; see **linoleate**) and that are synthesized from linoleic acid by chain elongation and/or further desaturation (but which in mammals cannot be synthesized from the corresponding saturated acids or from (9,12,15)-linolenic, oleic, or palmitoleic acids – the latter represent three other series of polyenoic acids). The linoleic family is also known as the $\omega 6$, or $n-6$, family because of the position of the double bond nearest the terminal methyl group. The se-

ries includes (6,9,12)-linolenic acid, eicosa-11,14-dienoic acid, eicosa-5,11,14-trienoic acid, eicosa-8,11,14-trienoic acid, and arachidonic acid.

linolenate 1 or **(9,12,15)-linolenate** or (*formerly*) **α -linolenate** the *alternative trivial names* for (*all-Z*)-octadeca-9,12,15-trienoate; $\text{CH}_3\text{-(CH}_2\text{-CH=CH)}_3\text{-(CH}_2\text{)}_7\text{-COO}^-$ (*all-Z* isomer); the anion derived from (9,12,15)-linolenic acid, (*all-Z*)-octadeca-9,12,15-trienoic acid, a triunsaturated straight-chain higher fatty acid synthesized by plants (notably found in linseed oil) but essential in the diet of mammals (see **linolenic family**). The name equally refers to any mixture of (*all-Z*)-octadeca-9,12,15-trienoic acid and its anion, or any salt or ester of this acid. **2** **(6,9,12)-linolenate** or (*formerly*) **γ -linolenate** the *trivial name* for (*all-Z*)-octadeca-6,9,12-trienoate; $\text{CH}_3\text{-(CH}_2\text{)}_3\text{-(CH}_2\text{-CH=CH)}_3\text{-(CH}_2\text{)}_4\text{-COO}^-$ (*all-Z* isomer); the anion derived from (6,9,12)-linolenic acid (*all-Z*)-octadeca-6,9,12-trienoic acid, a triunsaturated straight-chain higher fatty acid belonging to the **linoleic family**. It occurs naturally as acylglycerols in certain plant-seed oils, especially that of the evening primrose (*Oenothera* spp.), and also in small amounts in the lipids of many animal tissues, especially human breast milk. It is the biosynthetic precursor of arachidonate and the prostaglandins. The name refers equally to any mixture of (*all-Z*)-octadeca-6,9,12-trienoic acid and its anion or any salt or ester of the acid.

linolenic family (of polyunsaturated fatty acids) a series of polyenoic acids occurring in mammals, in which the hydrocarbon chain terminates with the alkenyl grouping $\text{CH}_3\text{-CH}_2\text{-CH=CH-}$ (as in (9,12,15)-linolenic acid; see **linolenate**). The linolenic family is also known as the $\omega 3$ or $n-3$ family because of the position of the terminal double bond three carbon atoms from the methyl end. The longer-chain members can be synthesized in mammals only from dietary (9,12,15)-linolenic acid by chain elongation and/or further desaturation (but not from the corresponding saturated acids or from linoleic, oleic, or palmitoleic acids – the latter represent the other three series of polyenoic acids). If animals are deprived of these fatty acids, certain tissues, such as the eye, retain existing stores of these fatty acids tenaciously, even in offspring of such animals when the restricted diet is continued for more than one generation. Under these conditions, long-chain acids of the **linoleic family**, e.g. (4,7,10,13,16,-)docosapentaenoic (C22:5 $n-6$) acid, are synthesized in appreciable amounts and presumably partially support the function supplied by long-chain $\omega 3$ acids, though the nature of this is unknown. The series includes eicosapentaenoic (C20:5 $\omega 3$) and docosahexaenoic (C22:6 $\omega 3$) acids, which are found in high concentration in fish oils; these $\omega 3$ acids may have value in protecting against heart disease, but in amounts that greatly exceed those needed to fulfil their role as essential fatty acids.

linolenoyl 1 or **(9,12,15)-linolenoyl** or (*formerly*) **α -linolenoyl** *symbol*: αLn or (*sometimes*) Lnn ; the *alternative trivial names* for (*all-Z*)-octadeca-9,12,15-trienoyl; $\text{CH}_3\text{-(CH}_2\text{-CH=CH)}_3\text{-(CH}_2\text{)}_7\text{-CO-}$ (*all-Z* isomer); the acyl group derived from (*all-Z*)-octadeca-9,12,15-trienoic acid. **2** **(6,9,12)-linolenoyl** or (*formerly*) **γ -linolenoyl** *symbol*: γLn ; the *trivial names* for (*all-Z*)-octadeca-6,9,12-trienoyl; $\text{CH}_3\text{-(CH}_2\text{)}_3\text{-(CH}_2\text{-CH=CH)}_3\text{-(CH}_2\text{)}_4\text{-CO-}$ (*all-Z* isomer); the acyl group derived from (*all-Z*)-octadeca-6,9,12-trienoic acid. See **linole-nate**.

linoleoyl *symbol*: Lin ; the *trivial name* for (*all-Z*)-octadeca-9,12-dienoyl; $\text{CH}_3\text{-(CH}_2\text{)}_3\text{-(CH}_2\text{-CH=CH)}_2\text{-(CH}_2\text{)}_7\text{-CO-}$ (*all-Z* isomer); the acyl group derived from linoleic acid. See **linoleate**.

Linux a widely used open-source free operating system similar to UNIX and incorporating UNIX commands and much software from the **GNU** project. The word Linux is constructed in part from the name of the original author, Linus Torvalds, and there is disagreement about the pronunciation of Linux. The original author's family comes from the Swedish-speaking minority in Finland, and Linus is pronounced 'Leenus', of which Linus with a short i (as in 'bit') is the nearest English equivalent. This is favoured by Linus Torvalds himself, but there are those who point out that the name Linus in English has the first syllable sounding like 'line' (e.g. Linus Pauling) and insist on the pronunciation 'line-ux'.

liothyronine a *pharmaceutical name* for L-3,5,3'-triiodothyronine.

lip+ a *variant form of lipo+* (before a vowel).

lipaemia a *variant spelling* (*esp. Brit.*) of **lipemia**.

lipase 1 a general term for any acylglycerol carboxylic ester hydrolase, of EC sub-subclass 3.1.1. The term may be incorporated in the enzyme name as the suffix '+lipase'. **2** *abbr.* (in clinical chemistry): LPS; an alternative name for **triacylglycerol lipase**. See also **hormone-sensitive lipase**, **lipoprotein lipase**, **pancreatic lipase**.

lipemia or **lipidemia** the condition when there is a greater than normal content of lipid in the blood, e.g. after a fatty meal or in certain pathological states. Also (*esp. Brit.*) **lipaemia**, **lipidaemia**.

lipid or (formerly) **lipide** or **lipoid** or **lipin** (**1**) any member of a large and diverse group of oils, fats, and fatlike substances that occur in living organisms and that characteristically are soluble in **lipid solvents** but only sparingly soluble in aqueous solvents. Lipids constitute one of the four major classes of compounds found in living tissues (the others being carbohydrates, proteins, and nucleic acids) and they include: (1) fatty acids; (2) neutral fats (i.e. triacylglycerols), other fatty-acid esters, and soaps; (3) long-chain (or fatty) alcohols and waxes; (4) sphingoids and other long-chain bases; (5) glycolipids, phospholipids, and sphingolipids; and (6) carotenes, polyprenols, sterols (and related compounds), terpenes, and other isoprenoids. See individual entries for details. **2** any oily, fatty, or fatlike material that occurs in living organisms. **3** of, concerned with, for, or relating to **lipid** (def. 2); consisting of or containing **lipid** (def. 1, 2); **lipoid** (def. 1) or lipoidal. —**lipidic** *adj.*

lipid A the glycolipid moiety of bacterial **lipopolysaccharide**.

lipidaemia a variant spelling (*esp. Brit.*) of lipidemia; see **lipemia**.

lipid bilayer any layer, two molecules thick, of amphipathic lipid molecules. If it is surrounded by a polar environment, the polar parts of the lipid molecules are oriented outwards towards the environment and the nonpolar parts inwards into the interior of the bilayer. The two layers of lipid are referred to as **leaflets**, e.g. the inner and outer leaflets of the bilayer. See also **black lipid membrane**.

lipide a variant spelling of **lipid**.

lipidemia an alternative term for **lipemia**.

lipidosis or **lipoidosis** (*pl. lipidoses* or *lipoidoses*) any clinical disorder, also called **lipid storage disease**, that results in the excessive deposition within specific tissues of particular types of lipids. Many lipidoses are inherited disorders of galactosphingolipid metabolism.

lipid raft a type of lipid microdomain in the plasma membrane of cells that sequesters signalling proteins of certain receptors such as those expressed by **T** and **B lymphocytes** that move into the outer leaflet of the **plasma membrane** lipid bilayer. **Caveolae** are a subset of lipid rafts.

lipid-soluble a vague term applied to various classes of nonpolar substances, e.g. sterols, certain vitamins, carotenoids, and polyprenoids, that are commonly present in small amounts in association with the major lipid.

lipid solvent any relatively nonpolar solvent that can be used to extract lipids from tissues or other materials.

lipid storage disease an alternative term for **lipidosis**.

lipid transport protein any of the small proteins that transport lipids and facilitate their exchange between membranes. In plants they are located in the cell wall space and transfer wax and cutin monomers from the plasma membrane to the cell surface.

lipin or **lipine** a former term for **lipid** (def. 1), especially one containing nitrogen and/or phosphorus.

lipo+ or (before a vowel) **lip+** *comb. form* denoting lipid, lipid-containing, or lipid-like.

lipoamide or (sometimes) **lipoyllysine** a **lipoyl** group when in amide linkage to the ϵ -amino group of a specific lysine residue in dihydrolipoamide acetyltransferase (EC 2.3.1.12) and dihydrolipoamide succinyl transferase (EC 2.3.1.61), which form, respectively, parts of the **pyruvate dehydrogenase complex** and the **2-oxoglutarate dehydrogenase complex**.

lipoamide reductase (NADH) EC 1.8.1.4; *recommended name*: dihydrolipoamide dehydrogenase; *other names*: E3 component of α -ketoacid dehydrogenase complexes; lipoyl dehydrogenase; dihydrolipoyl dehydrogenase; diaphorase. An enzyme that catalyses the oxidation by NAD^+ of dihydrolipoamide to form lipoamide and NADH . FAD is a coenzyme. It is typically a homodimer, occurring in the mitochondrial matrix (in eukaryotes), with a redox-active S-S bond similar to glutathione reductase.

lipoate 1 1,2-dithiolane-3-pentanoate, the anion derived from **lipoic acid** (i.e. thioctic acid). **2** any salt or ester of lipoic acid.

lipocaic a substance extractable from the pancreas that was said to be lipotropic in pancreatectomized animals.

lipocalin any of a large group of chiefly extracellular ligand-binding proteins, particularly one that binds hydrophobic ligands, e.g. biliverdin. The family includes retinol-binding protein, α -microglobulin, insect bilin-binding proteins, and **beta lactoglobulin**. The ligand is enclosed by the protein as a flower is enclosed by the calyx (i.e. the sepals), hence the name. Lipocalins have an eight-stranded beta-barrel structure; different ligand-binding properties are determined by loops on the periphery.

lipochrome a former name for any of various lipid-soluble biological pigments.

lipocortin see **annexin**.

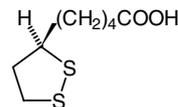

lipofection a lipid-mediated DNA-transfection technique that makes use of unilamellar liposomes that contain a cationic lipid and spontaneously react with DNA.

lipofuscin any of various brownish lipid-soluble pigments that are deposited in animal cells, especially in senility.

lipogenesis the formation of fat. The term is applied especially to the processes by which higher fatty acids are synthesized from non-lipid sources. —**lipogenic** *adj.*

lipogenic amino acid any amino acid that can provide carbon atoms for the biosynthesis of higher fatty acids.

lipoic acid or α -**lipoic acid** *symbol*: Lip(S)₂; 1,2-dithiolane-3-pentanoic acid; thioctic acid; the naturally occurring form is the (*R*)-(+)-enantiomer. Lipoic acid provides the reversibly reducible moiety, **lipoyl**, of **lipoamide** and is a growth factor for certain microorganisms. The reduced form is dihydrolipoic acid, $\text{HS-CH}_2\text{-CH}_2\text{-CH(SH)-[CH}_2\text{]}_4\text{-COOH}$ (*symbol*: Lip(SH)₂); the redox potential of the system is -0.29 V at pH7. Lipoic acid is an essential component of the α -ketoacid dehydrogenase complexes. See **pyruvate dehydrogenase complex**, **2-oxoglutarate dehydrogenase complex**.

lipoid 1 or **lipoidal** being or resembling an oil or a fat; oily, fatty. **2** a former term for **lipid** (def. 1, 2).

lipolysis the breakdown of lipids, especially the (enzymic) hydrolysis of acylglycerols. —**lipolytic** *adj.*

lipolytic hormone an alternative name for **lipotropin**.

lipomodulin or **annexin I** a 40 kDa regulatory protein isolated from rabbit neutrophils that, in its nonphosphorylated form, is an inhibitor of phospholipase A₂ and that on phosphorylation by a cyclic-AMP-dependent protein kinase loses this inhibitory property. It has been suggested that lipomodulin thereby regulates the release of arachidonate from leukocytes, or other cells, that may occur in response to chemoattractants and other external stimuli.

lipophilic tending to dissolve in, having a strong affinity for, or readily mixing with lipids or substances of low polarity. See also **hydrophilic**, **lyophilic**. —**lipophilicity** *n.*

lipophilin another name for myelin proteolipid. See **myelin protein**.

lipophorin any member of the major class of lipid-transporting proteins found in the hemolymph of insects. In locusts, the apoprotein is synthesized in the fat body as an 85 kDa polypeptide. See also **apolipophorin**.

lipophosphoglycans see **GPI anchor**.

lipopolysaccharide *abbr.*: LPS; any of a group of related, 10 kDa, structurally complex components of the outer leaflet of the outer membrane of Gram-negative bacteria. Lipopolysaccharide molecules consist of three covalently linked regions: lipid A, core oligosaccharide, and an O side chain. The innermost layer, lipid A, which is responsible for the toxicity of the lipopolysaccharide, consists of six fatty acyl chains (sometimes hydroxylated) linked in various ways to two glucosamine residues. The branched core

oligosaccharide contains ten saccharide residues, several of them unusual, and has a structure that appears to be similar in closely related bacterial strains. The outermost O side chain, which is highly variable and determines the antigenic specificity of the organism, is made up of many (≈ 50) repeating units of a branched tetrasaccharide containing further unusual sugar residues.

lipopolysaccharide *N*-acetylglucosaminyltransferase EC 2.4.1.56; an enzyme of the lipopolysaccharide core biosynthetic pathway in enteric bacteria; it catalyses a reaction between UDP-*N*-acetyl-D-glucosamine and lipopolysaccharide to form UDP and *N*-acetyl-D-glucosaminyl lipopolysaccharide. *See also* glycolipid.

lipopolysaccharide-binding protein a plasma protein that binds bacterial lipopolysaccharide and is homologous with phospholipid transfer protein and cholesterol ester transfer protein. *See* plasma lipid transfer protein.

lipoprotein any conjugated, water-soluble protein in which the non-protein moiety consists of a lipid or lipids. The lipid may be triacylglycerol, cholesterol, or phospholipid, or a combination of these. *Compare* proteolipid.

lipoprotein(a) one or two molecules of apolipoprotein(a) linked by a disulfide bridge to apolipoprotein B-100; it may be a physiological inhibitor of plasminogen activation. Levels in human plasma (which range from undetectable to 100 mg dL⁻³) show correlation with the incidence of atherosclerosis.

lipoprotein-associated phospholipase A2 or platelet-activating factor acetylhydrolase (*abbr.*: PAF-AH); EC 3.1.1.47; an enzyme that is mainly associated with plasma low-density lipoprotein (LDL) particles and is released by a variety of leukocytes. It catalyses hydrolytic removal of the 2-acetyl moiety of platelet-activating factor (PAF). Deficiency of plasma PAF-AH activity is associated with atherosclerotic occlusive disease in Japan.

lipoprotein lipase EC 3.1.1.34; *abbr.*: LPL; *other names*: clearing factor lipase; diglyceride lipase; diacylglycerol lipase. An enzyme that catalyses the hydrolysis of triacylglycerol to diacylglycerol and fatty-acid anion. Its function, after uptake of dietary lipid, is to hydrolyse triacylglycerols in chylomicrons and very-low-density lipoproteins, to diacylglycerols and fatty-acid anions; the fatty acids are then taken into peripheral tissues for further metabolism; it will also hydrolyse diacylglycerols. It acts in the presence of apolipoprotein C-II on the luminal surface of vascular endothelium. It is a GPI-anchor dimer, and is released by heparin, etc.

lipoprotein signal peptidase *see* preurein-leader peptidase.

liposome **1** a natural lipid globule suspended in the cytoplasm of some cells. **2** any small, roughly spherical, artificial vesicle consisting of a continuous bilayer or multibilayer of complex lipids enclosing some of the suspending medium. Liposomes are formed by allowing complex lipids to 'swell' in aqueous solution sometimes with the aid of sonication. They are used experimentally as models of biological membranes and therapeutically for entrapment of drugs, enzymes, or other agents with a view to their more effective delivery to target cells. Originally, such a structure was termed a cellule (when bilayered), smectic mesophase, spherule, or spherulite. *See also* liquid crystal.

lipotaurine the 7,13-dihydroxy-2-*trans*-octadecenoyl amide of taurine. It is found in the lipid fraction of *Tetrahymena thermophila*.

lipoteichoic acid any of a group of **teichoic acids** that contain lipid, are present in the membranes of all species of Gram-positive bacteria so far examined, and, unlike wall teichoic acids, are extractable with hot water or phenol.

lipotropic or lipotropic tending to prevent the accumulation of, or to remove, abnormal amounts of lipid (in a tissue or organ, e.g. adipose tissue, liver).

lipotropic agent or lipotropic substance any substance capable of preventing or correcting fatty infiltration of the liver caused by choline deficiency.

lipotropic hormone or lipotropic hormone a former name for lipotropin.

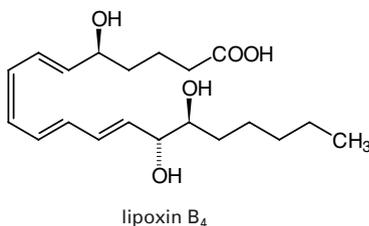

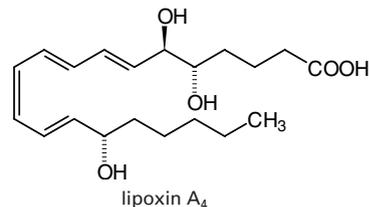

lipotropin or lipotropic hormone (*abbr.*: LPH) either of two polypeptides, β - and γ -lipotropin, of the anterior and intermediary lobes of mammalian pituitary glands, that elicit lipolysis in adipose tissue. β -Lipotropin corresponds in sequence to the 91 C-terminal amino-acid residues of **proopiomelanocortin**, and γ -lipotropin corresponds

to the 58 N-terminal residues of β -lipotropin. In fact, they are of no greater lipotropic potency than corticotropin and α -melanotropin, and whether they have any intrinsic physiological function is still uncertain. Both β - and γ -lipotropins are found in normal human blood. *Other names*: lipolytic hormone; adipokinetic hormone; *former names*: lipotropin; lipotropic hormone.

lipotropism the state or quality of being lipotropic.

lipovitellin a ~ 135 kDa phospholipoprotein that, together with phosvitin, constitutes the bulk of the yolk proteins of the eggs of oviparous vertebrates. These two proteins are synthesized and secreted by the liver as a single large molecule, **vitellogenin**, which is taken up by the ovary and split into the two components.

lipoxin *abbr.*: LX; any of a group of eicosanoids containing a conjugated tetraene structure and having three hydroxyl groups. They are generated by the action of **lipoxygenase** enzymes on polyunsaturated fatty acids (arachidonate and eicosapentaenoate). The major lipoxins, A₄ and B₄, are derived from arachidonate; lipoxin A₄ (LXA₄) is (7*E*,9*E*,11*Z*,13*E*)-(5*S*,6*R*,15*S*)-5,6,15-trihydroxy-eicosa-7,9,11,13-tetraen-1-olate; lipoxin B₄ (LXB₄) is (6*E*,8*Z*,10*E*,12*E*)-(5*S*,14*R*,15*S*)-5,14,15-trihydroxy-eicosa-6,8,10,12-tetraen-1-olate. LXA₄ causes contraction of guinea-pig lung strips, but not ileum; LXA₄ and LXB₄ cause dilation of arterioles.

lipoxygenase **1** EC 1.13.11.12; *systematic name*: linoleate:oxygen 13-oxidoreductase; *other names*: lipoxidase; carotene oxidase. An enzyme that catalyses the oxidation of linoleate to (9*Z*,11*E*)-(13*S*)-13-hydroperoxyoctadeca-9,11-dienoate (*abbr.*: 13(*S*)-HpODE); iron is a cofactor. **2** any dioxygenase enzyme that catalyses the oxidation of polyunsaturated fatty acids to a particular corresponding hydroperoxide. Such enzymes are widely distributed in plants and animals, and occur in leukocytes, mast cells, platelets, and lung, their positional specificities varying from tissue to tissue; notably a 12-lipoxygenase predominates in platelets, and a 5-lipoxygenase in neutrophils. They are important in the conversion of arachidonate to 5- and 12-hydroperoxyeicosatetraenoates (the 5-hydroperoxy compound being the biosynthetic precursor of the leukotrienes). 5-lipoxygenase (EC 1.13.11.34) is important in yielding precursors for **leukotriene** biosynthesis; 15-lipoxygenase (EC 1.13.11.33) yields precursors for the **lipoxins**. All three, however, are involved in the synthesis of hydroperoxy- and dihydroxy-eicosatetraenoates. Compounds that inhibit both lipoxygenase and prostaglandin-endoperoxide synthase include **curcumin**, **eicosate-traynoic acid**, and phenidone (1-phenyl-3-pyrazolidinone). Compounds that selectively inhibit lipoxygenases without inhibiting prostaglandin-endoperoxide synthase include **eicosatriynoic acid** and **esculetin**. *See also* dihydroxyeicosatetraenoate, hydroperoxyeicosatetraenoate, hydroperoxyoctadecadienoate, hydroxyeicosatetraenoate.

lipoyl the acyl group, 1,2-dithiolane-3-pentanoyl, derived from **lipoic acid**. It provides the reversibly reducible moiety of **lipoamide**.

lipoylysine *an alternative name for lipoamide*.

Lip(S₂) *symbol for a residue of (the oxidized form of) lipoic acid*.

Lip(SH)₂ *symbol for a residue of dihydrolipoic acid, the reduced form of lipoic acid*.

lipstatin an irreversible inhibitor of several lipases, e.g. pancreatic, gastric, carboxyl ester, or bile-stimulated lipase of milk, isolated from *Streptomyces toxytricini*. It blocks fat absorption selectively.

lipuria the presence of lipid or oily droplets in the urine.

liquefy or **liquify** to become, or cause to become, liquid. —**liquefaction** or **liquifaction** *n*.

liquid 1 a state of matter, intermediate between a solid and a gas, in which the molecules are relatively free to move with respect to each other but are restricted by intermolecular forces strong enough to prevent spontaneous expansion or significant compression. **2** any substance that is liquid at normal room temperature and pressure. **3** of, pertaining to, being, or behaving as a liquid. *Compare fluid*.

liquid chromatography *abbr.*: LC; any form of **chromatography** in which a liquid is used as the mobile phase.

liquid crystal or **mesomorphic state** or **mesophase** any new phase, resembling both liquid and solid phases, that appears when certain pure liquids are cooled, or pure solids are heated. These new phases have a translucent or cloudy appearance. In liquids of asymmetric molecules the molecular axes are arranged at random. In liquid crystals, however, there is some alignment, which occurs in three main distinguishable modes (certain such mesomorphic substances displaying more than one). In **nematic liquid crystals** the long axes of the molecules are aligned parallel to each other but the molecules are not arranged in layers. These scatter light strongly and appear translucent. In **cholesteric liquid crystals** the molecular axes are aligned and the molecules are arranged in layers but the orientation of the axes changes in a regular way on going from one layer to the next. Because the distance between any two layers with the same molecular orientation is of the order of the wavelength of visible light such crystals display vivid iridescence. **Smectic liquid crystals** are formed by certain molecules that have chemically dissimilar parts, e.g. polar and nonpolar; the chemically similar parts attract one another and the molecules form layers and align themselves in one direction. *See also liquid-crystalline phase*.

liquid-crystal display *abbr.*: LCD; any display of characters or numbers in a calculator, clock, or other device, based on **liquid crystal** cells whose reflectivity is changed by application of an electric field

liquid-crystalline phase any of several types of phase adopted by polar lipids at moderately elevated temperatures. Two major types exist, the lamellar and hexagonal phases. In the lamellar phase, also known as the *L_α* phase, the lipids form sheets of bilayers with the polar groups oriented outwards and the fatty-acyl moieties oriented into the hydrophobic core between the two bilayers. Such a phase is likely to include many such bilayers stacked on top of each other, with their polar groups apposed. In the hexagonal phase, the lipids form a spherical aggregate, in which the polar headgroups may be oriented either into the centre of the sphere, when this is known as the *H₁* phase, or towards the surface of the sphere, the *H₂* phase. In liquid-crystalline phase, the lipid adopts a looser packing, with greater mobility of the fatty-acyl chains than in the crystalline state. At low temperatures, in the absence of water, lipids exist in a crystalline state. If the lipid is heated to a point that attains the **transition temperature**, a temperature characteristic of each pure compound, the lipid undergoes a transition to one of the liquid-crystalline phases. On further heating, it melts completely. Addition of water at low temperature to the crystalline state causes formation of a gel phase, with water layers between the apposed polar headgroups. This gel phase will, on heating to the transition temperature, undergo transition to a liquid-crystalline phase similar to those described above.

liquid-gel chromatography a type of liquid chromatography in which the stationary phase is a gel. It includes **gel-permeation chromatography** and **ion-exchange chromatography**.

liquid glucose *an alternative name for corn syrup*.

liquid-junction potential the electric potential, not experimentally measurable, that arises across the boundary of two solutions of different compositions, e.g. between two half-cells. It is a complex function of the activities and transference numbers of the several ions in the transition layer.

liquid-liquid chromatography *abbr.*: LLC; a type of liquid chromatography in which the stationary phase is a liquid supported on a solid.

liquid medium any liquid **culture medium**.

liquid nitrogen nitrogen in the liquid state. It has a b.p. of -195.79°C (77.36 K), and is useful as a cooling and freezing agent.

liquid oxygen oxygen in the liquid state. It has a b.p. of -182.96°C (90.19 K).

liquid paraffin a colourless, odourless fraction of higher liquid hydrocarbons obtained from petroleum. Light liquid paraffin has a density of $0.83\text{--}0.86\text{ g mL}^{-1}$ and heavy liquid paraffin has a density of $0.86\text{--}0.89\text{ g mL}^{-1}$. It is used for (hot) oil baths, and the purified material is used as a suspending medium in infrared spectroscopy.

liquid-scintillation counting *abbr.*: LSC; a technique for counting particulate radiation. The (radioactive) sample is dissolved or suspended in, or placed in close approximation to, a solvent containing one or more substances that are fluorescent and emit a pulse of light (scintillation) when excited by an incident ionizing particle or photon. The light is detected by photomultipliers, in a liquid-scintillation counter.

liquid-scintillation spectrometry **liquid-scintillation counting** of particulate radiation of one or more selected ranges of energies.

liquid-solid chromatography *abbr.*: LSC; a type of liquid chromatography in which the mobile phase is a liquid and the stationary phase a solid.

liquor 1 (*in pharmacy*) a (usually aqueous) solution of a pure substance. **2** a solution in a chemical manufacturing process. **3** the water used in brewing.

liquorice or (*esp. US*) **licorice** *see glycyrrhiza*.

Lisp *see programming language*. [Acronym from 'list processing']

liter *the US spelling of litre*.

lithiasis (*in pathology*) the presence of calculi (stones), e.g. in the biliary or urinary tracts.

lithium *symbol*: Li; an element of group 1 of the IUPAC **periodic table**; atomic number 3; relative atomic mass 6.939. It is a soft, silvery white, alkali metal of such high reactivity that it must be stored in an inert atmosphere or under oil. It is not found free in nature, occurring in the minerals spodumene and lepidolite. Lithium carbonate, Li_2CO_3 (commonly referred to as 'lithium') is used to control the symptoms of manic-depressive illness. Li^+ inhibits inositol phosphate phosphatase, thereby inhibiting the recycling of inositol, and reducing its availability for phosphatidylinositol synthesis.

lithogenesis (*in pathology*) the processes leading to formation of calculi (stones). —**lithogenic** *adj*.

lithotroph any member of the chemoautotrophs (*see chemotroph*) or **photolithotrophs** that uses CO_2 as a carbon source.

litre or (*US*) **liter** *symbol*: L or l; a non-SI unit of volume, now identical to the cubic decimetre; i.e. $1\text{ L} = 1\text{ dm}^3 = 10^{-3}\text{ m}^3$.

little gastrin *see gastrin*.

liver one of the largest organs of the vertebrate body, situated in the abdominal cavity and formed as a diverticulum of the gut. It is highly vascular; venous blood carrying the products of digestion enters via the hepatic portal vein, while arterial blood enters via the hepatic artery. Blood leaves via the hepatic vein. The liver functions as a gland by secreting **bile** and is an important site of metabolism of carbohydrates, proteins, and fats; it stores carbohydrate as **glycogen**, is active in **gluconeogenesis**, and is important in the regulation of the blood glucose level. It is also an important site for the synthesis of **urea** and **ketone bodies**. The liver synthesizes **fibrinogen**, **prothrombin**, **serum albumin**, and other blood proteins and plays an important part in **detoxication**. The major cells in the liver are the **hepatocytes**. The liver also contains **Kupffer cells** of the reticuloendothelial system, cells derived from the bile duct canaliculae, and fibroblasts, which are particularly important in the pathogenesis of liver cirrhosis. *See also regeneration* (def. 2).

liver X receptor *abbr.*: LXR; *an alternative name for oxysterol receptor*.

livin or **melanoma inhibitor of apoptosis protein** (*abbr.*: ML-IAP); a protein expressed in melanoma cells that inhibits apoptosis. Livin α is not expressed in fetal tissues, whereas livin β is. They bind and inactivate caspases 3, 7, and 9.

LLC *abbr.* for liquid–liquid chromatography.

LLD factor *abbr.* for *Lactobacillus lactis* Dörner factor; a growth factor for this organism, identical to **vitamin B₁₂**.

LLF or **L-L factor** *abbr.* for Laki–Lorand factor, i.e. factor XIII (*see* **blood coagulation**).

lm *symbol for lumen* (def. 1).

L meromyosin *abbr.* for light meromyosin.

LMM *abbr.* for light meromyosin.

ln *symbol for natural, or Napierian, logarithm* (alternative to \log_e).

L-NAME *abbr.* for *N*- ω -nitro-L-arginine methylester; an analogue of L-arginine that is a competitive inhibitor of this amino acid on NO synthase.

LNB-TM7 *abbr.* for long N-terminal of group B transmembrane 7; a subgroup of the G-protein-coupled membrane receptor family. Its members share a stalk region (consisting of $\approx 20\%$ serine and threonine residues) and a characteristic sequence, containing four conserved cysteine residues, that is located immediately N-terminal to the first transmembrane segment. Several members also contain other homology regions in the extracellular region. *See* **Ig-Hepta**.

α **Lnn** or (*sometimes*) **Lnn** *symbol for the linolenoyl or* (9,12,15)-linolenoyl or (*formerly*) α -linolenoyl group; *see* **linolenoyl** (def. 1).

γ **Lnn** *symbol for the* (6,9,12)-linolenoyl or (*formerly*) γ -linolenoyl group; *see* **linolenoyl** (def. 2).

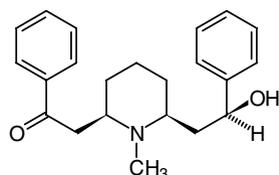

lnRNA *abbr.* for low-molecular-weight nuclear RNA (*see* **small nuclear RNAs**).

load (*in metabolic studies*) the amount (of a specified substance) given in a metabolic test.

loading test or **load test** a metabolic test in which the subject is given a dose of a specific substance and the concentration in blood and/or urine of the substance, or of some related metabolite, is determined as a function of time. Such a test is useful for determining the capacity of a particular metabolic pathway in the subject.

lobelia 1 any plant of the genus *Lobelia*. **2** or **Indian tobacco** the dried leaves, shoot tips, and seeds of *Lobelia inflata*, which contain the alkaloid **lobeline**.

lobeline 2-[6-(β -hydroxyphenethyl)-1-methyl-2-piperidyl]acetophenone; an alkaloid derived from **lobelia** (def. 2) with actions on the central and peripheral nervous systems that resemble those of **nicotine**. It is responsible for some of the properties of herbal cigarettes.

(-)-lobeline

Lobry de Bruyn–van Ekenstein transformation a nonenzymic transformation occurring in carbohydrates, usually in alkaline conditions, that includes epimerization of both aldoses and ketoses and aldose–ketose isomerization. [After Cornelius Adrian Lobry de Bruyn and W. Alberda van Ekenstein (1857–1937), who first described it in 1895.]

local alignment *see* **alignment**.

localized melting the (reversible) destabilization of tertiary structure in a limited region of an ordered biopolymer through interaction with a specific agent, e.g. an enzyme.

local similarity similarity that spans only short regions of a pair or set of aligned sequences (i.e. within a local alignment). *See* **alignment**.

locant a prefix or infix used in organic chemical nomenclature to identify the position of a substituent in a parent structure or of an isotopic modification to a compound. Locants are commonly Ara-

bic numerals, but Greek letters and italicized symbols of heteroatoms are also used. In isotopically modified compounds the italicized name of the function containing the modification may be used if it has no number, e.g. in [*methyl*-¹⁴C]methionine.

loci *the plural of locus*.

lock-and-key model a model for the mechanism of an enzyme–substrate combination, of a hormone–receptor interaction, or of an antibody–antigen reaction. In this model, which is based on the analogy of the complementarity of a lock and its key, one reactant is envisaged binding to the other on a site to which it is structurally complementary.

Locke's solution or **Locke solution** or **Ringer–Locke solution** any one of several balanced salt solutions modified from **Ringer's solution**, initially for the perfusion of mammalian heart and other tissues in physiological experiments. Such solutions have usually contained (in grams per litre, approx.) NaCl (9.0–9.5), KCl (0.20–0.42), CaCl₂ (anhydrous, 0.20–0.24), NaHCO₃ (0.1–0.3), and glucose (1.0–2.5). [After Frank Spiller Locke (1871–1949), British physiologist, who devised them in 1894 and 1900.]

lock-washer structure a putative intermediate structure formed during the assembly of subunits of the coat protein of tobacco mosaic virus into the helically organized structure of the fully formed virion. It is believed to arise after the primary sub-assembly, a two-layered disk with 17 subunits per layer, has self-aggregated into a cylinder; a dislocation in each disk then occurs so that it becomes a two-turn flattened protohelix, of similar shape to a lock washer of the sprung type.

Loco a protein of *Drosophila* that is homologous to the mammalian RGS12, which regulates G-protein signalling via G_{o0} and G_{ai}.

loco disease *see* **locoweed**.

locoweed any of various plants belonging to the genera *Astragalus* or *Oxytropis*, found mainly in western USA. They contain L-2-amino-3-(methylseleno)propionic acid (methylselenocysteine), a nonprotein amino acid, and may cause poisoning (**loco disease**) when ingested by livestock. [From Spanish *loco*, mad.]

locus (*pl.* **loci**) **1** (*in genetics*) the specific position, in all homologous chromosomes, of a particular gene or one of its alleles. **2** (*in mathematics*) the curve or line traced by a point moving so as to satisfy a particular set of conditions.

locus control region *abbr.*: LCR; a group of five regions upstream of the structural genes for the β chain of hemoglobin in human and mouse. These regions are essential for the expression of all the genes of the β -like gene cluster.

lod score *abbr.* for log of the odds score; a statistical test to determine whether a set of linkage data indicates linkage or not, the \log_{10} of the odds favouring linkage. For genetic disorders that are not X-linked, a lod score of +3 (1000:1 odds of linkage) indicates linkage, whilst a score of –2 is odds of 100:1 against linkage.

log 1 *symbol for logarithm*. **2** *abbr.* for logarithmic.

logarithm *abbr. and symbol*: log; the power to which a fixed number (the base) must be raised in order to produce a specified number; i.e. in the expression $a = b^n$, a is the specified number, b is the base, and n is the logarithm. In **decadic** (**common**), or **Briggsian, logarithms** the base is 10; the common logarithm of a is written as $\log_{10}a$, or $\lg a$. In **natural**, or **Napierian, logarithms** the base is e ($= 2.718\ 28\dots$); the natural logarithm of a is written as $\log_e a$ or $\ln a$. In **binary logarithms** the base is 2, and the binary logarithm of a is written as $\log_2 a$ or $\text{lb } a$. In converting between them, $\log_e a = 2.303 \times \log_{10} a$, and $\log_2 a = 3.322 \times \log_{10} a$.

logarithmic or logarithmical *abbr.*: log; **1** of, pertaining to, using, or containing **logarithms** of numbers or variables. **2** describing a relationship in which one variable is proportional to the logarithm of another.

logarithmic growth a type of growth pattern shown by bacteria or other cells in which the number of cells, or the cell mass, increases logarithmically (exponentially) with time. The rate of increase at any time is proportional to the number of cells, or the cell mass, present.

logarithmic phase *abbr.*: log phase; the phase of growth of bacterial or other cells during which they undergo **logarithmic growth**.

logarithmic plot *abbr.*: log plot; a graph in which one axis has a **logarithmic** (def. 1) scale and the other a linear scale.

logical operation an operation on **binary** numbers or statements used in computing and also in applications such as databases and library searches. There are three common binary operators (AND, OR, XOR) and one **unary operator** (NOT).

log-log plot double logarithmic plot; a graph on which both variables are plotted logarithmically.

log-odds score a score calculated as the logarithm of the likelihood of an event relative to its likelihood under a null model. Positive log-odds scores indicate that the event is more likely than it would be under the null model.

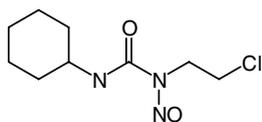

LOH *abbr.* for **loss of heterozygosity**.

Lohmann reaction a name sometimes given to the reversible reaction, catalysed by **creatine kinase**, in which ATP and creatine are formed from ADP and phosphocreatine. [After Karl Lohmann (1898–1978), German biochemist.]

Lohmann's enzyme an alternative name for **creatine kinase**.

lombricine the 2-guanidoethanol phosphoester of phosphoserine. In earthworms, the guanidine group can undergo phosphorylation to phospholombricine, which acts as a **phosphagen**.

lomustine 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea; a chloroethylnitrosourea derivative with actions resembling **carmustine**.

London forces *see* **dispersion forces**.

lone pair or **nonbonding electrons** a pair of electrons of opposite spins occupying the same orbital in the valence shell of an atom.

long-acting thyroid stimulator *abbr.*: LATS; an IgG immunoglobulin found in the serum of a large proportion of thyrotoxic patients. It binds competitively with thyrotropin to thyrotropin receptors in thyroid plasma membrane, stimulates membrane adenylate cyclase, and causes longer-lasting stimulation of thyroid-hormone secretion than thyrotropin itself.

long-chain describing an aliphatic compound of any type with a chain length greater than ten carbon atoms (i.e. C₁₀).

long-chain alcohol or **fatty alcohol** any aliphatic compound with a chain length greater than C₁₀ that possesses a terminal hydroxymethyl group. They are components of **ether lipids**, and esterified with long-chain fatty acids they form wax esters, often major components of plant cuticular waxes.

long-chain-alcohol O-fatty-acyltransferase EC 2.3.1.75; *other name*: wax synthase; an enzyme that catalyses the formation of a long-chain fatty acyl ester, i.e. a wax, from acyl-CoA and a long-chain alcohol with release of CoA.

long-chain base any aliphatic compound with a chain length greater than C₁₀ that possesses a terminal basic group.

long-chain fatty acid any aliphatic compound with a chain length greater than C₁₀ that possesses a terminal carboxyl group.

long-chain-fatty-acid-CoA ligase EC 6.2.1.3; *other names*: acyl-activating enzyme; acyl-CoA synthetase; fatty acid thiokinase (long-chain); lignoceroyl-CoA synthase; an enzyme that catalyses the reaction between ATP and a long-chain carboxylic acid and CoA to form an acyl-CoA with release of AMP and pyrophosphate. It activates free fatty acids formed, e.g., by phospholipase action for further metabolism.

long-chain-3-hydroxyacyl-CoA dehydrogenase EC 1.1.1.211; *other name*: β -hydroxyacyl-CoA dehydrogenase; an enzyme of the **beta-oxidation system** that catalyses the oxidation by NAD⁺ of (S)-3-hydroxyacyl-CoA to 3-oxoacyl-CoA with the formation of NADH. It forms part of a trifunctional protein. *See* **3-hydroxyacyl-CoA dehydrogenase**.

longitudinal relaxation or **spin-lattice relaxation**, a process in magnetic resonance spectroscopy, such as EPR and NMR, that describes the return of the z component of longitudinal (z-) magnetization to its equilibrium value. The characteristic spin-lattice relaxation time is given the symbol T_1 . Its reciprocal is the spin-lattice relaxation rate.

longitudinal relaxation time an alternative name for **spin-lattice relaxation time**.

long-patch repair *see* **short-patch repair**.

long PCR a form of PCR designed for the amplification of DNA molecules of >10kb or longer and using a mixture of proofreading and non-proofreading thermostable DNA polymerases such as Pfu and Taq.

long QT syndrome a syndrome of prolongation of the QT interval on surface electrocardiogram, recurrent fainting, episodic tachyarrhythmia, and sudden (or aborted sudden) death. It is associated with numerous loss-of-function mutations in several genes, including: *SCN5A* (encoding the α subunit of cardiac Na channel); *HERG* (encoding the α subunit of cardiac K channel I_{Kr}); *KCNE1* (encoding the β subunit of cardiac K channel I_{Ks}); and *KVLQT1* (encoding the α subunit of cardiac K channel I_{Ks}). *SCN5A* (at 3p21-p24) encodes a protein of 2016 amino acids containing four regions, each of which has six transmembrane segments. Gain-of-function mutations are associated with idiopathic ventricular tachycardia. *HERG* (for human ether-a-go-go-related gene) is at 7q35-q36 and encodes 1159 amino acids, including six transmembrane segments and extensive intracellular N- and C-terminal domains. *See also* *KCNE1*, *KVLQT1*.

long-range interaction describing an interaction between residues that are situated relatively far apart in a polypeptide or polynucleotide sequence.

long terminal repeat *abbr.*: LTR; a double-stranded DNA sequence, generally several hundred base pairs long, that is repeated at the two ends of the DNA of retroviruses and retrotransposons.

loop 1 the round or oval figure produced by a line, wire, thread, etc. that curves round to cross (or nearly cross) itself. **2** (*in electronics*) any closed electric or magnetic circuit through which a signal can circulate. **3** (*in computing*) any set of instructions in a program that is carried out repeatedly until some specified condition is satisfied.

loopback DNA an alternative name for hairpin DNA; *see* **hairpin**.

loop injector a device for introducing samples into a high-pressure liquid chromatographic column without interruption of the solvent flow to the column. It consists of a loop of metal tubing of small volume, which is filled with the sample; this can then, by an appropriate valve, be flushed by eluent directly onto the column.

loop of Henle or **Henle's loop** the U-shaped part of a nephron lying in the renal medulla. It comprises a thin descending tubule and an ascending tubule formed of both a thin and a thick segment. It plays a role in the selective reabsorption of fluid and solutes. [After Friedrich Gustav Jakob Henle (1809–85), German anatomist and pathologist.]

lophotoxin a cyclic diterpenoid, isolated from Pacific gorgonians (sea fans and whips) of the genus *Lophogorgia*, that irreversibly inactivates the nicotinic acetylcholine receptor on intact BC3H-1 cells.

Lorentz correction factor a correction factor for the effect of solvent polarizability on optical rotation by solutions of proteins or other macromolecules. It is given by: $3/(n^2 + 2)$, where n is the refractive index of the solvent. [After Hendrik Antoon Lorentz (1853–1928).]

Lorentzian lineshape function an equation for the lineshape of a nuclear magnetic resonance absorption signal:

$$g(\omega) = T_2/[1 + (\omega - \omega_0)^2 T_2^2],$$

where $g(\omega)$ is a measure of the intensity of the resonance at a frequency ω , ω_0 is the actual Larmor frequency of the resonating nucleus, and T_2 is the spin-spin relaxation time.

loricrin the major protein of the cornified cell envelope of terminally differentiated epidermal keratinocytes. It is a substrate for transglutaminase, and exists as monomers cross-linked by disulfide and *N*-(γ -glutamyl)lysine isodipeptide bonds.

losartan 2-butyl-4-chloro-1-(*p*-(*O*-1*H*-tetrazol-5-ylphenyl)benzyl)-imidazol-5-methanol; an antihypertensive drug that blocks the binding of angiotensin II (*see* **angiotensin**) to the AT₁ receptor. Affinity for this receptor is much greater than for the AT₂ receptor. It is oxidized by a cytochrome P450 to a carboxylic-acid metabolite that is largely responsible for most of its angiotensin II antagonistic effects.

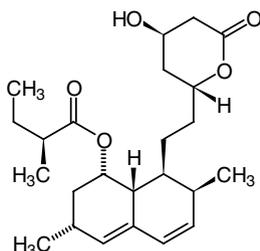

Loschmidt constant *symbol*: N_L ; the number of molecular entities

in unit volume of an ideal gas at 1 atm and 273.15 K. It is equal to the **Avogadro constant** divided by the molar volume, and has the value $2.686\,763 \times 10^{25} \text{ m}^{-3}$. [After Josef Loschmidt (1821–95), Austrian physicist.]

Loschmidt number or **Loschmidt's number** the numerical value of the **Loschmidt constant**.

Loss of heterozygosity *abbr.*: LOH; in genetics, the situation where one of the mutant alleles of an autosomal gene is inherited, and the mutation of the other allele arises by somatic mutation. Cells with the somatic mutation at that locus have lost heterozygosity as they now have two mutant alleles. LOH in tumor suppressor genes such as *RBI* and *p53* is of importance in cancer genetics.

lovastatin or **mevinolin** 6 α -methylcompactin; a metabolite from some fungi (e.g. *Monascus ruber*, *Aspergillus terreus*) that is a potent inhibitor of **hydroxymethylglutaryl-CoA reductase**. It is useful clinically as an antihypercholesterolemic; it reduces plasma levels of total low-density-lipoprotein (LDL), and very-low-density-lipoprotein cholesterol, but it can increase high-density-lipoprotein cholesterol. Its effects result in the induction of up-regulation of LDL receptors on hepatocytes. Two proprietary names are: Mevacor; Mevinacor.

low-complexity region a region in the amino-acid sequence of a protein in which a particular amino acid, or a small number of different amino acids, are enriched. *See*, for example, **leucine zipper**.

low-density lipoprotein *abbr.*: LDL; one of the classes of lipoprotein found in blood plasma in many animals (data normally relate to humans). LDLs are also known as β lipoproteins, owing to their electrophoretic mobility intermediate between high-density or α lipoprotein, and the origin. LDL particles have diameter 19.6–22.7 nm, solvent density for isolation (g mL^{-1}) 1.019–1.063, hydrated density (g mL^{-1}) 1.034. Their approximate composition (% by weight) is 13% unesterified cholesterol, 39% esterified cholesterol, 17% phospholipid, 11% triacylglycerol, 20% protein. Their apolipoprotein composition (% by weight total apolipoprotein) is 98% B-100, with traces of different C and E apolipoproteins. They are synthesized in plasma from very-low-density lipoproteins and intermediate density lipoproteins through the action of lipoprotein lipase; they transport cholesterol to peripheral tissues. They have the highest content of cholesterol of any plasma lipoprotein, and have been linked to the incidence of coronary heart disease in epidemiological studies. *See also* **apolipoprotein** (for individual apolipoproteins) and **LDL receptor**.

low-density-lipoprotein receptor *see* **LDL receptor**.

low-energy compound a name sometimes applied improperly to certain compounds that undergo reaction leading to release or transfer of, e.g., phosphate, where the standard free energy change for the hydrolysis of the bond is $<20 \text{ kJ mol}^{-1}$. It is used especially in making a distinction from a **high-energy compound**. The use of the term does not meet the highest standards of thermodynamic correctness.

low-lipid lipoprotein (*sometimes*) an alternative name for **high-density lipoprotein**.

Lowry method a colorimetric method for the estimation of small amounts (down to 10 μg) of protein. It is a combination of the **biuret reaction** for peptide bonds and the colour formed by reaction of **Folin–Ciocalteu reagent** with tyrosine and tryptophan residues in the protein. [After Oliver Howe Lowry (1910–1996), US pharmacologist and biochemist.]

low-spin complex any of the ligand complexes of transition-metal ions having a maximal number of paired *d*- or *f*-shell electrons in

the lower energy levels. This state occurs when the pairing energy is less than the crystal-field splitting energy. *Compare* **high-spin complex**.

Lozenge a protein of *Drosophila* that is involved in the determination of photoreceptor identity during eye development. Its DNA-binding domain is homologous with that of Runt (of *Drosophila*) and AML1 (of human).

LPG *abbr.* for lipophosphoglycan (*see* **GPI anchor**).

LPH *abbr.* for lipotropic hormone (i.e. **lipotropin**).

LPL *abbr.* for lipoprotein lipase.

L protein *see* **glycine cleavage enzyme**.

LPS *abbr.* for 1 lipopolysaccharide. 2 lipase (def. 2).

LPS-binding protein *see* **BPI protein**.

Lr *symbol* for lawrencium.

L region any region in a (carcinogenic) polycyclic aromatic hydrocarbon that consists of two *para*-carbon atoms, e.g. the *meso*-9,10-carbon atoms of anthracene, which display the highest free-valence indices. The lack of such a region has been suggested to correlate with a lack of carcinogenicity of some hydrocarbons. *Compare* **K region**.

LRF *abbr.* for luteinizing hormone releasing factor (*see* **gonadotropin-releasing hormone**).

LRH *abbr.* for luteinizing hormone releasing hormone (*see* **gonadotropin-releasing hormone**).

LRP *abbr.* for LDL receptor-related protein; *other names*: apoE/ α_2 -macroglobulin receptor; E/ α_2 -M receptor. A multifunctional plasma membrane receptor primarily of hepatocytes. It is a transmembrane protein of 4525 residues that is homologous to **LDL receptor**. Its extracellular domain contains 31 cysteine-rich repeats and 22 EGF repeats (versus 7 and 3, respectively, in LDL receptor). It binds chylomicron remnants, hepatic lipase, α_2 -macroglobulin, plasminogen activator-inhibitor complexes, lactoferrin, and *Pseudomonas* exotoxin A. *See also* **LRP2**.

LRP2 *abbr.* for LDL receptor-related protein 2; *other names*: megalin; gp330; Haymann nephritis antigen. A large transmembrane glycoprotein of 4635 residues that is homologous with LRP and binds most of the latter's ligands. It is abundant in renal glomeruli and proximal tubules but also occurs in other tissues. It appears to be a drug receptor that mediates uptake of aminoglycosides, polymyxin B, and gentamicin. *See also* **LRP**.

LRr *abbr.* for leucine-rich repeat.

LSC *abbr.* for 1 liquid-scintillation counting. 2 liquid-solid chromatography.

LSD *abbr.* for lysergic acid diethylamide; *see* **lysergic acid**.

L7/L12 site a component of EF-Tu translocase (*see* **EF-T**) activity involving in bacteria the **ribosomal proteins** L7 and L12.

L strand *abbr.* for light strand.

LT *abbr.* for 1 leukotriene; the subtype may be indicated by a third letter, as in LTA (leukotriene A). 2 lymphotoxin.

LTQ *abbr.* for lysine tyrosylquinone; a quinone cofactor derived by post-translational linking of a lysine residue with a topaquinone in some quinoproteins. It is the cofactor of lysyl oxidase.

LTR *abbr.* for long terminal repeat.

LTRPC *abbr.* for long transient receptor potential channel. *See* **TRP channel**.

LTRPC2 *see* **TRP channel**.

LTRPC7 *see* **TRP channel**.

L-type pentose pathway *see* **pentose phosphate pathway**.

Lu *symbol* for lutetium.

Lubrol a proprietary name for a polyoxyethylene nonionic detergent; the structure of Lubrol PX is the same as C_{12}E_9 (*see* **C_xE_y**). It is useful for solubilizing membrane-bound enzymes such as adenylate cyclase.

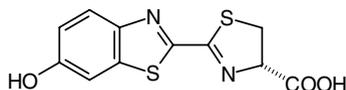

LUCA *abbr.* for last universal common ancestor.

LUCA 15 a multidomain RNA-binding protein that is generally conserved in eukaryotes and is deleted in certain human lung cancers. It contains two N-terminal RNA-recognition sequences, a C2H2 zinc finger, and a C-terminal glycine-rich sequence. The rat homologue is associated with hnRNPs.

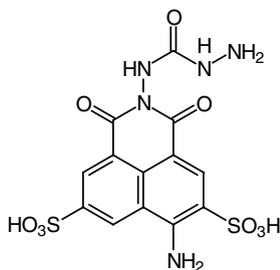

luciferase any member of a group of monooxygenase enzymes that catalyse bioluminescent reactions. **Firefly luciferase** (EC 1.13.12.7; *recommended name*: *Photinus* luciferin 4-monoxygenase (ATP hydrolysing)) occurs in the lantern of the American firefly, *Photinus pyralis*, and may be used with firefly **luciferin** for estimation of low

concentrations (10^{-6} – 10^{-10} mol L⁻¹) of ATP. It catalyses a reaction between *Photinus* luciferin, O₂, and ATP to form oxidized *Photinus* luciferin, CO₂, H₂O, AMP, pyrophosphate, and *hν*; magnesium is a cofactor. It covalently binds the adenylyl group (AMP) after reaction with ATP and release of pyrophosphate. It is a peroxisomal enzyme. **Renilla luciferase** (EC 1.13.12.5; *recommended name*: *Renilla* luciferin:oxygen 2-oxidoreductase (decarboxylating)) occurs in the sea pansy *Renilla reniformis* and catalyses the reaction between *Renilla* luciferin (2,8-dibenzyl-6-(4-hydroxyphenyl)imidazo[1,2-*a*]pyrazin-3(7*H*)-one) and O₂ to form oxidized *Renilla* luciferin, CO₂, and *hν*. Luciferin is bound to a luciferin-binding protein (BPLH2). Bioluminescence is triggered by calcium ions, and the excited state transfers energy to an accessory protein, *Renilla* green fluorescent protein, which emits green light. **Bacterial luciferase** (EC 1.14.14.3; *recommended name*: alkanal monooxygenase (FMN-linked)) occurs in *Photobacterium fischeri* and catalyses a reaction between RCHO, reduced FMN, and O₂ to form RCOOH, FMN, H₂O, and *hν*. It may be used together with NAD(P)H dehydrogenase (FMN), EC 1.6.8.1, from luminescent bacteria for estimation of low concentrations (10^{-7} – 10^{-9} mol L⁻¹) of NAD(P)H. *See also* **lux proteins**.

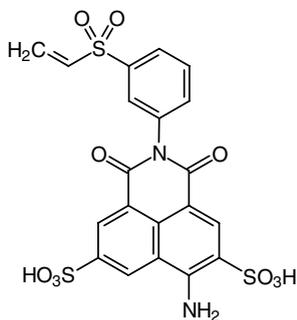

Luciferin any bioluminescent substance that is a substrate for a **luciferase** enzyme. Luciferins from different sources often bear no structural resemblance to one another. Firefly luciferin, obtained from the lantern of the American firefly, *Photinus pyralis*, is D-(–)-4,5-dihydro-2-(6-hydroxy-2-benzothiazoloyl)-4-thiazolecarboxylic acid.

Lucifer Yellow one of several dyes based on the structure 6-amino-2,3-dihydro-1,3-dioxo-benz[*d,e*]isoquinoline-5,8-disulfonic acid. Lucifer Yellow CH has been used as a marker for movement between cells, and for ultrastructure tracing; Lucifer Yellow VS covalently labels proteins rapidly under mild conditions.

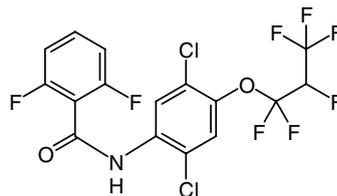

Lucifer Yellow CH

Lucifer Yellow VS

Lucite a proprietary name for poly(methyl methacrylate).

lufenuron *N*-[2,5-dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)-phenylaminocarbonyl]-2,6-difluorobenzamide; an inhibitor of insect development, used as a once-per-month pill to control flea populations on domestic dogs, by inhibiting egg development.

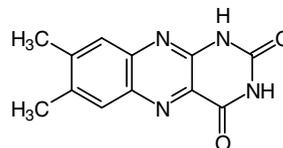

luffin a type I ribosome-inactivating protein.

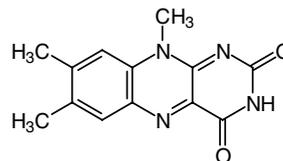

luliberin the *recommended name* for a hypothalamic decapeptide amide now known to be identical with **gonadotropin-releasing hormone**.

lumen 1 (*pl. lumens*) *symbol*: lm; the SI derived unit of **luminous flux**, equal to the quantity of visible electromagnetic radiation emitted per second in a cone of unit solid angle (one steradian, sr) by a uniform point source of unit luminous intensity (one candela, cd); i.e. 1 lm = 1 cd sr. **2** (*pl. lumina*) the cavity or passageway of a tubular organ, such as a blood vessel, duct, or length of gut. **3** the volume enclosed within the membranes of a mitochondrion or of the endoplasmic reticulum, or of microsomes prepared from cells. **4** the space enclosed by the walls of a plant cell that no longer contains a protoplast. **5** the bore of a catheter, hollow needle, or other tubular device. —**luminal** *adj.*

lumichrome 7,8-dimethylalloxazine; a compound showing a blue fluorescence, formed by the photolysis of riboflavin in acid or neutral solution.

lumiflavin 7,8,10-trimethylisoalloxazine; a compound showing a yellow-green fluorescence, formed by the photolysis of riboflavin in alkaline solution.

lumigenic substrate any substrate capable of emitting light when acted on by an appropriate enzyme.

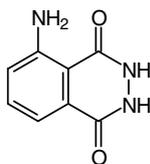

lumina the plural of **lumen** (def. 2).

luminal protein or (*sometimes*) **ER-resident protein** any protein that is retained within the cisternae of the **rough endoplasmic reticulum**, e.g. protein disulfide isomerase. Such proteins possess at their C terminus the tetrapeptide sequence Lys-Asp-Glu-Leu (**KDEL**) in animal cells and His-Asp-Glu-Leu (**HDEL**) in yeast. The proteins move to the Golgi and are returned to the endoplasmic reticulum.

luminescence the production of visible light by any mechanism that does not depend upon the system having a temperature appreciably above the ambient. It comprises **fluorescence** and **phosphorescence**. —**luminescent** *adj.*

luminogenic 1 producing **luminescence**. **2** of or pertaining to a non-luminescent material that can be acted on by an enzyme to produce a luminescent substance.

luminol 5-amino-2,3-dihydro-1,4-phthalazinedione; a substance useful in the detection or determination of trace amounts of oxidizing agents by virtue of the intense bluish luminescence it emits on oxidation in alkaline solution.

luminometer an instrument for measuring **luminescence**. Given appropriate conditions, it may be used also to measure the concentrations of enzymes, substrates, etc. that participate in, or can be coupled to, light-producing reactions.

luminometry the measurement of **luminescence** with a luminometer. —**luminometric adj.**

luminophore 1 any luminescent substance, whether a fluor or a phosphor. **2** a molecular grouping responsible, or thought to be responsible, for the **luminescence** of a larger molecule; a luminescent chromophore.

luminous 1 emitting visible light; bright, shining. **2** (*in photometry*) (of a physical quantity relating to light) evaluated by the visual sensation of brightness to the eye of an observer rather than by an absolute measurement of radiant energy.

luminous flux *symbol:* Φ_v or Φ or P_v or P ; a measure of the rate of flow of radiant energy within the visible region of the electromagnetic spectrum. The SI derived physical quantity is the arithmetic product of the **luminous intensity** of a source of visible light and the solid angle, expressed in steradians, into which the light is emitted. The SI derived unit of luminous flux is the **lumen** (def. 1).

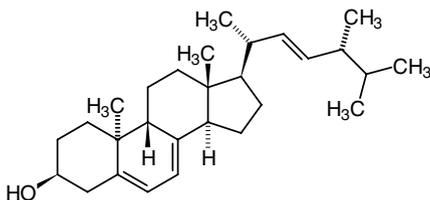

luminous flux density the **luminous flux** per unit cross-sectional area of a beam of light.

luminous intensity *symbol:* I_v or I ; one of the seven SI base physical quantities, defined as the amount of visible light emitted per second per steradian by a point source in a given direction. The SI base unit of luminous intensity is the **candela**.

lumirhodopsin an intermediate in the light-induced modification of **rhodopsin** prior to its breakdown into opsin and all-*trans*-retinal. It has an absorption maximum at 497 nm.

lumisome a membrane-bound particle, ≈ 200 nm in diameter and present in homogenates of various species of luminescent marine coelenterates, that contains all the proteins necessary for the production of the typical green bioluminescence observable *in vivo*. It is probably the cytoplasmic organelle responsible for emission of light by such organisms.

lumisterol 9 β ,10 α -ergosta-5,7,22-trien-3 β -ol; a compound produced by the UV irradiation of **ergosterol**, from which it differs in the spatial arrangement of the methyl group at C-10.

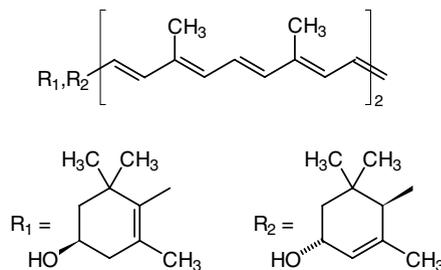

Lundh test a test for pancreatic function in which the pancreas is stimulated by a test meal (corn oil, milk powder, and glucose), after which trypsin activity is measured in duodenal juice.

lupus erythematosus an autoimmune disease characterized by recurrent red patches on the skin, usually accompanied by episodes of inflammation of joints, tendons, and other connective tissues and organs. Antinuclear and various other antibodies are usually present in serum.

luteal of, relating to, or characterized by the development of a corpus luteum or corpora lutea.

luteal phase *see* **estrous cycle**.

lutein 3,3'-dihydroxy- α -carotene, one of the most widespread naturally occurring xanthophylls (i.e. carotene alcohols; *see* **carotenoid**), found in many higher plants, some algae, egg yolk, and corpora lutea. It is an antioxidant.

luteinize or **luteinise** to cause the formation of corpora lutea in; to undergo transformation into a corpus luteum. —**luteinization** or **luteinisation n.**

luteinizing hormone or **luteinising hormone** *abbr.:* LH; *recommended name:* lutropin; *former name:* interstitial cell-stimulating hormone (*abbr.:* ICSH). One of the two gonadotropic **glycoprotein hormones** secreted by the anterior pituitary. The human hormone (28.5 kDa) consists of an α subunit that is almost identical to that of other glycoprotein hormones, and a β subunit that confers hormonal specificity; the carbohydrate content is 15.5%. In the female it promotes ovulation and luteinization of the ovarian follicle, where it stimulates the conversion of progesterone to pregnenolone, thereby increasing the formation of further progesterone. In the male it stimulates testicular interstitial (Leydig) cell function by promoting the production of androgens, especially testosterone. LH binds to a G-protein-associated membrane receptor. Mutations in the receptor lead to hypogonadism or to precocious puberty in males. Mutations in the β subunit of LH also lead to hypogonadism in males.

luteinizing hormone/follicle-stimulating hormone releasing factor *abbr.:* LH/FSH-RF *see* **gonadotropin-releasing hormone**.

luteinizing hormone releasing factor *abbr.:* LHRF *see* **gonadotropin-releasing hormone**.

luteinizing hormone releasing hormone *abbr.:* LHRH or LH-RH or LRH; *see* **gonadotropin-releasing hormone**.

luteo+ *comb. form* indicating 1 yellow. **2** of the **corpus luteum**.

luteolin a flavone that is present in alfalfa and induces *nod* gene expression in some *Rhizobium* species.

luteolysin an alternative name for **prostaglandin F_{2 α}** .

luteolysis degeneration or regression of the **corpus luteum**. —**luteolytic adj.**

luteotropic hormone or **luteotrophic hormone** *abbr.:* LTH; a former name for **prolactin**.

luteotropin or **luteotrophin** a former name for **prolactin**.

lutropin the recommended name for **luteinizing hormone**.

lutropin receptor a G-protein-coupled membrane receptor that mediates the effects of lutropin via activation of adenylate cyclase. It has a long extracellular N-terminal region (≈ 340 amino acids) that is glycosylated.

lux *symbol:* lx; the SI derived unit of illuminance, equal to 1 lumen per square metre; i.e. $1 \text{ lx} = 1 \text{ lm m}^{-2}$.

Lux proteins the counterpart in marine bacteria of the **luciferase** system. They mediate bioluminescence, and are products of genes regulated by the *lux* operon. In *Vibrio* spp., LuxA (catalytic subunit) and LuxB constitute bacterial luciferase (EC 1.14.14.3); it catalyses a reaction between reduced FMN, RCHO, and O₂ to form FMN, RCOOH, H₂O, and *h ν* . LuxC is an **acyl-CoA reductase** required to form the 'RCHO' above. LuxD is an acyl transferase component of the fatty acid reductase system required for aldehyde biosynthesis (EC 2.3.1.-). LuxE is an acyl-protein synthetase (EC 6.2.1.19) that

activates tetradecanoic acid. LuxG is the flavin reductase. LuxI and LuxJ are part of the regulatory system; they are required for the synthesis of OHHL (*N*-(3-oxohexanoyl)-L-homoserine lactone), an autoinducer molecule that binds to LuxR. LuxR is the transcriptional activator.

LVP *abbr.* for lysine vasopressin.

LW antigen *abbr.* for Landsteiner–Weiner antigen. *See* Rhesus factor.

lx *symbol* for lux.

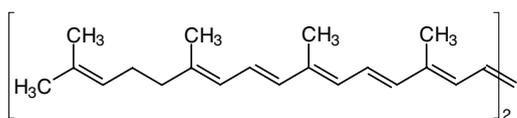

LX *abbr.* for lipoxin.

LXR *abbr.* for liver X receptor. *See* oxysterol receptor.

lyase 1 the systematic name for any enzyme of EC class 4 that catalyses the cleavage of C–C, C–O, C–N, and other bonds, leaving double bonds, or conversely adding a group to a double bond. **2** 17,20-lyase the common name for 17 α -hydroxyprogesterone aldolase (EC 4.1.2.30).

lyate ion the anion produced by the autoprotolysis of a protogenic solvent; e.g. the hydroxide ion is the lyate ion of water.

lycopene the characteristic red pigment of tomatoes and some other ripe fruit. It is an acyclic carotenoid, and the biosynthetic precursor of the cyclic carotenes in plants.

lycopodium 1 any clubmoss of the genus *Lycopodium*. **2** the spores of various clubmosses, e.g. *L. clavatum*. They are used as a covering for pills and suppositories, in pyrotechnics, and in foundry work.

lymph 1 the pale-yellow, clear, or cloudy fluid that is contained within the vessels of the lymphatic system. It contains a little protein, and derives from the interstitial fluid, which is drained by the lymphatic vessels and ultimately discharged into the bloodstream, e.g. via the thoracic duct. The composition of lymph varies in different parts of the body, that from the liver and intestine containing more protein, and the latter more fat in the form of chylomicrons. Lymph also contains varying numbers of cells, mostly small lymphocytes, and coagulation factors. **2** the exudation from a sore.

lymphatic 1 of, pertaining to, or containing lymph; of or pertaining to the lymphatic system. **2** a lymphatic vessel.

lymphatic system the extensive network of capillary-like lymphatic vessels in vertebrates that convey the lymph from the peripheral tissues to the venous system. **Lymph nodes** occur at various points along the vessels.

lymph node or **lymph gland** any of numerous small swellings distributed throughout the lymphatic system of vertebrates. Each node consists largely of lymphocytes, together with macrophages and dendritic cells held together in a loose reticulum. Lymph nodes receive lymph from the peripheral tissues via afferent lymphatic vessels and pass it on via efferent vessels to more centrally placed lymph nodes, and ultimately to the thoracic duct. The lymph nodes act as filters through which the lymph must pass and where foreign material comes into intimate contact with macrophages and lymphocytes. They are active centres for phagocytosis and the site of initiation of humoral and cell-mediated immune reactions.

lympho+ or (before a vowel) **lymph+** *comb. form* indicating lymph or the lymphatic system.

lymphoblast any blast cell of the lymphoid cell series. —**lymphoblastic** *adj.*

lymphocyte a type of leukocyte found in vertebrates and having various functions in specific immunity. It is a spherical cell, 7–12 μ m in diameter, with a large, round nucleus, often indented when seen by electron microscopy, and scanty cytoplasm containing scattered ribosomes but little endoplasmic reticulum and few other organelles. Lymphocytes occur in lymph nodes, other tissues, lymph, and blood, and they circulate between these tissues. Mature, differentiated lymphocytes comprise two main classes, **B lymphocytes** and **T lymphocytes**. Lymphocytes without the characteristics of either of these classes are termed **null lymphocytes**.

lymphocyte-activating factor *abbr.*: LAF; *an alternative name for interleukin 1.*

lymphocyte-specific protein-tyrosine kinase *see* Lck.

lymphocyte transformation *see* transformation (def. 3).

lymphocytosis an abnormal increase in the number of lymphocytes, especially in blood.

lymphoid of or resembling lymph, or lymphatic tissue.

lymphoid cell series a cell series comprising all cells that morphologically resemble lymphocytes, their precursors (e.g. lymphoblasts), and cells that may be derived from them (e.g. plasma cells).

lymphoid tissue any vertebrate tissue that is made up predominantly of lymphocytes, e.g. lymph, lymph nodes, spleen, thymus, Peyer's patches, adenoids, pharyngeal tonsils, and, in birds, bursa of Fabricius and cecal tonsils.

lymphokine any soluble nonimmunoglobulin released by primed lymphocytes on a second interaction with the specific activator (which may be a soluble antigen, a cell-associated antigen, or a mitogen). They modulate cell-mediated immunity by modulating the behaviour of other types of cell within the same organism (e.g. macrophages, polymorphonuclear leukocytes), and are recognized as a subgroup of the cytokines. Specific lymphokines include: chemotactic factor for macrophages, lymphotactin, lymphotoxin (i.e. tumour necrosis factor β), macrophage-activating factor (MAF), macrophage migration enhancement factor, macrophage migration inhibitory factor (MIF), (antigen-independent) mitogenic factor, skin-reactive factor, and transfer factor. Lymphokines that can act between different populations of leukocytes are known also as interleukins. *See also* colony-stimulating factor.

lymphoma any malignant tumour, or condition allied to a tumour, arising from some or all of the cells of lymphoid tissue. The term includes lymphatic leukemias, Hodgkin's disease, and reticulososes.

lymphoreticular tissue *an old general term* for tissues consisting largely of lymphocytes and macrophages.

lymphotoxin *abbr.*: LT; *an alternative name for tumour necrosis factor β ; see also lymphokine.*

lyn a protooncogene encoding a tyrosine kinase belonging to the src family.

lynx a very powerful free open-source text-only browser originally designed for use with character-cell, nongraphics terminals but of great value in rapid access to HTML pages and for checking such pages for compliance with guidelines for visually impaired users.

lyo+ *comb. form* indicating looseness, dispersion, or dissolution.

lyochrome a former name for flavin.

lyocytosis cell lysis by extracellular digestion, e.g. during insect metamorphosis.

lyoenzyme *an old term* for any enzyme existing in the cell in soluble form.

lyoglycogen *an old name* for the fraction of a sample of glycogen that is extractable by water on a steam bath.

lyolysis *an alternative term for solvolysis.*

Lyon hypothesis (*in genetics*) the hypothesis that gene dosage compensation in mammals is accomplished by random inactivation of one of the two X chromosomes in all somatic cells of females. The first inactivation occurs early in embryogenesis. [After Mary Francis Lyon (1925–), British geneticist.]

lyonium ion any cation produced by the protonation of a solvent molecule, e.g. H_3O^+ , CH_3OH_2^+ .

lyophile 1 (*in chemistry*) a lyophilic compound. **2** having lyophilic properties.

lyophilic or **lyophile** (of a substance or surface) solvent preferring; easily wetted or solvated by the solvent present; the term comprehends hydrophilic when the solvent is water. *Compare* lyophobic.

lyophilic sol any sol in which the disperse phase has an attraction for the continuous phase.

lyophilization or **lyophilisation** strictly, the process of rendering lyophile or lyophilic. The term is now usually specifically applied to freeze-drying in which, by use of a vacuum, water is removed from ice by sublimation. This use bears little relationship to the true meaning of lyophile, except in so far as it maintains proteins subjected to it in a lyophilic state. —**lyophilize** or **lyophilise** *vb.*

lyophilizer or **lyophiliser** an apparatus for effecting lyophilization; a freeze-drier.

lyophobic or **lyophobe** (of a substance or surface) solvent rejecting; resistant to being wetted or solvated by the solvent present; the term comprehends **hydrophobic** when the solvent is water. *Compare lyophilic.*

lyophobic sol any sol in which the disperse phase has no attraction for the continuous phase. Lyophobic sols cannot be formed by spontaneous dispersion in the medium.

lyotropic or **lyotrope** of or associated with the difference between the internal pressure of a solution compared with that of the solvent caused by the solute.

lyotropic mesophase any mesophase (i.e. **liquid crystal**) whose phase transitions are readily effected by changes in concentration.

lyotropic series or **Hofmeister series** a series of ions arranged in order of their **lyotropic** effects, especially their ability to cause precipitation of a lyophilic sol (to salt-out).

lypressin *see* [8-lysine]vasopressin.

Lys *symbol* for a residue of the α -amino acid L-lysine (alternative to K).

lys+ a variant form of **lyso+** (before a vowel).

lysate any solution or other preparation containing the products of **lysis** of cells. The term is applied especially to lysed bacterial or blood cells.

+lysate *comb. form* denoting a mixture resulting from decomposition, breakdown, or lysis (of or by something indicated); e.g. autolysate, cytolysate, hemolysate, hydrolysate.

Lys-bradykinin *abbr.* for lysylbradykinin (i.e. kallidin); *see* bradykinin.

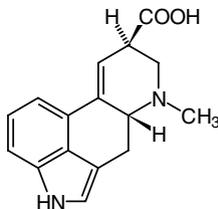

lyse to effect **lysis** (of a cell, etc.); to undergo lysis.

+lyse *comb. form* denoting decompose, breakdown, or lyse (of or by something indicated); e.g. autolyse, cytolysate, electrolyse, hemolyse, hydrolyse.

lysenin any of a family of pore-forming peptidic toxins with about 300 amino acid residues, permitting passage of small solutes, including water. They are produced by *Eisenia foetida* and are classified in the TC system under number 1.A.43.

lysergamide lysergic acid amide. All known **ergot alkaloids** are derivatives of D-lysergamide, the simplest being **ergonovine**.

lysergic acid 9,10-didehydro-6-methylargoline-8 β -carboxylic acid; an alkaloid obtained from **ergot**; it is a tetracyclic indole derivative. Lysergic acid diethylamide (*abbr.*: LSD) is a powerful hallucinogenic substance.

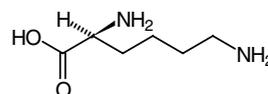

lysigeny (*in botany*) the disintegration of cells that occurs when new structures (e.g. aerenchyma or oil glands) are differentiating.

lysin any agent, such as an antibody, enzyme, toxin, etc., that is able to lyse cells.

+lysin *comb. form* denoting an (indicated) agent that effects, or can effect, lysis, specifically the lysis of cells (cytolysis).

lysinate 1 lysine anion; the anion, $\text{H}_2\text{N}-[\text{CH}_2]_4-\text{CH}(\text{NH}_2)-\text{COO}^-$, derived from **lysine**. 2 any salt containing lysine anion. 3 any ester of lysine.

lysine the trivial name for α,ϵ -diaminocaproic acid; 2,6-diaminohexanoic acid; $\text{H}_2\text{N}-[\text{CH}_2]_4-\text{CH}(\text{NH}_2)-\text{COOH}$; a chiral α -amino acid. L-Lysine (*symbol*: K or Lys), (S)-2,6-diaminohexanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: AAA or AAG. In mammals, it is an essential dietary amino acid, and is ketogenic. D-Lysine (*symbol*: D-Lys or D-Lys), (R)-2,6-diaminohexanoic acid, is a substrate for **lysine racemase** and D-lysine 5,6-aminomutase. The conversion of D-lysine to L-pipecolic acid, and of the latter to L-lysine, occurs in *Nicotiana glauca* and in *Neurospora crassa*.

L-lysine

D-lysine 5,6-aminomutase EC 5.4.3.4; *other name*: D- α -lysine mutase; an enzyme that catalyses the reaction:

cobalamin is a cofactor.

lysine(arginine) carboxypeptidase EC 3.4.17.3; *other names*: carboxypeptidase N; arginine carboxypeptidase; kinase I; anaphylotoxin inactivator; an enzyme that hydrolyses peptidyl-L-lysine (or L-arginine) to peptide and L-lysine (or L-arginine). It inactivates bradykinin complement components, C3a and C5a, by removal of the C-terminal Arg.

lysine (base) a lysine residue when the ϵ -amino group is unprotonated.

lysine hydroxylase *see* procollagen-lysine 5-dioxygenase.

lysine 6-monoxygenase *see* monoxygenase.

lysine-2-oxoglutarate reductase an alternative name for saccharopine dehydrogenase (NAD $^+$, L-lysine forming)

lysine racemase EC 5.1.1.5; an enzyme catalysing the reaction:

lysine tyrosylquinone *see* LTQ.

lysine vasopressin *see* [8-lysine]vasopressin.

[8-lysine]vasopressin *abbr.*: [Lys 8]vasopressin; *nonproprietary name*: lypressin; the molecular form of **vasopressin** in which the variable eighth position in its amino-acid sequence is occupied by a lysine residue. This is the form of the hormone present in pigs and a few other related mammals. It is sometimes incorrectly designated as lysine vasopressin.

lysinium 1 the usual term for lysinium(1+); the monocation of **lysine**.

In theory, the term denotes any ion, or mixture of ions, formed from lysine, and having a net charge of +1, although the species $\text{H}_3\text{N}^+ - [\text{CH}_2]_4 - \text{CH}(\text{NH}_3^+) - \text{COO}^-$ generally predominates in practice. 2 the systematic name for lysinium(2+); the dication of lysine.

lysino 1 N^2 -lysino the alkylamino group, $\text{H}_2\text{N}-[\text{CH}_2]_4-\text{CH}(\text{COOH})-\text{NH}-$, derived from lysine by loss of a hydrogen atom from its α -amino group. 2 N^6 -lysino the alkylamino group, $\text{HOOC}-\text{CH}(\text{NH}_2)-[\text{CH}_2]_4-\text{NH}-$, derived from lysine by loss of a hydrogen atom from its ϵ -amino group.

lysinuric protein intolerance a genetically determined metabolic defect of humans in which the ingestion of relatively large amounts of lysine (in protein) causes hyperlysinemia, hyperammonemia, and coma. The defect is probably in a cationic amino-acid transporter.

lysis 1 (*in chemistry*) the breaking down of a substance by the splitting of its molecules into two parts; the rupture of a covalent bond. 2 (*in biology*) the disintegration of cells or cell organelles by rupture of their outer membranes. 3 (*in medicine*) the gradual diminution in the severity of the symptoms of a disease; remission.

+lysis *comb. form* denoting breaking down, decomposition, disintegration, or dissolution. The first element of the word may indicate: (1) the agent, e.g. electrolysis, hydrogenolysis, biolysis; (2) the substance or object affected, e.g. glycolysis, lipolysis; or (3) some other characteristic, e.g. autolysis, catalysis, heterolysis, homolysis. —+lytic *adj.*

lyso+ or (*before a vowel*) **lys+** 1 *comb. form* indicating a dissolving or loosening; denoting lysis or the products of lysis. 2 *prefix* (to the name of a phospholipid) denoting removal of one of its two acyl groups; a locant may be used to designate the site of (hydro)lysis, e.g. 2-lyso designates deacylation at position 2. The term originated from the fact that such compounds are hemolytic, but it is now used to indicate a limited deacylation.

lysochrome any substance that will dissolve in lipids and colour them.

lysogen 1 any lysogenic bacterium. 2 any antigen that stimulates lysin production.

lysogenesis **1** an alternative term for **lysogeny**. **2** the production of a lysin or lysis.

lysogenic **1** pertaining to, or capable of producing or undergoing **lysis** (def. 1). **2** of, or relating to **lysogeny**. —**lysogenicity** *n.*

lysogenic bacterium any bacterium carrying a temperate bacteriophage as a **prophage** integrated into the bacterial genome. It has the potential to produce and release infective bacteriophages as a stable, heritable trait, which may become activated spontaneously or in response to certain stimuli. Moreover, it is immune to lytic infection by the same or closely related phages.

lysogenic conversion *see* **bacteriophage conversion**.

lysogenic virus any virus capable of becoming a **prophage**.

lysogenize or **lysogenise** to convert a nonlysogenic bacterial strain into a lysogenic strain by infection with a temperate bacteriophage, with resultant incorporation of the phage into the bacterial genome. —**lysogenization** or **lysogenisation** *n.*

lysogeny or **lysogenesis** the state created in a bacterial cell when the prophage of a temperate bacteriophage is incorporated into the bacterial genome as a stable, heritable character. Such a cell can be activated to produce and release mature phage, with accompanying cell lysis. *See also* **lysogenic bacterium**.

Lys(5-OH) *symbol* for a residue of the α -amino acid 5-hydroxy-L-lysine (less-preferred alternative to Hyl or 5Hyl).

Lysol the proprietary name for a disinfectant consisting of a mixture of *o*-, *m*-, and *p*-cresols solubilized with an excess of a potassium soap.

lysolecithin a former name for **lysophosphatidylcholine**.

lysolecithin acyltransferase *see* **1-acylglycerophosphocholine O-acyltransferase**.

lysophosphatidic acid any **phosphatidic acid** deacylated at positions 1 or 2.

lysophosphatidyl any **phosphatidyl** group deacylated at positions 1 or 2.

lysophosphatidylcholine or (formerly) **lysolecithin** any **phosphatidylcholine** (i.e. lecithin) deacylated at positions 1 or 2.

lysophospholipid any **phospholipid** deacylated at positions 1 or 2.

lysoplasmenic acid any derivative of *sn*-glycero-3-phosphate that has an *O*-(1-alkenyl) residue on carbon-1, the hydroxyl group in position 2 being unsubstituted.

lysoplasmenyl any **plasmenyl** group in which the hydroxyl group in position 2 is unsubstituted.

lysosomal carboxypeptidase B *see* **cysteine-type carboxypeptidase**.

lysosomal carboxypeptidase C *see* **lysine pro-X carboxypeptidase**.

lysosomal Pro-X carboxypeptidase EC 3.4.16.2; *other names*: proline carboxypeptidase; angiotensinase C; lysosomal carboxypeptidase C; an enzyme that catalyses the cleavage of a Pro-|-Xaa bond to release a C-terminal amino acid.

lysosomal storage disease any of a group of hereditary diseases, with widely varying manifestations, in which there is deficiency of a single lysosomal enzyme associated with abnormal deposits (of substrate) within membrane-bound vesicles. The group is subdivided into the following classes: type II **glycogen disease**, **mucopolysaccharidoses**, sphingolipidoses, **mucolipidoses**, and a few others.

lysosome any of a group of related cytoplasmic, membrane-bound organelles that are found in most animal cells and that contain a variety of hydrolases, most of which have their maximal activities in the pH range 5–6. The contained enzymes display latency if properly isolated. About 40 different lysosomal hydrolases are known and lysosomes have a great variety of morphologies and functions. —**lysosomal** *adj.*

lyso-staphin EC 3.5.1.–; an enzyme that hydrolyses polyglycine links in peptidoglycans. Zinc is a cofactor. Its physiological role is likely to be in the remodelling of the bacterial sacculus during growth. The C terminus has some similarity to **autolysin**.

lysozyme EC 3.2.1.17; *systematic name*: peptidoglycan *N*-acetylmuramoylhydrolase; *other name*: muramidase. An enzyme that hydrolyses β -1,4-linkages between *N*-acetylmuramic acid and 2-acetamido-2-deoxy-D-glucose residues in peptidoglycan heteropolymers (mucopolysaccharide or mucopeptide) of prokaryote cell walls. It occurs in tears, other exocrine secretions, and in very large amounts in the white of eggs of birds. The antibacterial action of lysozyme depends on the cleavage of the β (1 \rightarrow 4)glycosidic linkage between alternating units of *N*-acetylmuramic acid and *N*-acetylglucosamine that form long-chain mucopolysaccharides in the cell walls of bacteria such as *Micrococcus luteus*. There are a number of types of lysozyme, designated A–G. Lysozyme was the first enzyme whose 3-D structure was determined.

[Lys⁸]vasopressin *abbr. for* [8-lysine]vasopressin.

lysyl the acyl group, H₂N–[CH₂]₄–CH(NH₂)–CO–, derived from **lysine**.

lysylbradykinin or **Lys-bradykinin** an alternative name for kallidin; *see* **bradykinin**.

lyso endopeptidase EC 3.4.21.50; *other names*: *Achromobacter* proteinase I; lysyl bond specific proteinase. An extracellular bacterial serine proteinase that preferentially cleaves at Lys-|-Xaa, including Lys-|-Pro.

lysoyl oxidase EC 1.4.3.13; *recommended name*: protein-lysine 6-oxidase; *systematic name*: protein-L-lysine:oxygen 6-oxidoreductase (deaminating). A quinoprotein enzyme that catalyses a reaction between peptidyl-L-lysoyl-peptide, H₂O and dioxygen to form peptidyl-allysoyl-peptide, NH₃, and H₂O₂. It contains lysine tyrosylquinone as a cofactor. *See also* **allysine**.

+lyte *comb. form* indicating a substance that can be decomposed, broken down, or lysed.

lytic **1** of, pertaining to, or resulting from **lysis**. **2** of, or pertaining to a **lysin**.

+lytic *see* **+lysis**.

lyticase a jargon term for a combination of enzymes, with minimal amounts of nucleases, that displays two major activities: β -1,3-glucanase and a highly specific alkaline protease. It is prepared from *Oerskovia xanthineolytica* and is useful in removing cell walls from yeasts and fungi, causing extremely rapid cell lysis.

lytic cycle the sequence of events occurring when a sensitive bacterium is infected by a virulent bacteriophage. The phage diverts the metabolism of the cell to the exclusive production of progeny phage, resulting in the lysis of the host cell with liberation of phage.

α -lytic endopeptidase EC 3.4.21.12; a bacterial serine proteinase, a homologue of chymotrypsin, that hydrolyses proteins, especially at bonds adjacent to L-Ala and L-Val residues in bacterial cell walls, elastin, and other proteins.

lytic virus any virus including bacteriophages whose multiplication in a host cell leads to lysis of that cell.

Lyx *symbol* for a residue (or sometimes a molecule) of the aldopentose **lyxose**.

lyxo+ *prefix (in chemical nomenclature)* indicating a particular configuration of a set of three (usually) contiguous >CHOH groups, as in the acyclic forms of D- or L-lyxose. *See* **monosaccharide**.

lyxose *symbol*: Lyx; a *trivial name* for the aldopentose, *lyxo*-pentose; the C-2 epimer of **xylose**, rare in nature.

Mm

m symbol for 1 metre. **2** milli+ (SI prefix denoting 10^{-3} times).

m+ prefix (in peptide hormone nomenclature) denoting mouse, murine; derived, or as if derived, from a mouse.

m_r symbol for relative electrophoretic mobility.

m symbol for 1 mass; the various associated terms are distinguished by subscripts: *m_e*, symbol for electron rest mass; *m_n*, symbol for neutron rest mass; *m_p*, symbol for proton rest mass; *m_u*, symbol for atomic mass constant. **2** molality (alternative to *b*). **3** (bold italic) magnetic moment.

m- prefix (in chemical nomenclature) denoting *meta-*. Compare **o-**, **p-**.

M symbol for 1 mega+ (SI prefix denoting 10^6 times). **2** a residue of the α -amino acid L-methionine (alternative to Met). **3** a residue of an incompletely specified base in a nucleic-acid sequence that may be either adenine or cytosine. **4** mesomeric effect. **5** a metal (in chemical formulae). **6** molar (concentration), i.e. moles per litre (alternative to M or *M*; mol dm⁻³ is recommended). **6** 6-mercapto-purine ribonucleoside, 6-thioinosine.

M symbol for molar (concentration), i.e. moles per litre (alternative to M or *M*; mol dm⁻³ is the recommended form).

α_2 -M abbr. for α_2 -macroglobulin.

M symbol for 1 mass, especially molar mass; related terms are designated by subscripts: *M_m*, symbol for mass-average molar mass (see average molar mass); *M_n*, symbol for number-average molar mass (see average molar mass); *M₀*, symbol for mean relative residue mass; *M_r*, symbol for relative molecular mass; *M_w*, symbol for weight-average molar mass; *M_Z*, symbol for Z-average molar mass (see average molar mass). **2** molar (concentration), i.e. moles per litre (alternative to M or *M*; no longer recommended; use mol dm⁻³). **3** (or *M_v*) luminous exitance. **4** (or *M_e*) radiant exitance. **5** (bold italic) magnetization. **6** (bold italic) moment of a force.

M. abbr. for the modification enzyme associated with a type 2 restriction endonuclease. For example, M.*Hind*III is the enzyme associated with *Hind*III.

M9 a solution of inorganic salts used as the basis of minimal growth media for bacteria.

MAA abbr. for macroaggregated (human serum) albumin.

Mab abbr. for monoclonal antibody.

Mabthera a proprietary name for Rituximab.

MAC abbr. for 1 membrane attack complex. **MAC 1** is a cell-surface glycoprotein of monocytes, macrophages, and granulocytes that is implicated in adhesive interactions of these cells and in mediating the uptake of complement-coated particles. It probably recognizes the RGD peptide in complement component C3b. It is a heterodimer of α_M and β_2 chains (see integrin). **2** mammalian artificial chromosome.

machine address a binary number unique to a computer (more exactly its network hardware) that is used by a DNS (domain name server). It should be transparent to the average end-user. The number is usually represented as a colon-delimited hexadecimal, for example 00:01:02:1a:45:66.

machine language see programming language.

MACIF abbr. for membrane attack complex inhibition factor.

Mac-IP abbr. for Mac-inhibitory protein (i.e. CD59).

mackerel any marine fish of the subfamily Scombroidei. These fish are of importance as food fish, and their flesh is rich in oils with a relatively high content of *n*-3 fatty acids; typical composition (major fatty acids, expressed as percentage of total fatty acids): 14:0, 8%; 16:0, 16%; 18:0, 2%; 16:1 (*n*-7) 8%; 18:1 (*n*-9), 8%; 18:1 (*n*-7), 4%; 18:4 (*n*-3), 2%; 20:1 (*n*-9), 11%; 20:5 (*n*-3), 8%; 22:1 (*n*-11), 13%; 22:6 (*n*-3), 8%.

maconha see cannabis.

macro+ or (before a vowel) **macr+** comb. form 1 denoting large, long, or great in size or duration; large-scale. **2** denoting larger than normal, overdeveloped. Compare **micro+**.

macroaggregate any macromolecular aggregate large enough to be visible to the unassisted eye.

macrocycle any macrocyclic compound.

macrocyclic 1 (in chemistry) describing any compound containing a ring structure consisting of a large number (usually 15 or more) atoms. **2** (in biology) having a long life cycle.

macrocytic anemia anemia in which the circulating erythrocytes are larger than normal. It is often due to deficiency of vitamin B₁₂ (cobalamin) or folic acid.

macroglobulin any plasma globulin of >400 kDa. Macroglobulins include immunoglobulin M, α_2 -macroglobulin and many lipoproteins.

α_2 -macroglobulin abbr.: α_2 -M; a glycoprotein found in vertebrate plasma that strongly inhibits proteases of all classes. In humans, it constitutes about one third of the α_2 -globulins; its synthesis is enhanced in hypoalbuminemia, when it constitutes a major proportion of the increased α_2 -globulin band on electrophoresis strips. Human α_2 -M is a 726 kDa molecule comprising two pairs of disulfide-linked, identical 185 kDa subunits, which also contain heterodetic peptide rings containing reactive thiol ester linkages, each formed between the γ -carboxyl group of a glutamic residue and the thiol group of a cysteine residue in the same peptide chain. It can inhibit all four classes of proteinase by a mechanism involving a bait region. This contains specific sites, cleavage of which induces a conformational change that results in trapping of the protease: following cleavage in the bait region, a thiol-ester bond is hydrolysed, and mediates the covalent binding of the protein to the protease; subsequently, ϵ -amino groups of the protease react with the thiol-ester linkages in the inhibitor to form stable amide links. The entrapped protease is then able to act on substrates of low molar mass only.

macroglobulinemia or (esp. Brit.) **macroglobulinaemia** a condition in humans in which there is an increase in the concentration of macroglobulins, especially immunoglobulin M, in the blood. It is often associated with lymphocyte tumours.

macro histone 2A abbr.: macro H2Aa; the counterpart of histone H2A that replaces this in certain nucleosomes, with an implied role in nucleosome positioning.

macroion an ion of a macromolecule, especially one that does not pass through a dialysis membrane.

macrolide any antibiotic produced by *Streptomyces* spp. that contains a large lactone ring (see +olide) with few or no double bonds and no nitrogen atoms, linked to one or more sugar moieties. The macrolides include the carbomycins, the erythromycins, oleandomycin, oligomycins, and the spiramycins. They are active mainly against Gram-positive bacteria and they inhibit the early stages of protein synthesis.

macroligand any macromolecular ligand.

macrometabolite any metabolite present in a system in reasonably high concentration, especially as opposed to a trace metabolite, i.e. one present in extremely small concentrations.

macromolecule any molecule composed of a very large number of atoms, operationally defined as any molecule of mass greater than about 10 kDa (and ranging up to 10^2 MDa or more) that is incapable of passing through the pores of dialysis tubing as generally used. The term includes nucleic acids and most polysaccharides and proteins. Compare micromolecule. —**macromolecular** adj.

macronutrient any element that is required by living organisms in relatively large quantities for normal growth. Compare micronutrient.

macrophage any cell of the mononuclear phagocyte system that is characterized by its ability to phagocytose foreign particulate and colloidal material. Macrophages occur in connective tissue, liver (Kupffer cells), lung, spleen, lymph nodes, and other tissues. They contain prominent lysosomes, stain with vital dyes, and play an important part in nonspecific immune reactions.

macrophage-activating factor abbr.: MAF; see lymphokine.

macrophage-colony stimulating factor see colony stimulating factor.

macrophage inflammatory protein abbr.: MIP; a cytokine produced by B and T cells, monocytes, mast cells, and fibroblasts. MIP 1 α is a chemoattractant for monocytes, T cells, and eosinophils; it

also inhibits hematopoietic stem cell production. MIP 1 β is a chemoattractant for monocytes and T cells and is an adhesion molecule, binding to β_1 (VLA family) integrins.

macrophage migration enhancement factor *see* lymphokine.

macrophage migration inhibitory factor *abbr.*: MIF; *other name*: delayed early response protein 6; a lymphokine that is released by primed lymphocytes on incubation with the priming antigen. It inhibits the migration of macrophages out of macrophage-rich tissue such as spleen, and is probably a mediator of macrophage participation in inflammation.

macrophage scavenger receptor 1 a glycoprotein membrane receptor of macrophages and sinusoidal endothelial cells that binds and mediates uptake of oxidized low-density lipoproteins (LDL). It is implicated in deposition of cholesterol into arterial walls during atherogenesis. **2** a membrane receptor of hepatocytes and steroid hormone-producing cells that binds high-density lipoproteins (HDL), selectively removes cholesterol, and mediates its uptake.

macrophage system *see* mononuclear phagocyte system.

macropipette (*sometimes*) a pipette of similar construction to a standard plunger-type micropipette but of capacity in the range 0.25–5 mL.

macropore any pore (in a gel or porous solid) whose width is greater than about 50 nm. *Compare* mesopore, micropore. —**macroporous** *adj.*

macroreticular describing a three-dimensional polymer with a very open structure, the cross links being widely spaced.

macroscopic 1 of a size that is visible to the unaided eye. *Compare* microscopic (def. 1). **2** concerned with large units. *Compare* microscopic (def. 2). **3** relating to the behaviour of atoms or molecules in bulk. *Compare* microscopic (def. 3). —**macroscopically** *adv.*

macroscopic equilibrium constant any constant describing the overall equilibrium between two chemical entities that may be interconverted through two or more alternative intermediates. *Compare* microscopic equilibrium constant.

macrosolute *an operational term describing* any solute of a size larger than will pass through a membrane of a specified pore size or permeability limit.

macrotetrolide or **macrotetralide** any antibiotic that contains a 32-membered ring built up of four hydroxy-acid residues and containing four ether and four ester bonds; the group includes nonactin and related antibiotics. Some similar compounds have an open-chain structure, e.g. monensin and nigericin.

macula adherens *an alternative term for* desmosome.

MAD 1 a basic helix-loop-helix transcription factor capable of forming dimers with MYC and MAX. **2** *abbr. for* multi-wavelength anomalous dispersion.

MAD2 a protein in yeast that is an essential component of the spindle checkpoint during mitosis and determines the fidelity of chromosome distribution. Mutation leads to a large increase in the rate of chromosome missegregation during meiosis.

MadCAM *abbr. for* mucosal addressin cell adhesion molecule; MadCAM 1, M_r 58–66 kDa, is a member of the immunoglobulin superfamily of adhesion molecules. It is constitutively expressed on endothelial cells of post-capillary venules. It mediates lymphocyte homing to mucosal lymphoid organs and lamina propria venules, and binds L-selectin and integrin $\alpha_4\beta_7$.

mad cow disease *an informal name for* bovine spongiform encephalopathy.

madder the ground root of *Rubia tinctoria*, used as a plant dyestuff; the principal component is ruberythric acid.

MADS box a highly conserved amino acid sequence (\approx 56 amino acids) present in the floral 'homeotic' transcription factors APETALA1, APETALA3, PISTILLATA, and AGAMOUS of *Arabidopsis thaliana* and in many other proteins expressed in flowers of other plant species. *See* ABC model.

MAF *abbr. for* macrophage-activating factor; *see* lymphokine.

magainin any antibiotic peptide from *Xenopus* skin whose pore-forming activity (*see* PFP) results in the permeabilization of bacterial membranes. Magainins have a wide spectrum of action against bacteria, protozoa, and fungi. Magainin I has the sequence

GIGKFLHSAGKFGKAFVGEIMKS;

magainin II is (Lys¹⁰,Asn²²)-magainin I. An analogue with greater antibiotic potency is (Ala^{8,13,18})-magainin II amide. Magainins are classified in the TC system under number 1.C.16. *Compare* dermaseptin.

MAGE *see* visualization software.

magic spot I *see* magic spot (compound), ppGpp.

magic spot II *see* magic spot (compound), pppGpp.

magic spot (compound) *abbr.*: MS; either of the guanosine polyphosphates produced when stringent strains of *Escherichia coli* are starved of an amino acid required for protein synthesis. MS I is guanosine 5'-diphosphate 2'-(or 3')-diphosphate (*symbol*: ppGpp); MS II is guanosine 5'-triphosphate 2'-(or 3')-diphosphate (*symbol*: pppGpp).

magnesium *symbol*: Mg; a metallic element – an alkaline earth metal – of group 2 of the IUPAC periodic table; atomic number 12; relative atomic mass 24.305. It occurs naturally only in the combined state and is a mixture of stable nuclides of mass 24, 25, and 26. Magnesium is one of the most abundant elements of the Earth's crust (2.1%) and an essential component of all living material. It forms a divalent cation, Mg²⁺, which is a component of chlorophyll, occurs in bone, and is an essential cofactor for many enzymes, including the majority of enzymes utilizing ATP. It is a major biological cation, the fourth most abundant cation in the human, much of it being in the skeleton; the range in normal human plasma is 0.8–1.2 mmol L⁻¹. An excretion mechanism in the kidney is partly regulated by parathyroid hormone. *See also* magnesium-28.

magnesium-28 the artificial radioactive nuclide of magnesium, ²⁸Mg, of half-life 21.2 h. It emits a moderate-energy beta particle (i.e. electron) (0.46 MeV max.) and gamma radiation of various energies (1.35, 0.95, 0.40, and 0.031 MeV).

magnesium porphyrin *a general term for* chlorophyll.

magnet any body that can produce an appreciable magnetic field external to itself. Magnets may be either permanent or temporary. —**magnetic** *adj.*

magnetic beads microscopic synthetic polymer beads incorporating a magnetite core and chemically modified to enable the covalent attachment of proteins such as antibodies. Beads coated with streptavidin will bind proteins or DNA labelled with biotin. Such beads can be concentrated from suspension by exposing them to a magnetic field thereby providing an alternative to centrifugation.

magnetic circular dichroism spectroscopy measurement of circular dichroism of a coloured material which is induced by a magnetic field applied parallel to the direction of the measuring light beam. Even achiral materials exhibit MCD (the Faraday effect). Variable-temperature MCD is used for identifying and assigning electronic transitions originating from paramagnetic chromophores.

magnetic constant *symbol*: μ_0 ; *an alternative name for* permeability of vacuum.

magnetic dipole moment *symbol*: m or μ (*italic bold*); a vector quantity indicating the strength of a magnet: the product of a magnet's dipole moment and the ambient magnetic flux density gives the torque on the magnet. The SI unit is the A m² (ampere square metre = joule per tesla (J T⁻¹)).

magnetic field 1 a field of force existing in the neighbourhood of either a permanent magnet or a circuit carrying an electric current. Another magnet will experience a couple when placed in a magnetic field. **2** *an alternative name for* magnetic field strength.

magnetic field strength or **magnetic field** or (*formerly*) **magnetic intensity** *symbol*: H (*italic bold*); a vector quantity, the magnetizing force at any point in a medium. It is measured by a couple that would act on a small magnet of unit moment placed at that point with its axis at right angles to the direction of the magnetic field. It is the magnetic flux density, B , divided by the permeability, μ ; i.e. $H = B/\mu$. The SI derived unit $H = A\ m^{-1}$.

magnetic flux *symbol*: Φ ; a measure of the total strength of a magnetic field, defined as the scalar product of the magnetic flux density and the area. The SI derived unit is the weber.

magnetic flux density or **magnetic induction** *symbol*: B (*italic bold*); a pseudovector quantity, the magnetic flux passing through

unit area of a magnetic field orthogonal to the magnetic force. The SI derived unit is the **tesla**.

magnetic force the force exerted by a magnetic field on a magnetic pole or a moving electric charge. It may be either attractive or repulsive.

magnetic immunoassay *abbr.*: MAIA; a variant of **radioimmunoassay** in which the antibody is bound to a particulate, inert, magnetic support material – e.g. cellulose containing embedded grains of iron oxide, Fe_3O_4 – and separation of antigen–antibody complexes from free antigen is effected with the aid of a powerful magnet.

magnetic induction *an alternative term for magnetic flux density.*

magnetic intensity *a former name for magnetic field strength.*

magnetic lens *an alternative name for a magnetic electron lens.*

magnetic moment 1 *symbol*: μ ; a property of a charged particle arising from its spin; $\mu = eL/2mc$, where c is the velocity of light, L is the angular momentum of the particle, e is its charge, and m is its mass. The SI unit is joule per tesla. The **electron magnetic moment** (*symbol*: μ_e) is equal to $9.284\,7701 \times 10^{-24} \text{ J T}^{-1}$. The **proton magnetic moment** (*symbol*: μ_p) is equal to $1.410\,607\,61 \times 10^{-26} \text{ J T}^{-1}$. **2** *an alternative name for magnetic dipole moment.*

magnetic permeability *see permeability, permeability of vacuum.*

magnetic pole either of the two regions of a magnet into which the lines of force of the magnetic field converge or from which they diverge. They are designated north (or north-seeking) and south (or south-seeking) according to whether they are attracted to the Earth's north or south pole.

magnetic resonance *see electron-spin resonance spectroscopy, nuclear magnetic resonance, electron paramagnetic resonance spectroscopy.*

magnetic resonance imaging *abbr.*: MRI; an imaging technique that uses **nuclear magnetic resonance** (NMR) to investigate the state of tissues in the intact body; it is so-called to avoid the use of the term 'nuclear' in the treatment of patients. It has the advantage that it is non-invasive. A magnet large enough to surround a part of the body is used in conjunction with computer analysis to provide an image resulting from the NMR signals. The technique can distinguish extracellular water from that inside cells on the basis of protein spin relaxation rates; this distinction is used to reveal certain types of tissue damage.

magnetic shielding 1 protection from the effects of an external magnetic field. **2** (in **nuclear magnetic resonance spectroscopy**) the reduction of the applied magnetic field at an atomic nucleus (as compared with that applied to the whole sample) brought about by the electron cloud of the molecule.

magnetic stirrer any apparatus for stirring a liquid in which a follower – usually a small bar magnet coated in glass or plastic – may be caused to oscillate or rotate within the liquid under the influence of a more powerful magnet outside the container. Motion of the external magnet is controlled by a variable-speed electric motor. The term is sometimes applied specifically to the follower.

magnetic susceptibility *symbol*: X or (sometimes) X_m or K ; the ratio of the magnetization, M , produced in a substance to the magnetic field strength, H , applied to it, i.e.

$$X = M/H = \mu_r - 1,$$

where μ_r is the relative permeability of a vacuum. Paramagnetic materials have positive magnetic susceptibilities, diamagnetic materials have negative magnetic susceptibilities. (Note: the symbol μ_m is reserved for molar magnetic susceptibility.)

magnetism 1 the property of producing, or being affected by, magnetic flux. **2** the branch of physics concerned with magnets and magnetic phenomena.

magnetite *or magnetic iron oxide* *or black iron oxide* ferrosferic oxide; iron(II)–diiron(III) oxide; Fe_3O_4 ; a strongly magnetic black mineral form of iron oxide.

magnetization *or magnetisation 1* the act or process of magnetizing. **2** *symbol*: M (italic bold); the magnetic moment per unit volume of a magnetized body; i.e. the difference between the ratio of the magnetic flux to the permeability of vacuum and the magnetic field strength. The SI unit is the ampere per metre.

magnetization-transfer nuclear magnetic resonance spectroscopy a procedure in nuclear magnetic resonance spectroscopy in which one of the resonances is saturated by a strong radiofrequency

field, and the changes in the other resonances are observed. It is useful in measuring the rates of chemical exchange processes.

magnetize *or magnetise* to induce a magnetic flux density in (something); to cause (something) to exhibit **magnetism** (def. 1).

magnetogyric ratio *see gyromagnetic ratio.*

magneton a unit of magnetic moment. The **Bohr magneton** (*symbol*: μ_B) refers to an electron of mass m_e ; the **nuclear magneton** (*symbol*: μ_N) refers to a proton of mass m_p . They are related by the equation: $\mu_N = (m_e/m_p)\mu_B$.

magnetophoresis the movement of magnetizable particles through a fluid under the action of a magnetic field. It is useful for separating of dispersed cells to which ferromagnetic microspheres have been conjugated. —**magnetophoretic** *adj.*

magnetotactic referring to bacterial cells that align along a magnetic field. They contain crystals of magnetite.

magnification (*in microscopy*) the apparent linear enlargement of an object when viewed through a lens, system of lenses (as in a microscope, telescope, etc.), or other instrument. It is given by the ratio of the apparent diameter of the object, as seen using the lens, to its real diameter, as seen unaided.

Magnogel *a proprietary name for a bead-form support material useful in immunosorption and related procedures. It is similar to Ultragel but contains embedded particles of iron oxide, Fe_3O_4 , that enable the beads to be drawn to and held on the walls of the container by magnetism.*

MAIA *abbr. for magnetic immunoassay.*

Maillard reaction a nonenzymic reaction in which a reducing sugar combines at its anomeric carbon atom with an amino group of an amino acid, peptide, or protein to form first a Schiff base and then, by an **Amadori rearrangement**, the corresponding ketoamine. It is the first of a series of reactions that may occur during the processing and/or storage of food, resulting in a loss of nutritive value and the formation of a brown coloration; hence it is also known as the **browning reaction**. It may also be the reaction leading to the formation of hemoglobin A_{1c} in the erythrocyte. [After Louis Camille Maillard (1878–1936).]

main protease the protease that cleaves the polyprotein encoded in the RNA genome of coronaviruses. The human virus's main protease (305 amino acids) contains two six-stranded beta barrels and a cluster of five alpha helices. It cleaves on the carboxyl side of glutamine at about a dozen sites that contain Leu–Gln–Ala/Ser/Gly sequences.

major facilitator superfamily *abbr.* MFS, one of the two largest families of membrane transporters (the other being the ABC transporters). Transporters of this family are present ubiquitously in bacteria, archaea, and eukarya. They transport a wide range of metabolites and drugs, including sugars, amino acids, nucleosides, and a large variety of anions and cations. All members of the MFS possess 12–14 putative transmembrane α -helical regions, and exhibit a well-conserved motif present between transmembrane regions 2 and 3.

major groove the larger and deeper of the two spiral grooves on the surface of a double-helical b-DNA molecule. *Compare minor groove.*

major histocompatibility complex *abbr.*: MHC; a complex of genetic loci occurring in higher vertebrates that encodes a family of cellular antigens, known in mice as **histocompatibility-2 antigens** (*abbr.*: H-2 antigens; *see histocompatibility antigen*) and in humans as human leukocyte-associated antigens (*abbr.*: HLA antigens; *see HLA histocompatibility system*). The MHC antigens are cell-surface glycoproteins and may be divided into two classes, designated I and II. In transplantation reactions, cytotoxic T lymphocytes respond mainly against foreign MHC glycoproteins of class I together with antigen, while the response against class II and antigen is mainly by helper T lymphocytes.

Class I MHC antigens (*or transplantation antigens*) are on the surface of most nucleated somatic cells and enable the immune system to distinguish self from foreign cells. They are encoded by three separate loci (H-2K, H-2D, and H-2L in mice; HLA-A, HLA-B, and HLA-C in humans). The antigenic activity resides in a transmembrane polypeptide chain, the α subunit, of ≈ 45 kDa (roughly 345 amino acids), which has a short hydrophilic C-terminal segment inside the cell and a large glycosylated N-terminal segment. The latter

is folded into three separate domains (two of which contain an intrachain disulfide bond) and exposed to the cell exterior, where it is noncovalently linked with the β subunit (of 11.5 kDa and also called β_2 microglobulin), which is homologous with a single Ig-like domain (see **immunoglobulin fold**). In humans, these proteins are also referred to as **HLA class I**.

Class II MHC antigens are found on the surface of most B lymphocytes, some T lymphocytes, and some macrophages and macrophage-like cells. They are encoded by murine I-region (*abbr.*: Ir) genes and human HLA-D genes, and contain a ≈ 33 kDa α chain and a 28 kDa β chain; the C-terminal regions of both subunits have transmembrane and intracellular domains. Celiac disease is due to an allelic variant in one class-II gene.

majority-rule consensus tree (*in phylogenetics*) a tree in which groups of taxa that appear in 50% or more of the component trees are shown. *Compare consensus tree.*

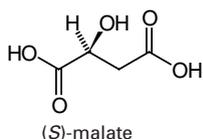

major tranquilizer a term, now deprecated, for any drug used to treat major psychosis, e.g. schizophrenia or mania; the term **neuroleptic** is now recommended.

MAK *abbr.* for methylated albumin-kieselguhr; a substance used as a medium for chromatography.

Makefile a file read by the UNIX utility make. It includes instructions for the computer and is used largely, but not exclusively, for compiling programs from source code. The advantage of make is that instructions on files that have not been altered since the last use of make are not repeated.

Mal 1 (when linked to one other group) *symbol* for the univalent maleyl group. **2** (when linked to two other groups) *symbol* for the bivalent maleoyl group.

malate 1 a *trivial name* for hydroxysuccinate; hydroxybutanedioate; $^-OOC-CH_2-CH(OH)-COO^-$; the dianion of malic acid, a chiral hydroxydicarboxylic acid. The (+)-enantiomer, (*S*)-malate (also designated L-malate), is an important intermediate in metabolism as a component of both the tricarboxylic-acid cycle and the glyoxylate cycle. **2** any mixture of free malic acid and its mono- and dianions. **3** any salt or ester of malic acid.

malate-aspartate cycle or **malate cycle** an intracellular metabolic cycle, also known as the malate-aspartate shuttle or malate shuttle, that can transfer reducing equivalents from the cytosol to the mitochondria in liver and other tissues. Oxaloacetate formed inside the mitochondria is there converted by a transaminase into aspartate, which passes through the mitochondrial membrane on a specific carrier; a similar transaminase in the cytosol converts this aspartate back into oxaloacetate, which then reacts with cytosolic NADH, in a reaction catalysed by cytosolic **malate dehydrogenase**, to form (*S*)-malate and NAD^+ . The malate thereupon passes back into the mitochondria, where it is dehydrogenated again to oxaloacetate, with concomitant reduction of mitochondrial NAD^+ to NADH and completion of the cycle.

malate dehydrogenase 1 *abbr.*: MDH or (*in clinical chemistry*) MD; EC 1.1.1.37; *recommended name*: malate dehydrogenase; *systematic name*: (*S*)-malate: NAD^+ oxidoreductase; *other name*: malic dehydrogenase. A widespread enzyme that interconverts malate and oxaloacetate according to the reaction:

In yeast, e.g., there are three isoenzymes: cytosolic, glyoxysomal, and of the mitochondrial matrix. **2** EC 1.1.1.82; *recommended name*: malate dehydrogenase ($NADP^+$); *systematic name*: (*S*)-malate: $NADP^+$ oxidoreductase. A chloroplast enzyme required for both C_3 and C_4 pathways (see **reductive pentose phosphate cycle**, **Hatch-Slack pathway**) to allow plants to circumvent the problem of photorespiration. It catalyses the reaction:

See also malate dehydrogenase (decarboxylating).

malate dehydrogenase (decarboxylating) any enzyme that brings about the oxidation of malate with simultaneous decarboxylation of the product to pyruvate. Such enzymes include: (1) Malate dehydrogenase (oxaloacetate decarboxylating), EC 1.1.1.38; *systematic name*: (*S*)-malate: NAD^+ oxidoreductase (oxaloacetate decarboxylating); *other names*: malic enzyme; pyruvic-malic carboxylase; malate oxidoreductase; it catalyses the reversible reaction:

(2) Malate dehydrogenase (decarboxylating), EC 1.1.1.39; *systematic name*: (*S*)-malate: NAD^+ oxidoreductase (decarboxylating); *other names*: malic enzyme; pyruvic-malic carboxylase; it catalyses a reaction between (*S*)-malate and NAD^+ to form pyruvate, CO_2 , and NADH. (3) Malate dehydrogenase (oxaloacetate decarboxylating) ($NADP^+$), EC 1.1.1.40; *systematic name*: (*S*)-malate: $NADP^+$ oxidoreductase (oxaloacetate decarboxylating); *other names*: malic enzyme; pyruvic-malic carboxylase; it catalyses a reaction between (*S*)-malate and $NADP^+$ to form pyruvate, CO_2 , and NADPH. It is important in generating NADPH in the cytosol of mammals. Thus types 1 and 2 utilize NAD^+ , while only types 1 and 3 decarboxylate added oxaloacetate, which leads to three activities being distinguished. (4) D-Malate dehydrogenase (decarboxylating), EC 1.1.1.83; *systematic name*: (*R*)-malate: NAD^+ oxidoreductase (decarboxylating); it catalyses a reaction between (*R*)-malate and NAD^+ to form pyruvate, CO_2 , and NADH.

malate synthase EC 4.1.3.2; *systematic name*: L-malate glyoxylate-lyase (CoA-acylating); *other names*: malate synthetase; malate condensing enzyme; glyoxylate transacylase. An enzyme that catalyses the formation of L-malate and CoA from acetyl-CoA, H_2O , and glyoxylate. This is the second step in the glyoxylate bypass, an alternative to the complete tricarboxylic-acid cycle (in bacteria and plants).

MALDI *abbr.* for matrix-assisted laser desorption/ionization; *see tandem mass spectrometry.*

maleate 1 the *trivial name* for *cis*-1,2-ethylenedicarboxylate; (*Z*)-butenedioate; the dianion of maleic acid, the diastereoisomer of fumarate. **2** any mixture of maleic acid and its mono- and dianions. **3** any salt or ester of maleic acid.

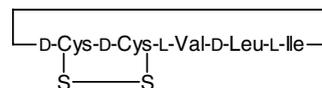

maleoyl *symbol*: Mal; the bivalent *cis*-acyl group, $-CO-CH=CH-CO-$, derived from maleic acid.

maleyl *symbol*: Mal; the univalent *cis*-acyl group, $HOOC-CH=CH-CO-$, derived from maleic acid.

maleylation the introduction of one or more **maleyl** groups into a substance by acylation, e.g. with maleic anhydride. Maleylation of a protein with maleic anhydride is used to acylate its free lysine (and other) amino groups in order to change their charge at neutral pH from positive to negative and to render the adjacent peptide bonds resistant to hydrolysis by trypsin; it can also lead to disaggregation of a multimeric protein. The reaction occurs at pH 8.5 (usually at 2°C) and the maleyl groups can be removed at pH 3.5 (usually at 60°C). Maleylation of thiol groups may also occur. *Compare citraconylation, succinylation.* —**maleylate** *vb.*

malformin A a cyclic pentapeptide from *Aspergillus niger* that causes curvature and malformations of various plants. The structure contains D-enantiomers of cysteine and leucine.

malic enzyme or **pyruvic-malic carboxylase** a *trivial name* applied to any of three enzymes, found in most organisms, that catalyse the oxidative decarboxylation of (*S*)-malate with concomitant production of pyruvate. *See malate dehydrogenase (decarboxylating).*

malignant (*in pathology*) **1** (of a tumour) invasive, spreading, resistant to therapy. **2** (of a disorder) becoming progressively more serious if not treated.

malignant hyperthermia a genetic disorder of humans and pigs that manifests as a fulminant episode of muscle rigidity, high fever, and acidosis, which is frequently fatal. In humans there is an autosomal dominant predisposition, with general anesthesia (frequently involving halothane inhalation) as the trigger. Most cases are associated with hyperexcitability of the ryanodine receptor. In pigs, the predisposition is autosomal recessive with stress as the trigger, and is associated with a point mutation in the same receptor.

malnutrition any imbalance, usually a deficiency, between the nutrients taken in by an organism and the amounts necessary to maintain that organism's normal development and health.

malonate 1 the trival name for propanedioate; methanedicarboxylate; $^{-}\text{OOC}-\text{CH}_2-\text{COO}^{-}$, the dianion of malonic acid. It is a potent competitive inhibitor of **succinate dehydrogenase**. **2** any mixture of free malonic acid and its mono- and dianions. **3** any salt or ester of malonic acid.

malonate semialdehyde the recommended trival name for malonate semialdehyde; formylethanoate; $\text{OHC}-\text{CH}_2-\text{COO}^{-}$. It is an intermediate in the oxidation of propionyl-CoA to acetyl-CoA in the terminal stages of the beta oxidation of fatty acids with an odd number of carbon atoms in plants.

malondialdehyde a compound produced by oxidation of unsaturated fatty acids. See **TBARS**.

malonyl 1 (*in biochemistry*) the univalent acyl group, $\text{HOOC}-\text{CH}_2-\text{CO}-$, derived from malonic acid by loss of one hydroxyl group. **2** (*in chemistry*) the bivalent acyl group, $-\text{CO}-\text{CH}_2-\text{CO}-$, derived from malonic acid by loss of both hydroxyl groups.

malonyl-CoA a key intermediate in fatty-acid biosynthesis, formed by reaction of carbon dioxide with acetyl-CoA, with hydrolysis of ATP to ADP and inorganic phosphate. This is catalysed by **acetyl-CoA carboxylase**; biotin is an essential cofactor. The plant enzyme also carboxylates propanoyl-CoA and butanoyl-CoA.

malonyl-CoA-acyl carrier protein transacylase EC 2.3.1.39; recommended name: [acyl-carrier-protein] S-malonyltransferase; systematic name: malonyl-CoA:[acyl-carrier-protein] S-malonyltransferase. An enzyme that catalyses a reaction between malonyl-CoA and ACP to form CoA and malonyl-ACP. It is a component of fatty-acid synthase in bacteria (see **fatty-acid synthase complex**).

maloyl the bivalent acyl group, $-\text{OC}-\text{CH}(\text{OH})-\text{CH}_2-\text{CO}-$, derived from malic acid by loss of the hydroxyl groups from both of its carboxyl groups.

Malpighian body or **Malpighian corpuscle** or **renal corpuscle** the part of a nephron comprising a cluster of blood capillaries (i.e. the renal glomerulus) together with the enclosing **Bowman's capsule**. [After Marcello Malpighi (1628–1694), Italian anatomist.]

malt 1 barley or other cereal grain that has been soaked in water, allowed to germinate, and then dried. In this process the starch of the cereal is largely degraded to maltose and other oligosaccharides. **2** to make into or become malt; to make or treat (something) with malt or an extract of malt.

maltase a trival name for α -glucosidase; see **glucosidase** (def. 2).

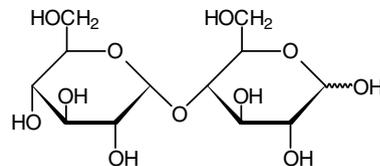

malto+ comb. form (*in chemical nomenclature*) designating an oligosaccharide or polysaccharide (e.g. maltose, maltotriose, maltoheptaose) consisting of D-glucopyranose residues in ($\alpha 1 \rightarrow 4$)-linkage (as in maltose).

maltol 3-hydroxy-2-methyl-4-pyrone; a flavour enhancer and modifier with a characteristic smell of candyfloss or burnt bread. Ferri(III) trimaltol is effective in the treatment of iron deficiency anemia.

maltoporin a bacterial outer membrane transmembrane protein, with possibly 16 helices, having two roles in *Escherichia coli*: it transports maltodextrins (including maltose) into the cell, and acts as a receptor for lambda and some other phages.

maltose or (*formerly*) **malt sugar** the trival name for the disaccha-

ride 4-O- α -D-glucopyranosyl-D-glucopyranose. It is an intermediate in the enzymic breakdown of glycogen and starch.

maltotriose the trisaccharide $\text{Glc}(\alpha 1-4)\text{Glc}(\alpha 1-4)\text{Glc}$; it is formed by the action of α -amylase on starch.

malt sugar a former name for maltose.

malyl either of the isomeric univalent acyl groups, $\text{HOOC}-\text{CH}(\text{OH})-\text{CH}_2-\text{CO}-$ or $\text{HOOC}-\text{CH}_2-\text{CH}(\text{OH})-\text{CO}-$, derived from malic acid by loss of a hydroxyl group from one or the other of the carboxyl groups.

MAML abbr. for microarray markup language; see **markup language**.

mamma (*pl. mammae*) a mammary gland. —**mammary** *adj.*

mammal any animal of the Mammalia, a large class of warm-blooded tetrapod vertebrates characterized by the possession of sweat glands in the skin and, generally, an insulating layer of hair. Female mammals characteristically suckle their young at modified sweat glands – mammary glands – that secrete milk. Like birds, mammals possess a four-chambered heart, but their thoracic diaphragm is a uniquely mammalian feature. —**mammalian** *adj.*

mammalian artificial chromosome abbr.: MAC; a still hypothetical mammalian counterpart of a **yeast artificial chromosome** (YAC).

mammalian target of rapamycin see **mTOR**.

mammary gland or **mamma** the milk-secreting organ of a mature female mammal. The mammary glands occur in one or more pairs on the ventral surface.

mammotropic or **mammotrophic** an alternative term for **lactotropic**.

mammotropic hormone or **mammotrophic hormone** an older name for **prolactin**.

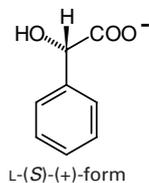

mammotropin or **mammotrophin** an older name for **prolactin**.

Man symbol for a residue (or a molecule) of the aldohexose mannose. In the condensed system of symbolism of sugar residues it signifies specifically a mannose residue with the common configuration and ring size, i.e. D-mannopyranose.

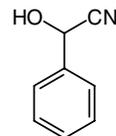

manaoic acid see **cyclic fatty acid**.

Mancini technique see **single radial immunodiffusion**.

mandelate α -hydroxybenzeneacetate; the anion, $\text{C}_6\text{H}_5-\text{CH}(\text{OH})-\text{COO}^{-}$, derived from mandelic acid, the α -carbon atom of which is chiral. **2** any salt or carboxylic ester of mandelic acid.

mandelonitrile α -hydroxybenzeneacetonitrile; benzaldehyde cyanohydrin; a compound that occurs free and as β -glucosides of (+)-, (–)-, and (\pm)-mandelonitrile.

manganese symbol: Mn; a ferromagnetic, metallic transition element of group 7 of the IUPAC **periodic table**; atomic number 25; rel-

ative atomic mass 54.938. There is one stable nuclide of mass number 55. Manganese is widely distributed and abundant in the Earth's crust and is an essential component of all living material. It forms manganese(II) (manganous) and less stable manganese(III) (manganic) compounds, including ionic compounds, and complexes; it can also exist in higher oxidation states. Mn^{2+} ions act as activators of various enzymes. A number of artificial radioactive isotopes are known.

manifold a vessel or tube with a number of inlets or outlets used to collect or distribute gases or liquids in an apparatus.

manna a sweet-tasting, white to yellow dried exudate of the manna ash tree (*Fraxinus ornus*) and other plants. *See also* **manninotriose**.

mannan the main **hemicellulose** of soft (coniferous) wood, made up of D-mannose, D-glucose, and D-galactose in the ratio of 3:1:1. Glucomannans occur in ferns and in certain higher plants and algae where they may function as the main structural component of the cell wall. Highly branched mannans can be extracted from the cell walls of some yeasts.

mannanase or **mannase** *see* **mannosidase** (def. 2).

Mannich reaction any chemical reaction in which an imminium ion of the type $CR_2=N^+R_2$ reacts with a nucleophilic carbon atom, such as that of an enolate anion derived from a ketone or that of an activated double bond as in a phenol, aryl ether, pyrrole, or indole. Mannich reactions are believed to occur widely in biosynthetic pathways of polycyclic compounds, especially alkaloids and porphyrins. [After Carl Mannich (1877–1947).]

manninotriose the trisaccharide Gal(α 1-6)Gal(α 1-6)Glc; a component of **stachyose**, it also occurs free in **manna** from ash trees.

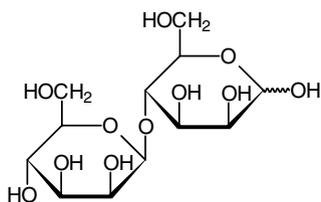

mannite a former name for **mannitol** (use deprecated).

D-mannitol the alditol derived from D-mannose by reduction of the -CHO group. It is widespread in higher plants, plant exudates, and algae, and is obtained from the manna ash (*Fraxinus ornus*) and seaweeds. Mannitol is metabolized by a number of bacteria including many strains of *Escherichia coli* and *Salmonella* spp. Clinically it is administered intravenously as an osmotic diuretic.

manno+ *comb. form* of mannose.

manno- *prefix (in chemical nomenclature)* indicating a particular configuration of a set of (usually) four contiguous >CHOH groups, as in the acyclic forms of D- or L-mannose. *See* **monosaccharide**.

mannobiose the disaccharide Man(β 1-4)Man; a constituent of D-glucosyl-D-mannans isolated from hardwoods, and of polysaccharides from iris, orchid, and lily families.

mannoheptulose *manno*-2-heptulose; the D enantiomer (formerly known as D-manno-ketoheptose) occurs in the avocado.

mannokinase EC 2.7.1.7; an enzyme that catalyses the phosphorylation by ATP of D-mannose to D-mannose 6-phosphate with release of ADP. It initiates the further metabolism of mannose, e.g. after uptake by bacteria. Hexokinase has a wide specificity for sugars and catalyses this reaction, e.g., in mammalian liver.

mannosamine *symbol*: ManN; a *trivial name* for 2-amino-2-deoxymannose.

mannose *symbol*: Man; a *trivial name* for the aldohexose *mannohexose*, the C-2 epimer of **glucose**. The D-(+)-form is widely distributed in mannans and hemicelluloses and is of major importance in the core oligosaccharide of N-linked oligosaccharides of glycoproteins, especially at branch points. A commonly occurring structure is Man(α 1-6)[Man(α 1-3)]Man(β 1-4)GlcNAc(β 1-4)GlcNAc-Asn.

mannose-binding protein (*abbr.*: MBP) or **mannose-binding lectin**

a **collectin** secreted by hepatocytes as an acute-phase response protein into human plasma. The clusters of **lectin** domains bind mannose residues on microbial and fungal surfaces in a Ca^{2+} -dependent manner. It activates (in the third pathway) the C3 component of **complement** after binding to C1q receptors, and its structure resembles that of C1q. It acts through the serine protease **MASP** associated with it. Macrophages have a membrane-bound MBP. Hereditary deficiency or dysfunction results in increased frequency of bacterial infections in infants and children, and is a frequent finding in lupus erythematosus and rheumatoid arthritis patients.

mannose 6-phosphate an intermediate in **mannose** metabolism, formed from mannose by **mannokinase** or from fructose 6-phosphate by **mannose-6-phosphate isomerase**. Apart from acting as a precursor in GDPmannose formation, it is a component of lysosomal enzymes, playing an important role in sorting the enzymes into lysosomes. *See also* **1-cell disease**, **mannose 6-phosphate receptor**.

mannose-1-phosphate guanylyltransferase EC 2.7.7.13; *other name*: GTP-mannose-1-phosphate guanylyltransferase; an enzyme that catalyses the reaction between GTP and α -D-mannose 1-phosphate to form GDPmannose with release of pyrophosphate.

mannose-1-phosphate guanylyltransferase (GDP) EC 2.7.7.22; *systematic name*: GDP:D-mannose-1-phosphate guanylyltransferase. An enzyme involved in M-antigen biosynthesis in salmonellae; it catalyses a reaction between GDP and D-mannose 1-phosphate to form orthophosphate and GDPmannose. This protein belongs to the **mannose-6-phosphate isomerase** family 2.

mannose-6-phosphate isomerase EC 5.3.1.8; *systematic name*: D-mannose-6-phosphate ketol-isomerase; *other names*: phosphomannose isomerase; phosphohexoisomerase; phosphohexomutase. An enzyme that catalyses the reaction:

zinc is a cofactor. The sequences belong to two families. Most enzymes (including human) belong to family 1. Family 2 is represented by an enzyme involved in alginate metabolism. *See also* **mannose-1-phosphate guanylyltransferase**.

mannose 6-phosphate receptor a protein on the surface of membranes in the Golgi apparatus and late endosomes that recognizes mannose 6-phosphate residues on lysosomal enzymes and is responsible for sorting them into late endosomes, which then become lysosomes. Lysosomal enzymes bearing phosphomannosyl residues bind specifically to mannose-6-phosphate receptors in the Golgi apparatus, and the resulting receptor-ligand complex is transported to an acidic prelysosomal compartment where the low pH mediates dissociation. There are two types of receptor protein. (1) The cation-dependent type, or M6P receptor, is a type I membrane glycoprotein homodimer involved in transport of phosphorylated lysosomal enzymes from the Golgi apparatus and the cell surface to lysosomes. It binds one molecule of M6P, does not bind insulin-like growth factor II (IGFII), and has an N-terminal region homologous to the repeats of the second type. (2) The cation-independent type, or M6P/IGFII receptor, is a type I glycoprotein membrane receptor that binds two molecules of M6P, and at a different site, IGFII. Its N-terminal region contains 15 homologous repeats (each of \approx 145 amino acids) homologous to that in the N terminus of the first type. *See also* **1-cell disease**.

mannosidase 1 α -mannosidase; EC 3.2.1.24; *systematic name*: α -D-mannoside mannohydrolase; an enzyme that catalyses hydrolytic removal of terminal, nonreducing residues in α -D-mannosides. **2** β -mannosidase EC 3.2.1.25; *systematic name*: β -D-mannoside mannohydrolase; *other names*: mannanase; mannase; an enzyme that catalyses hydrolytic removal of terminal, nonreducing residues in β -D-mannosides.

Both enzymes function in lysosomes at an acid pH, in the degradation of glycoproteins. Deficiency of either activity leads to a form of mannosidosis. *See also* **ER mannosidase**, **Golgi mannosidase**.

mannoside any **glycoside** in which the sugar moiety is a **mannose** residue.

α -mannosidosis a genetic disorder of humans characterized by abnormal storage and urinary excretion of mannose-rich oligosaccharides due to deficiency of lysosomal α -mannosidase activity. Type I

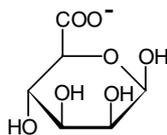

is a severe or infantile form. Type 2 is milder and appears in juveniles and adults.

β-mannosidosis a genetic disorder of humans, less frequent than α-mannosidosis, characterized by abnormal accumulation and urinary excretion of the disaccharide Manβ-1,4-*N*-acetylglucosamine, due to deficiency of lysosomal β-mannosidase.

mannosyl any of the glycosyl ligands formed by detaching the anomeric (α- or β-) hydroxyl group, on C-1, from a cyclic form (pyranose or furanose) of mannose.

α-1,3-mannosyl-glycoprotein β-1,2-*N*-acetylglucosaminyltransferase EC 2.4.1.101; *other name*: *N*-glycosyl-oligosaccharide-glycoprotein *N*-acetylglucosaminyltransferase I (*abbr.*: GlcNAc-TI or GNT-I); an enzyme involved in the synthesis of oligosaccharides, particularly those that are N-linked in glycoproteins. It catalyses the reaction between UDP-*N*-acetyl-D-glucosamine and α-D-mannosyl-1,3-(R)-β-D-mannosyl-R' to form *N*-acetyl-β-D-glucosaminyl-1,2-α-D-mannosyl-1,3-(R)-β-D-mannosyl-R' with release of UDP.

mannuronate 1 the anion of mannuronic acid, the compound formed by oxidation of the C-6 hydroxymethylene group of mannose to a carboxyl group. 2 any salt or ester of mannuronic acid. D-Mannuronic acid is a component of **alginate**.

β-D-pyranose form

manoalide a naturally occurring marine sesterterpenoid. It is an irreversible inhibitor of phospholipases A₂ and C, and a potent inhibitor of Ca²⁺ mobilization.

manometer an instrument for measuring pressure differences. The simplest type consists of a U-tube filled with a suitable liquid (often mercury), and compares a pressure delivered to one side with atmospheric pressure on the other, open, side of the tube. The difference in the level of liquid in the two arms of the tube gives a measure of the unknown pressure. In biochemistry the term is often used to mean a manometric **respirometer**.

manometer constant a predetermined factor, calculated for each individual constant-volume manometric **respirometer**, that when multiplied by the manometer reading immediately gives the volume of gas evolved in cubic millimetres at **standard** temperature and pressure. The factor is itself dependent upon temperature, liquid volume, density of the manometer fluid, and nature of the gas phase.

manometer fluid any fluid used to fill a **manometer**. In biochemistry this usually refers to the fluid used to fill the manometer of a respirometer. Such fluids are generally easily visible, wet the glass walls of the manometer, have a density that will give an easily calculated manometer constant, and have a low vapour pressure. Examples include **Brodie's fluid**, and **Krebs' manometer fluid**.

manometric 1 of, pertaining to, or measured with a **manometer**. 2 (*in biochemistry*) of, or pertaining to, a manometric respirometer. —**manometrically** *adv.*

manometry 1 the measurement of gas pressure by means of a manometer. 2 (*in biochemistry*) the use of manometric respirometers in studies of chemical and biochemical reactions.

Manp *symbol* for a mannopyranose residue.

mantissa the fractional part of any **logarithm**.

MAO *abbr.* for monoamine oxidase.

MAO inhibitor *abbr.* for monoamine oxidase inhibitor.

map 1 any representation of the surface features of an object, especially the spatial relationships of physical or chemical landmarks, as in **electron-density map**, **genetic map**, and **restriction map**. By extension the term is applied to certain two-dimensional patterns obtained in

analysis, e.g. **peptide map**. 2 to make a **map** (def. 1). 3 to occur, or be placed, at a specific position on a **map** (def. 1).

MAP *abbr.* for microtubule-associated protein.

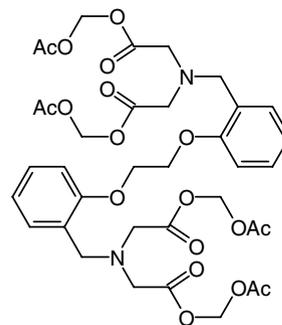

map distance (*in genetics*) the distance, in terms of percentages of crossing-over (i.e. 100 × no. of recombinants/total no. of progeny), between particular linked genes. *See also* **map unit**.

MAP kinase *abbr.* for mitogen-activated protein kinase; a family of protein kinases that perform a crucial step in relaying signals from the plasma membrane to the nucleus. They are turned on by a wide range of proliferation- or differentiation-inducing signals. For example, the MAP kinase FUS3 of *Saccharomyces cerevisiae* is required for the transition from mitosis into conjugation. The name does not indicate that this is a kinase for MAPs – rather that it is a protein kinase that is mitogen-activated. Nevertheless, some MAPs can be substrates for this enzyme. *See also* **ERK**.

MAP kinase kinase *abbr.*: MAPKK; EC 2.7.1.–; a dual-specificity mitogen-activated protein kinase kinase; *other names*: erk activator kinase; extracellular signal-regulated kinase; an enzyme that catalyses the concomitant phosphorylation of threonine (T) and tyrosine (Y) residues in a TEY sequence in **MAP kinases**. It requires activation by the serine/threonine kinase, MAP kinase kinase kinase (*see* **RAF**).

maple-syrup urine disease or **branched-chain ketonuria** an autosomal recessive disease of humans characterized by neurological signs and the onset of feeding problems in the first week of life, and associated with a maple-syrup odour of the urine. The concentrations of branched-chain amino acids and branched-chain keto acids are elevated in the blood of patients, due to deficiency of the enzyme responsible for the oxidative decarboxylation of branched-chain keto acids.

MAPTAM 1,2-bis-(2-amino-5-methylphenoxy)ethane-*N,N,N',N'*-tetraacetic acid tetraacetoxymethyl ester; a substance that readily penetrates cell membranes and undergoes intracellular hydrolysis with the formation intracellularly of the 5-methyl form of **BAPTA**. It is useful as an indicator of intracellular calcium concentrations.

map unit or **Morgan's unit** a unit of genetic length along a chromosome and defined in terms of recombination frequency, expressed as a percentage; a recombination frequency of 1 per cent (that is one recombinant individual in a hundred progeny) equals one map unit. 1 map unit = 1 centimorgan. *Compare* **morgan**.

maquette a protein designed *de novo*, to investigate properties such as electron transfer.

MAR 1 *abbr.* for matrix attachment region. 2 *abbr.* for matrix-associated region; a region of DNA that binds to the nuclear protein network and segregates chromosomal subdomains.

marasmus a wasting away of the body, especially of infants, caused by chronic deficiency of intake of energy-producing foodstuffs. *Compare* **kwashiorkor**.

marcks *abbr.* for myristoylated alanine-rich C kinase substrate; a filamentous (F) actin cross-linking protein and the most prominent substrate for protein kinase C. It also binds calmodulin, actin, and synapsin and is displaced from the membrane by phosphorylation by protein kinase C.

Marcus theory a set of equations that describe the rates of electron

transfer between molecules, also applicable to transfer between electron carriers within a protein. The rate depends on the energy barrier to electron transfer, which involves reorganization of the structures so that the potentials of donor and acceptor are equal. The theory leads to the counterintuitive conclusion that above a certain driving force (the inverted region) a greater driving force leads to a decreased rate of electron transfer. [After Rudolph A. Marcus, winner of the 1992 Nobel Prize in Chemistry for his contributions to the theory of electron transfer reactions in chemical systems.]

marenostrin an alternative name for pyrin. See **familial Mediterranean fever**.

margarine a processed fat used as a substitute for butter. Modern margarines are prepared from hydrogenated natural fats, the trend in recent years having been to preserve a high content of nutritionally desirable **polyunsaturated fatty acids**. Apart from the oil or fat content, margarine contains a water phase that is 16–20% of content and includes water, cream, whole milk, skim milk (powder), whey, and buttermilk in various ratios; flavouring, which may include diacetyl, fatty acids, and ketones; colouring agents, mainly based on carotenes; additional vitamins A and D; and **antioxidants** such as di-*tert*-butyl *p*-cresol. The process was invented in 1869 by H. Mège-Mouriès on the order of Napoleon III to produce a cheap stable butter substitute. Mège-Mouriès churned a beef tallow fraction, known as **oleomargarine**, with cream.

marijuana see **cannabis**.

Mariotte bottle or **Mariotte flask** a device for providing a flow of liquid maintained at a constant pressure head; it is used, e.g., in column chromatography. It consists of a sealed flask, closed to the atmosphere, with an outlet at or near the bottom and an air inlet tube open to the atmosphere. The height of the bottom of the inlet tube is adjustable. When the flask is filled with liquid to a level above the bottom of the inlet tube the pressure of the liquid flowing from the flask is determined by the height of the bottom of the inlet tube above the outlet point. [After Abbé Edmé Mariotte (1620–84), French physicist.]

Mariotte's law an alternative name (*esp. Fr.*) for Boyle's law (see **gas laws**).

marker 1 an appropriate reference substance or material included in a sample being subjected to a separation procedure such as chromatography, electrophoresis, or density-gradient centrifugation. 2 see **biochemical marker**. 3 see **genetic marker**. 4 an alternative term for **label** (def. 3).

marker enzyme any enzyme of known intracellular location that can be assayed as an aid in following the isolation and purification of subcellular fractions.

marker gene any gene of known function and known location on a chromosome. Compare **genetic marker**.

marker rescue a process whereby one or more genetic markers from a UV-irradiated virus are integrated into an unirradiated helper virus in infected bacteria; such genes are thereby 'rescued' by recombination.

Markham still a simple, all-glass, steam-jacketed apparatus for the rapid and efficient steam distillation of a succession of small samples of volatile substances. It was designed especially for the distillation of ammonia as part of the micro-Kjeldahl procedure for the determination of nitrogen, but has been found to be prone to carry-over from one sample to the next. [After Roy Markham (1916–79), British biochemist.]

Markovnikov's rule a generalization stating that when a molecule of water, or a hydrogen halide, or some other polar substance, is added heterolytically across an asymmetrically substituted carbon-carbon multiple bond, the hydrogen atom or other more electropositive part of the molecule becomes attached usually to that carbon atom carrying the larger number of hydrogen atoms while the hydroxyl, halo, or other more electronegative part of the molecule becomes attached to that carbon atom carrying the smaller number of hydrogen atoms. [After Vladimir Vasilyevich Markovnikov (1838–1904), Russian chemist, who formulated the rule on empirical grounds (1870).]

markup language a language used to structure and label documents in a logical fashion. The labels may provide format informa-

tion on how the data should be presented visually (e.g. by a Web browser) or semantic information concerning the kind of data being represented. Markup languages facilitate text-based data exchange and can be understood by humans and machines. Examples include HTML (hypertext markup language), XML (extensible markup language), UML (universal markup language), and MAML (microarray markup language).

Markush structure a chemical structure in which multiple 'functionally equivalent' chemical entities are allowed in one or more parts of the compound. Markush structures are used for example in patents to protect an invention of related compounds, without requiring the inventor to prepare and test every possible compound. [After Eugene A. Markush, the first inventor to include them successfully in a U.S. patent, in 1924.]

Maroteaux-Lamy syndrome an alternative name for **mucopolysaccharidosis VI**.

marsh gas another name for **methane**.

MAS a human transforming gene that encodes a neuronal-type angiotensin III receptor. The latter is a G-protein-associated membrane receptor that activates phospholipase C.

maser a device for producing intense beams of microwave radiation of defined frequency. Compare **laser**. [From microwave amplification by stimulated emission of radiation.]

Mash *abbr. for* mammalian Achaete-Scute homologue; either of two mammalian genes that encode basic helix-loop-helix transcription factors and are related to the *Drosophila Achaete-Scute* genes. Mash-1 is expressed in precursor cells for the central and autonomic nervous systems and olfactory epithelium. Mash-2 is expressed in oocytes, preimplantation embryos, and placenta. See **AS-C protein**.

mask (*in sequence analysis*) to remove repeated or low-complexity regions from a sequence in order to improve the sensitivity of database-search programs. See **sequence filter**.

masked residue any residue in a biopolymer that is not accessible to, and cannot react with, a reagent specific for that type of residue, either because of the position of the residue or because of the nature of its immediate environment.

maskin a protein of *Xenopus laevis* that is involved in regulating the translation of mRNA during embryonal development. It interacts with cytoplasmic polyadenylation-element binding protein bound to the polyadenylation element at the 3' untranslated region of mRNA.

MASP *abbr. for* MBP-associated serine protease; a serine protease (100 kDa) that is associated with **mannose-binding protein** (MBP). It shares ≈39% homology with C1r and C1s of **complement**. Binding of MBP to microbial polysaccharides enhances activation of MASP.

maspin a **serpin**-like tumour suppressor of epithelial cells.

mass 1 *symbol: m* or *M*; one of the seven SI base physical quantities; the SI base unit of mass is the **kilogram**. 2 a general term for the quantity of matter in a body, a characteristic that is both a measure of the resistance of the body to changes in its velocity, i.e. **inertial mass**, and a measure of the force experienced by the body in a gravitational field, i.e. **gravitational mass**. Mass is commonly confused with weight. According to the theory of relativity, inertial and gravitational masses are equal, mass increases with velocity, and mass and energy are interconvertible.

mass action, law of a law stating that, for a homogeneous system, the rate of reaction of a chemical reaction is proportional to the active masses of the reacting substances; i.e. the rate is proportional to the product of the activities of the reactants, each raised to a power equal to the number of reactant molecules of that type that participate in the reaction.

mass-average molar mass see **average molar mass**.

mass concentration see **concentration** (def. 1a).

mass density see **concentration** (def. 1a).

mass fraction *symbol: w*; the mass of a specified component of a system divided by the mass of the system; it is dimensionless.

mass fragmentography a common but less rigorous name for **selected-ion monitoring**.

mass number an older name for **nucleon number**.

mass spec. *abbr. (colloquial)* for mass spectrometer, mass-spectrometric, or mass spectrometry.

mass spectrograph a mass spectrometer in which the ions fall on a photographic plate.

mass spectrometer *abbr.*: MS or (*colloquial*) mass spec.; any instrument for mass spectrometry.

mass spectrometry *abbr.*: MS or (*colloquial*) mass spec.; an analytical method for determining the relative masses and relative abundances of components of a beam of ionized molecules or molecular fragments produced from a sample in a high vacuum. It is applicable to any sample that is gaseous or volatile at low pressure, or that can be so rendered by derivatization. In the commonest version, the ions, generated usually by electron bombardment of the sample, are formed into a beam and then accelerated to a uniform velocity by means of an arrangement of electrically charged slits. The beam is then dispersed into a spectrum of particles of different mass-to-charge ratios, *m/e*, by application of a suitably disposed magnetic field. The ions of any particular *m/e* value may be focused on a collecting electrode by appropriate adjustment of the accelerating potential or magnetic field and the resulting ion currents measured electrometrically. With a suitably designed mass spectrometer the method can be used to determine the relative abundances of isotopes of an element or the relative molecular masses of two or more compounds, or used to aid the identification of a complex compound by the mass spectrum of the fragments generated from it on electron bombardment. *See also* gas chromatography/mass spectrometry, selected-ion monitoring. —*mass-spectrometric* *adj.*

mass spectrum a tracing, photographic record, or diagram of the relative numbers of different ions (representing molecules or molecular fragments) obtained (from a specimen) by mass spectrometry, ranked in order of their mass-to-charge ratios.

mass-to-charge ratio (*in mass spectrometry*) the ratio of the mass, *m*, of an ion to the charge, *e*, on the ion. *See also* mass spectrometry.

mass transfer the spontaneous and irreversible process of transfer of mass across nonhomogeneous fields, e.g. between liquid phases, or from one side of a membrane to another.

mass unit *see* atomic mass unit, dalton.

mast cell a type of leukocyte, of the subclass granulocyte; it is characterized by having numerous cytoplasmic basophilic granules rich in histamine together with 5-hydroxytryptamine and heparin. Degranulation of mast cells, with release of the vasoactive amines, occurs by reaction, through a specialized region of the Fc piece, of antigen with homocytotropic antibody (reagin) bound to the cell. This leads to an immediate hypersensitivity reaction.

mast cell degranulating peptide *abbr.*: MCDP; a major neurotoxic 22-residue peptide of bee venom: IKCNCKRHVIKPHICR-KICGKN-NH₂. It stimulates degranulation of mast cells, and selectively blocks the neuronal Ca²⁺-dependent K⁺ channel.

mast cell growth factor *see* stem cell factor.

mastoparan a tetradecapeptide neurotoxin from wasp venom: Ile-Asn-Leu-Lys-Ala-Leu-Ala-Ala-Leu-Ala-Lys-Lys-Ile-Leu-NH₂. It functions like melittin and mast cell degranulating peptide, in generating ion channels in membranes. It is classified in the TC system under number 1.C.16.

MATα2 yeast mating-type protein α-2 repressor; a regulatory DNA-binding protein that acts as a master switch in yeast differentiation by controlling gene expression in a cell-type-specific fashion. In α haploids and α/α diploids (*see* mating type) it represses the transcription of α-cell-specific genes. In α/α diploids it also forms a complex with MATα1 protein that represses haploid-specific gene expression.

matchmaker proteins *see* molecular matchmakers.

maternal-effect gene any gene expressed in females whose mRNA transcript is found in the egg. Notable examples from *Drosophila* are *oskar* and *bicoid* (*see* bicoid protein), which determine egg polarity.

maternal imprinting the epigenetic silencing of an allele inherited from the mother. *See* imprinting.

Math 1 a basic helix-loop-helix transcription factor that determines epithelial cell commitment in the mouse intestine. It is a downstream target in the notch signalling pathway, and is also involved in cell fate determination in the nervous system.

mathematics 1 *functioning as sing.* the group of related sciences concerned with number, space, shape, and quantity, and their inter-

relationships. **2** *functioning as sing. or pl.* the use of mathematical processes or operations in calculations or the solution of problems.

mating type one of the two types of *Saccharomyces cerevisiae*, *a* and *a*, that are necessary for mating, a process in which two haploid cells fuse. The resulting diploid cell, *a/a*, cannot mate, but can produce spores, giving rise to haploid cells by meiosis. The mating type of the haploid cell is determined by a single locus, the mating-type (*MAT*) locus. In *a* cells, this encodes a regulatory protein *a1*, and in an *a* cell it encodes two such proteins, *a1* and *a2*. In the *a/a* cell, the regulatory proteins *a1* and *a2* combine to generate a completely new pattern of gene expression. *See also* MATα2.

matricin an alternative name for matrix metalloproteinase.

matrilysin EC 3.4.24.23; *other names*: matrin; uterine metalloendopeptidase; matrix metalloproteinase 7 (*abbr.*: MMP7); putative (or punctuated) metalloproteinase-1 (*abbr.*: PUMP-1); an enzyme that catalyses the cleavage of Ala¹⁴-Leu¹⁵ and Tyr¹⁶-Leu¹⁷ in the B chain of insulin. It has no action on collagen types I, II, IV, or V. It cleaves casein and fibronectin and shows preference for gelatin chain α-2(I) over α-1(I). It is secreted as the precursor, matrilysin, and is activated by autocatalytic cleavage at Glu⁷⁷-Tyr⁷⁸. Zinc and calcium are cofactors.

matrin or DNA-binding protein F/G a zinc-finger DNA-binding protein of the fibrogranular areas of the nucleus. Matrins comprise a family of eight major polypeptides of nuclear matrices of rat liver and tissue culture cells, highly conserved between humans and mouse. The name has sometimes been used as a synonym for matrilysin and matrin F/G is therefore used to avoid confusion.

matripsin or matrix-type serine protease 1 (*abbr.*: MT-SP1) EC 3.4.21; a type 2 transmembrane serine protease of gastrointestinal tract, spleen, and prostate. The mouse orthologue shares 81% sequence identity with the human enzyme (855 amino acids).

matriseptin an alternative name for membrane type-serine protease 1. *See* MT-SP1.

matrix (*pl.* matrices or matrixes) **1** a medium or place wherein something is formed, develops, or is embedded or enclosed. **2** the medium that forms, or supports, the stationary phase in certain separative procedures, as in chromatography or zone electrophoresis; the material that forms, or is used to form, the substratum of an immobilized reagent in affinity chromatography. **3** (*in animal histology*) *see* extracellular matrix. **4** (*in plant histology*) the meshwork of soluble substances, largely polysaccharide in nature, occurring in cell walls and in which insoluble microfibrils of cellulose are embedded. **5** *see* mitochondrial matrix. **6** cytoplasmic matrix; *see* groundplasm. **7** the substratum, living or nonliving, in or on which a fungus or lichen grows. **8** (*in mathematics*) any rectangular array of numbers or symbols manipulable algebraically as a single entity and used according to specific rules to facilitate solving of certain kinds of problems, e.g. a set of simultaneous linear equations.

matrix attachment region *abbr.*: MAR; an AT-rich, ≈200-bp sequence of DNA that binds to the nuclear scaffold (the site of RNA synthesis) in the interphase nucleus. MARs anchor genes near the nuclear membrane; they are believed to help regulate transcription by controlling the chromatin state of DNA, mediating chromatin unfolding prior to expression.

matrix Gla protein a protein that mediates association of the organic matrix of bone and cartilage. It contains γ-carboxyglutamate (Gla) residues, formation of which is vitamin-K-dependent.

matrix metalloproteinase *abbr.*: MMP; any proteolytic enzyme associated with the extracellular matrix. The group includes: MMP1, interstitial collagenase; MMP2, gelatinase A; MMP3, stromelysin-1; MMP8, neutrophil collagenase; MMP10, stromelysin-2; MMP12, metalloelastase. They have been implicated in facilitating cell migration, and in the ability of malignant cells to invade tissues and metastasize. They convert tumour necrosis factor (TNF) precursor into active TNF and may be implicated in other diseases such as rheumatoid arthritis or osteoarthritis. For these reasons, there is current interest in matrix metalloproteinase inhibitors (*abbr.*: MMPis) as potential drugs. *See also* TIMP.

matrix metalloproteinase inhibitor *see* MMPi.

matrix processing peptidase *abbr.*: MPP; an alternative term for mitochondrial processing peptidase.

matrix protein 1 the major protein component of the outer mem-

brane of *Escherichia coli*. It is a transmembrane protein that forms hydrophilic pores permitting the passage of microsolutives; in association with **lipopolysaccharide** (def. 4) it forms a receptor for phages. It is a member of the **porin** family, and is a product of the gene *DMPC*. **2** any of a class of proteins that coat the inside of the lipid bilayer in the envelope of some groups of enveloped viruses.

matrix space or **(mitochondrial) lumen** the innermost compartment of a mitochondrion, containing the **mitochondrial matrix**.

matrix vesicle any of the minute, membrane-bound, extracellular particles (≈ 100 nm in diameter) occurring in the interstitial matrix of calcifying cartilage. The vesicles contain a number of enzymes involved with local calcification mechanisms.

maturation 1 the process of coming to full development, ripening, or becoming mature. **2** or **maturation division** the processes of formation of gametes (sperm or ova) from primary gametocytes involving meiosis of the nucleus with reduction of chromosome number from diploid to haploid. **3** (*in virology*) the overall process leading to the incorporation of a viral genome into a capsid and the development of a complete virion.

maturation-promoting factor an alternative name for **M-phase-promoting factor**.

maturation protein or **A protein** one of the three proteins encoded by certain single-stranded RNA bacteriophages, one molecule of which is necessary for proper encapsulation of the RNA and for binding of the phage to a pilus on the host cell.

mature mRNA the functional form of **messenger RNA** (mRNA) that results from capping, splicing, and polyadenylation of the primary transcript.

maturity-onset diabetes a former name for type 2 **diabetes mellitus**.

maturity-onset diabetes of the young *abbr.*: MODY; an autosomal dominant form of type 2 (non-insulin-dependent) diabetes mellitus that has early onset. Mutations of six genes have been implicated: MODY 1, HNF-4a (locus 12q24.31); MODY 2, glucokinase (locus 7p13); MODY 3, HNF-1a (locus 20q13.12); MODY 4, IPF-1 (locus 13q12.2); MODY 5, TCF2 (locus 17cen-q21.3); MODY 6, NEUROD1 (locus 2q32). MODY 3 and MODY 2, the most prevalent forms, account for more than 80% of Caucasian patients.

max *abbr.* for maximal or maximum.

MAX a gene family coding for DNA-binding proteins that function in cell growth control. The product, Max, forms heterodimers with Myc (*see* **MYC**) that bind specifically to CACGTG; it also forms homodimers of similar specificity. Max contains **helix-turn-helix** and heptad repeats.

Maxam-Gilbert method (for DNA sequencing) *see* **chemical cleavage method**.

maxicell or **maxi cell** a bacterial cell that has been heavily irradiated with UV light and in which the chromosomal DNA is extensively degraded. Any plasmid(s) present usually escape damage and the genes they encode can be expressed.

maxicircle DNA any large, closed circular DNA molecule, as in the kinetoplast of *Leishmania tarantolae*.

maxima a plural of **maximum** (def. 1).

maximal *abbr.*: max; of, pertaining to, or reaching a maximum; being the greatest possible in size, duration, etc.; **maximum** (def. 2). —**maximally** *adv.*

maximal agonist effect or **intrinsic activity** *symbol*: α ; the maximal effect that an agonist, whether conventional or inverse, can elicit in a given tissue under particular experimental conditions, expressed as a fraction of that produced by a full agonist acting through the same receptors under the same conditions.

maximal rate or **maximum rate** another name for **limiting rate**. *Symbol* V (recommended) or V_{\max} . *See* **Michaelis kinetics**.

maximal velocity or **maximum velocity** an older name for **limiting rate**.

maximum *abbr.*: max; **1** (*pl.* **maxima** or **maximums**) the highest or greatest possible amount, degree, etc.; the highest value of a variable quantity. *Compare* **minimum**. **2** of, being, or exhibiting a maximum or maxima; **maximal**.

maximum likelihood a statistical method for parameter estimation using a prespecified model and a set of empirical data. The parameter values are chosen to maximize the probability of observing

the data, given the hypothesis. In phylogeny, the method is used to find the tree topology with maximum likelihood, given the data and the model of sequence evolution, and to estimate branch lengths and other evolutionary parameters.

maximum parsimony the principle that a simpler solution is preferred to a more complex one. For example, in phylogenetics, a tree that requires the fewest evolutionary events to explain the data is preferable to a tree that requires more events.

maximum-scoring segment pair *abbr.*: MSP; the highest scoring of high-scoring segment pairs (HSPs) that result from the alignment-extension step in BLAST. *See* **alignment algorithm**.

Maxwell relation a relation between the dielectric constant, ϵ , and the refractive index, n , of a nonabsorbing, nonmagnetic material such that $\epsilon = n^2$. [After James Clerk Maxwell (1831–79), British physicist.]

Mb 1 *abbr.* for myoglobin; hence MbO₂, oxy-myoglobin; MbCO, carbonmonoxymyoglobin; etc. **2** *symbol* for megabase, i.e. = 10⁶ bases. **3** (*in computing*) *abbr.* for megabyte (i.e. 2²⁰ bytes; alternative to MB).

MBOAT *abbr.* for membrane-bound *O*-acyltransferase.

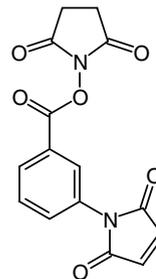

MboI a type 2 **restriction endonuclease**; recognition sequence: \uparrow GATC. *Sau3AI* is an **isoschizomer**.

MboII a type 2 **restriction endonuclease**; recognition sequence: GAA-GANNNNNNNN \uparrow .

MBP *abbr.* for mannose-binding protein.

MBP-associated serine protease *see* **MASP**.

MBS *abbr.* for meta-maleimidobenzoyl-*N*-hydroxysuccinimide ester; a heterobifunctional reagent useful, *inter alia*, for coupling an enzyme to an antibody, without appreciable loss of either activity.

MBSA *abbr.* for methylated bovine serum albumin.

mc (*formerly*) *abbr.* for millicurie (mCi now used).

Mc₃ *symbol* for mucotriose (McOse₃ preferred if space permits).

Mc₄ *symbol* for mucotetraose (McOse₄ preferred if space permits).

MCAD *abbr.* for medium chain acyl-CoA dehydrogenase; *see* **beta-oxidation system**.

McArdle's disease an alternative name for type V **glycogen disease**.

MCC the symbol for a gene (standing for 'mutated in colorectal cancer') that is closely linked to the *APC* gene at 5q21 in humans. It encodes a protein (829 amino acids) that may be a tumour suppressor. Somatic mutations of *MCC* occur in 5–10% of colorectal cancers.

MCD *abbr.* for **1** magnetic circular dichroism. **2** mean corpuscular (erythrocyte) diameter.

MCDP *abbr.* for mast cell degranulating peptide.

M cell or **microfold cell** a type of epithelial cell of intestinal mucosa that overlies patches of lymphoid tissue (Peyer's patches). M cells have an invaginated base in which lymphocytes and macrophages can aggregate. The cells present bacterial and viral protein antigens to the underlying lymphocytes, inducing proliferation of the latter and the secretory immune response.

McFarlane's method a method for the radioiodination of proteins with high efficiency in which the protein to be labelled is reacted with iodine monochloride that has been previously equilibrated with radioiodide. The extent of substitution can be precisely controlled by use of an appropriate quantity of iodine monochloride. [After Arthur Sproul McFarlane (1905–78), British biophysicist.]

MCH *abbr.* for melanin concentrating hormone.

mCi *symbol* for millicurie.

McIlwain chopper or **McIlwain–Buddle chopper** a hand- or motor-driven machine for rapidly cutting a piece of animal tissue into slices of uniform, preselected thickness (≥ 0.07 mm) and then, if desired, into prisms by making a second series of cuts. Such prisms can yield easily dispensed suspensions that retain those metabolic characteristics that tend to be lost on homogenization of tissue. [After Henry McIlwain (1912–92), British biochemist, and H. L. Buddle.]

McIntosh and Fildes jar *see anaerobic jar*.

McLeod gauge a mercury-in-glass vacuum pressure gauge that is capable of measuring down to 10^{-5} mmHg (1.33×10^{-3} Pa). A known large volume of gas is compressed into a small volume, in which the now much larger pressure is measured.

MCM protein any of six related ATPase proteins in budding yeast that are essential for initiation of replication. They assemble into a large ring complex around the DNA at the origin of replication complex (**ORC**), being stabilized by Cdc45. They appear in the nucleus during G₁ phase of the cell cycle, and are exported into the cytoplasm from S to G₂ phases. They are considered to function as a **licensing factor**, permitting one round of replication to occur per cell cycle. Mutants of the MCM homologue **PROLIFERA** in *Ara-bidopsis* are lethal.

McOse₃ *symbol for mucotriose* (preferred alternative to Mc₃).

McOse₄ *symbol for mucotetraose* (preferred alternative to Mc₄).

MCP *abbr. for methyl-accepting chemotaxis protein*.

MCS *abbr. for multiple cloning site*.

Md *symbol for mendelevium*.

MD (*in clinical chemistry*) *abbr. for malate dehydrogenase* (def. 1).

MDa *abbr. for megadalton*.

MDCK cell *abbr. for Madin–Darby canine kidney cell; a cell of a heteroploid cell line*.

MDH *abbr. for malate dehydrogenase* (def. 1).

Mdm2 or **MDM2** *abbr. for murine double minute chromosome protein 2; a protein, present mainly in mammalian cell nuclei, that is an E3 ubiquitin-protein ligase. It binds to p53 and targets it to ubiquitin-mediated degradation in proteasomes*.

MDMA *abbr. for 3,4-methylenedioxymethamphetamine*.

MDP *abbr. for muramyl-dipeptide*.

MDR *abbr. for multiple drug resistance or multidrug resistance; the acquired simultaneous resistance of tumour cells or pathogenic organisms to a wide spectrum of drugs arising from the administration, typically over long periods, of one or a limited number of drugs. Such resistance may extend to drugs with little structural or even functional similarity to the original drug(s), and results in reduced efficacy of all the drugs concerned. In long-term chemotherapy of cancer patients it is due to the induced expression of plasma membrane glycoproteins known as P-glycoproteins, or MDR proteins. In bacteria it is due to induction of multidrug transporters. See BmrR*.

MDR protein any transmembrane glycoprotein that is involved in (multiple) drug resistance (*see MDR*). MDR proteins belong to the ATP-binding cassette (ABC) class of the multidrug transporter superfamily, and are ATP-dependent. MDR1 (or P-glycoprotein 1) occurs in polarized epithelia of intestine, kidney, liver, and blood–brain barrier. MDR2 (or P-glycoprotein 2) is the phosphatidylcholine translocator of the bile canaliculi. MDR3 (or P-glycoprotein 3) is an efflux pump that is not capable of conferring drug resistance by itself. However, its absence leads to severe liver disease. MDR-associated protein participates in the active transport of drugs into subcellular organelles. MDR protein (or P-glycoprotein) of *Leishmania tarentolae* is a protein responsible for acquired methotrexate resistance, and is encoded by a gene located in the ‘H-circle’, a 68 kb duplex DNA circle containing a 30 kb inverted repeat.

Mdv1 a dynamin-like protein of yeast that contains WD repeats and is required, with Fis1 and Dnm1, in forming the contractile ring around the outer mitochondrial membrane that brings about fission of the organelle.

Me *symbol for the methyl group, CH₃–*.

Mead acid *a name sometimes given to (all-Z)-eicosa-5,8,11-trienoic acid. It can be synthesized de novo by mammals via palmitate and oleate, and is thought to substitute partially for the long-chain*

polyunsaturated fatty acids lacking in essential fatty acid deficiency. [After J. F. Mead, who first identified it as an acid found in elevated concentrations in mammals during essential fatty acid deficiency.]

mean or **arithmetic mean** or **average** the quotient of the arithmetic sum of any set of two or more numbers, measurements, values, etc. and the number of components of the set. *See also geometric mean. Compare median* (def. 1).

mean deviation the arithmetic average of the absolute values of the differences between the individual values of a set of numbers, values, etc. from their mean.

mean free path the average distance travelled by a molecular entity between collisions. In a gas, the mean free path between molecular entities is inversely proportional to the pressure of the gas.

mean ionic activity coefficient *symbol: γ_{\pm}* ; the average rational activity coefficient of the ions of an electrolyte that dissociates in solution into cations of charge z^+ and anions of charge z^- , given, according to the limiting law of the Debye–Hückel theory, by:

$$-\log \gamma_{\pm} = z^+ z^- A I^{0.5},$$

where A is a constant whose magnitude depends on temperature, dielectric constant, etc., having a value near 0.5, and I is the ionic strength of the solution.

mean life or **average life** *abbr.: τ* ; the mean of the lengths of time required for the disintegration of all atoms of a given radionuclide. It is related to the **half-life**, $t_{1/2}$, and to the **disintegration constant**, λ , of the radionuclide by the expressions:

$$\tau = t_{1/2} / \ln 2 = 1.443 t_{1/2},$$

and

$$\tau = 1/\lambda.$$

mean relative residue mass or (*formerly*) **mean residue weight** *symbol: M_0* ; the quotient of the relative molecular mass of a polymer and the number of residues it contains.

mean residue rotation the average molar optical rotation for a residue in a polymer. It is obtained by substituting the mean relative residue mass, M_0 , for the relative molecular mass, M_r , of the polymer in the equation defining **molar optical rotation**.

mean residue weight *a former name for mean relative residue mass*.

Mec *abbr. for the 4-methylcoumarin-7-yl group*.

mechanical concerned with, executed or operated by, or as by, a machine; relating to mechanics. —**mechanically** *adv*.

mechanically gated channel *see ion channel*.

mechanics **1** the science concerned with the equilibrium or motion of bodies in a given frame of reference. **2** the science of machines and/or machinery.

mechanism **1** the chain of events in a particular process; the action or process by which an effect is produced or an action performed. **2** (*in chemistry*) the detailed description of the pathway leading from reactants to products of a reaction, including where possible a characterization of the composition, structure, and other properties of any reaction intermediates and transition states. **3** any system or structure of moving parts that performs some function; a machine.

mechanistic of, pertaining to, or explained by mechanics; of, pertaining to, or resembling a mechanism. *Compare stochastic*.

mechanochemical coupling the coupling of a chemical process with a mechanical process in the same structure. *See also motor protein*.

mechano-transduction the activation of an intracellular effector pathway by a mechanical force, as in stretch receptors in the walls of the heart and blood vessels.

meconium antigen *see carcinoembryonic antigen*.

MECP2 *abbr. for methylCpG-binding protein 2*.

media **1** a plural of **medium**. **2** (*in morphology*) or **tunica media** the middle layer of the wall of a blood or lymph vessel.

medial **1** of, situated in, or towards the middle. **2** of, or pertaining to, a **media** (def. 2).

median **1** (*in statistics*) the centre value of any series of numbers, measurements, values, etc. when these are arranged in order from the lowest value to the highest value (with an even-numbered series, the mean of the two central values is taken); i.e. half the members of the series have values greater than that of the median and half have

median effective dose

values smaller than that of the median. *Compare mean.* **2** of, pertaining to, situated in, or pointing towards the middle. **3** (*in biology*) of or pertaining to the plane that divides an organism, organ, etc. into two symmetrical parts.

median effective dose *abbr.*: ED₅₀ or ED50; the dose of a drug, agonist, or other agent that is effective in 50% of the test objects.

median infectious dose *abbr.*: ID₅₀ or ID50; the dose of bacteria, viruses, or other infective agents that produces infection in 50% of the test objects.

median lethal dose *abbr.*: LD₅₀ or LD50; the dose of bacteria, viruses, toxic substances, or other agents that causes death of 50% of the test objects.

mediated diffusion *or, sometimes, facilitated diffusion* a specific membrane transport process on a transporter (carrier) that does not require coupling with energy and, in the case of nonelectrolytes, that leads to equal concentrations of the transported substance on both sides of the membrane.

mediated transport the transport of a substance across a (biological) membrane that requires the participation of one or more transporting agents (or **carriers** (def. 3)). *See also facilitated diffusion.*

mediator or **MED** a multiprotein complex (20–30 polypeptides, ≈2 MDa) that acts as a transcriptional coactivator of yeast. It bridges general initiation factors that bind to promoters of protein genes, and the C-terminal domain of the largest subunit of RNA polymerase II. The complex is distinct from that composed of general transcriptional activators, or of upstream stimulatory activity (USA) factors. Several mammalian complexes that have mediator-like transcriptional activity have been characterized. The human equivalents are **TRAP** and **SMCC**.

medical of, or pertaining to, the science or practice of medicine.

medical informatics *see informatics.*

medical subject headings *abbr.*: MeSH; the National Library of Medicine's controlled vocabulary of medical and scientific terms used to index articles in the bibliographic database MEDLINE. MeSH terms provide a consistent method of information retrieval when different terminology has been applied to the same concepts.

medicinal pertaining to or possessing therapeutic properties.

medicine **1** the science or practice of preventing, diagnosing, alleviating, and curing disease. **2** a common term for a pharmaceutical substance or mixture.

medin a 50-residue polypeptide, derived from the protein lactadherin, that is produced by aortic smooth muscle cells. It is the commonest form of human amyloid protein but unlike other amyloidogenic peptides it is not degraded by insulinase.

medium (*pl. media or mediums*) **1** the surrounding substance in which organisms or cells are studied or preserved. **2** the continuum in which particular chemical entities and their reactions are studied, commonly the solvent together with any nonreacting solutes. **3** any of the materials in which a chromatographic or an electrophoretic separation is effected. **4** the continuum through which electromagnetic radiation is considered to be transmitted. **5** *see culture medium.*

medium-chain acyl-CoA dehydrogenase deficiency the most common defect of mitochondrial beta oxidation in humans, due to deficiency of acyl-CoA dehydrogenase (*see beta-oxidation system*). It is characterized by hypoglycemic coma provoked by fasting, hepatic dysfunction, and sudden death. There is abnormal accumulation and urinary excretion of C₆–C₁₂ fatty acids and their dicarboxylic acids. Many mutations at the locus 1p31 cause the deficiency.

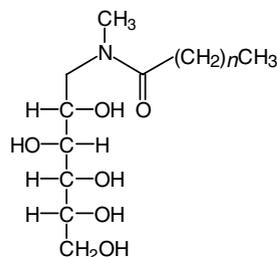

MEDLINE *see bibliographic database.*

medulla (*pl. medullas or medullae*) the innermost part of an organ, tissue, or structure; marrow, pith. —**medullary** *adj.*

MEF *abbr. for myocyte enhancement factor.*

mega- **1** *symbol:* M; an SI prefix denoting 10⁶ times. **2** a prefix used in computing to indicate a multiple of 2²⁰ (i.e. 1 048 576), as in megabyte. **3** a general prefix denoting large size.

Mega-8 or **Omega** the octanoyl amide of *N*-methylglucamine (i.e. 1-methylamino-1-deoxy-D-glucitol); a water-soluble, nondenaturing detergent (CMC = 58 mM) useful for membrane research. It is one of a series, which also comprises Mega-9, the nonanoyl derivative (CMC = 19–25 mM), and Mega-10, the decanoyl derivative (CMC = 6–7 mM).

Mega-8 *n* = 6
Mega-9 *n* = 7
Mega-10 *n* = 8

megabase *symbol:* Mb; a unit of length of a polynucleotide equal to 10⁶ base residues in a single-stranded polynucleotide or 10⁶ base pairs in a double-stranded polynucleotide.

megadalton *symbol:* MDa; a unit of mass equal to 10⁶ daltons.

megakaryocyte a large (diameter 40–150 μm), polyploid cell that gives rise to the blood platelets by budding of its cytoplasm. It contains, on average, four times the diploid number of chromosomes in a large, usually lobulated nucleus. Megakaryocytes are found in bone marrow, lung, and to a lesser extent in other tissues.

megalin *an alternative name for LRP2.*

megaloblastic anemia any of a group of disorders characterized by an abnormality of red cell development in the bone marrow. There is an accumulation of primitive cells, with failure of nuclear development, while cytoplasmic development, including hemoglobinization, continues; oval macrocytes appear in the blood. Vitamin B₁₂ or folate deficiency, or abnormality of vitamin B₁₂ or folate metabolism, is a frequent cause, but drug treatment (with antifolates, e.g. methotrexate, or drugs that interfere with DNA synthesis, e.g. cytarabine (β-cytosine arabinoside), hydroxyurea, AZT) or certain leukemias may also be causes.

megatomic acid *see tetradecadienoic acids.*

meiosis or **reduction division** a process by which the nucleus of a diploid cell divides twice with the formation of four daughter haploid cells, each containing half the number of chromosomes of the parent nucleus. Meiosis occurs during the formation of gametes from diploid cells and at the beginning of haplophase in those organisms that exhibit alternation of generations. Meiosis involves two rounds of cell division. Prophase in the first division proceeds as follows. Chromosomes first become visible as elongated threads during **leptotene**; by this time each chromosome has already replicated to form two identical sister chromatids. During **zygotene** each chromosome pairs with its homologue; the two become aligned and the **synaptonemal complex** develops between them. When synapsis is complete **pachytene** is said to have begun; it is during this stage that **crossing over** occurs between a chromatid in one partner and another chromatid in the homologous chromosome. The points of crossing over, or **chiasmata**, first become visible as the two chromosomes begin to separate in **diplotene**, when the synaptonemal complex dissolves. The final phase of prophase I, **diakinesis**, is the transition into metaphase I, which is analogous to mitotic metaphase and is followed by anaphase I and telophase I, producing two daughter cells each with one copy of each chromosome (each still made up of two sister chromatids). A second division quickly follows, comprising an interphase (without chromosome replication), and mitosis-like prophase II, metaphase II, anaphase II, and telophase II to separate the two chromatids in each chromosome. *Compare mitosis.* —**meiotic** *adj.*

MEK *abbr. for* 1 methyl ethyl ketone. **2** mitogen-activated ERK-activating kinase; a protein kinase with dual specificity for threonine and tyrosine. During intracellular signalling by insulin it phosphorylates these residues in MAP kinases (*see ERK*).

Mel-18 or **Zfp144** a gene, first identified in a melanoma, that en-

codes a nuclear RING finger protein. It is related to *Polycomb 4* of *Drosophila*, which controls expression of homeotic genes. The gene is widely expressed during mouse embryogenesis.

melanin any of the black or brown pigments of high molecular mass formed by the action of oxidase enzymes on phenols. They are widely distributed in plants and animals, are derived from tyrosine, and are usually bound to protein. Plant melanins are called **catechol melanins** because they yield catechol on alkali fusion; animal melanins, termed **eumelanins**, arise from the formal polymerization of indole-5,6-quinone and thus, in contrast to plant melanins, contain nitrogen. **Pheomelanin** is red and/or yellow and is derived from tyrosine and cysteine, as an alternative to eumelanin production in melanosomes. —**melanic** *adj.*

melanin concentrating hormone *abbr.*: MCH; a neuropeptide (19 amino acids, one disulfide bond) of the intermediate lobe of the pituitary gland of teleost fishes and of the lateral hypothalamus of mammals. Infused into mice it stimulates feeding behaviour. The precursor of mammalian MCH also contains a 13-residue peptide homologous to CRH, and a 19-residue peptide homologous to GHRH. The physiological role of MCH is unclear. It acts on a G-protein-coupled membrane receptor that activates phospholipase C.

melanocortin a generic term for either of the peptide hormones **melanotropin** or **corticotropin**, derived from their common precursor **proopiomelanocortin**. Although they have distinct functions (melanotropin in control of melanocyte growth and pigment formation, corticotropin in stimulating the adrenal cortex to produce glucocorticoids and aldosterone), they also share functions in, e.g., immunomodulation and antipyretic activity; because corticotropin can regulate melanocyte function, it is possible also to regard it as a melanotropin.

melanocortin receptor any of a family of G-protein-associated membrane receptors that on binding of ligand activate adenylate cyclase. Several types of receptor have been identified.

Melanocortin-1 receptor (*other names*: melanocyte-stimulating hormone receptor; melanotropin receptor) and **melanocortin-2 receptor** (*other name*: adrenocorticotrophic hormone receptor) are both located on melanocytes and adrenocortical tissue. **Melanocortin-3 receptor** and **melanocortin-4 receptor** are both located on brain, placental, and gut tissue, whereas **melanocortin-5 receptor** is expressed in brain but not melanocytes. Human ACTH receptor is 39% identical with the human MSH receptor. Receptors 1–3 and 5 respond to α -, β -, and γ -MSH and ACTH, melanocortin-4 receptor being specific to a common heptapeptide core sequence MGHFRWG. However, despite similarities in structure and action on melanocortin receptors, physiologically MSH has no ACTH-like activity. These are more closely related to the Δ^9 -tetrahydrocannabinol receptor (*see* **cannabinoid receptor**) than to other peptide and amine G-protein-associated receptors. Mutations that lead to deficiency of melanocortin-4 receptor lead to severe obesity in childhood.

melanocyte a type of pigmented cell that can synthesize and store **melanin** in melanosomes. Melanocytes occur in the skin and in the pigmented layer of the eye. *See also* **melanophore**.

melanocyte regulatory factor an alternative name for **melanotropin regulatory factor**.

melanocyte-stimulating hormone *abbr.*: MSH; any of three peptide hormones, α -MSH, β -MSH, and γ -MSH, produced primarily by the intermediate lobe of the pituitary gland, that cause dispersal of melanosomes in **melanophores** of poikilothermic vertebrates, but whose physiological function in mammals is not understood. Their sequences are all contained within that of **proopiomelanocortin** (the common precursor of corticotropin and β lipotropin). α -MSH is a tridecapeptide amide (usually acetylated on the N-terminal serine residue) that corresponds to residues 1–13 of corticotropin and has the same sequence in almost all animals studied. β -MSH (*formerly called intermedin*), not believed to be present in humans, corresponds to residues 41–58 of β lipotropin and shows greater structural variability. γ -MSH, a putative hormone, is a peptide of variable length that corresponds to part of the so-called cryptic region of proopiomelanocortin. *See also* **melanotropin**.

melanocyte-stimulating hormone receptor *see* **melanotropin receptor**.

melanocyte-stimulating-hormone regulatory factor or **melanocyte-stimulating-hormone regulatory hormone** an alternative name for **melanotropin-regulatory factor**.

melanocyte-stimulating-hormone release-inhibiting factor (*abbr.*: MSHIF or MSHRIF) or **melanocyte-stimulating-hormone release-inhibiting hormone** (*abbr.*: MSHIH or MSHRIH) an older name for **melanostatin**.

melanocyte-stimulating-hormone releasing factor (*abbr.*: MSHRF) or **melanocyte-stimulating-hormone releasing hormone** (*abbr.*: MSHRH). *See* **MSHRH**.

melanoliberin the recommended name for melanocyte-stimulating-hormone releasing hormone (*see* **MSHRH**).

melanophilin a protein found on the inner surface of the plasma membrane of melanocytes that, with the small GTPase Rab27a, forms a receptor for myosin-Va and mediates movement of melanosomes.

melanophore a type of **melanocyte** that occurs especially in the skin of poikilothermic vertebrates. The cell's contractile properties allow rapid internal translocation of melanosomes, thereby bringing about rapid adaptive changes in the skin coloration of such creatures.

melanopsin an opsin-based photopigment present in retinal ganglion cells of various animals (frog, mouse, rat). It colocalizes with pituitary adenylyl cyclase-activating peptide (PAPEP), and is a component of the photoreceptive system for circadian rhythms.

melanosome a type of cell organelle that occurs in **melanocytes** and contains tyrosinase and other enzymes required for synthesis of melanin. Melanosomes are specialized lysosomes, sharing with them many proteins unrelated to melanin synthesis.

melanostatin a peptide that inhibits release of melanotropin, and is identical with **neuropeptide Y**. *Other names*: melanotropin release-inhibiting factor (*abbr.*: MIF or MRIF); melanotropin release-inhibiting hormone (*abbr.*: MIH or MRIH); melanocyte-stimulating-hormone release-inhibiting factor (*abbr.*: MSHIF or MSHRIF); melanocyte-stimulating-hormone release-inhibiting hormone (*abbr.*: MSHIH or MSHRIH).

melanotransferrin *see* **transferrin**.

melanotropic or **melanotrophic** describing any agent that causes dispersal of melanosomes within **melanophores**.

melanotropin or (*formerly*) **melanotrophin** a generic term for any melanotropic hormone of the anterior pituitary that is derived from **proopiomelanocortin**. The term embraces α , β , and γ **melanocyte-stimulating hormones**. *See also* **melanocortin**.

melanotropin receptor any of a family of receptors that bind **melanotropins**. *See also* **melanocortin receptor**.

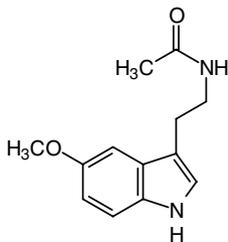

melanotropin-regulatory factor or **melanotropin-regulatory hormone** an older generic name for either **MSHRH** or **melanostatin**. *Other names*: melanocyte-regulatory factor; melanocyte-stimulating-hormone regulatory factor; melanocyte-stimulating-hormone regulatory hormone.

melanotropin release-inhibiting factor (*abbr.*: MIF or MRIF) or **melanotropin release-inhibiting hormone** (*abbr.*: MIH or MRIH) an older name for **melanostatin**.

melanotropin-releasing factor (*abbr.*: MRF) or **melanotropin-releasing hormone** (*abbr.*: MRH) *see* **MSHRH**.

MELAS *abbr.* for mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes; a mitochondrial disease of humans commonly associated with point mutations in mitochondrial DNA encoding a leucyl-tRNA.

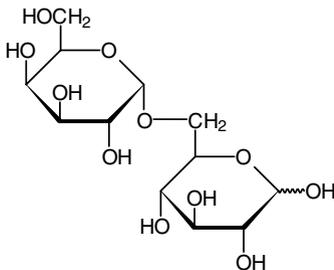

melatonin *N*-acetyl-5-methoxytryptamine; a neuroendocrine tryptophan derivative synthesized in the pineal gland from 5-hydroxytryptamine; its synthesis exhibits a circadian photoperiodism. In amphibia, it has an action opposite to that of **melanocyte-stimulating hormone**. It stimulates the aggregation of melanosomes in melanophores, thus lightening the skin. In mammals it seems to regulate circadian rhythms, sleep, and mood, and may have effects on the reproductive system. It acts through G-protein-associated membrane receptors of which type 1 inhibit adenylate cyclase, and type 2 activate phospholipase C. It is inactivated by 6-hydroxylation and is excreted in conjugated form. When used as a drug it is reputed to control jet lag.

melezitose the trisaccharide, *O*- α -D-glucopyranosyl-(1 \rightarrow 3)-*O*- β -D-fructofuranosyl-(2 \rightarrow 1)- α -D-glucopyranoside; a component of the sweet exudations from many plants and of the leaves of some trees after insect attack.

melibiase *see* glucosidase.

melibiose the disaccharide, 6-*O*- α -D-galactopyranosyl-D-glucose; it occurs as a constituent of the trisaccharide, **raffinose**, and in the exudates and nectaries of a number of plants.

melissyl an alternative name for **myricyl**.

melitriose *see* raffinose.

melittin a strongly basic, sulfur-free, hemolytic, 26-residue peptide amide, often formylated on its N-terminal glycine residue. It comprises 40–50% of the dry mass of the venom of the honey bee, *Apis mellifera*. The hemolytic activity of melittin appears to be related to the ordering of its amino-acid residues, which renders the polypeptide markedly surface active.

melting **1** the (reversible) act or process of liquefaction of a solid through the action of heat (or change in pressure). **2** the increase (reversible and usually fairly abrupt) of molecular mobility of lipids in a biological membrane or artificial lipid bilayer with increase of temperature above the transition temperature. **3** or **thermal denaturation** the transition (usually fairly abrupt but not necessarily reversible) of a biopolymer from a highly ordered to a less highly ordered state with increase in temperature. Examples are the heat-induced change from a helical to a random coil structure in a protein or a duplex nucleic acid. *See also* **localized melting**, **melting temperature**.

melting curve an alternative name for **thermal denaturation profile**.

melting point *abbr.*: m.p.; the temperature at which the solid and liquid phases of a substance are in equilibrium at a given pressure. Melting points are usually given for standard atmospheric pressure, i.e. 101 325 Pa.

melting temperature *symbol*: T_m or t_m or Θ_m ; the temperature at which a conformational transition brought about by change in temperature (e.g. of a macromolecule in solution) is 50% complete. For example, it is the temperature ($^{\circ}$ C) at which 50% of a target DNA sequence is hybridized to oligonucleotides present in molar excess. It follows therefore that $T_m = \Delta H_{ot} / \Delta S_{ot}$, where ΔH_{ot} and ΔS_{ot} are, respectively, the standard enthalpy difference and the standard entropy difference for the transition. In the denaturation of DNA the melting temperature is taken as the midpoint of the **helix-to-coil transition**.

MEM *abbr. for* **1** minimum essential medium. **2** minimum Eagle's medium.

memapsin2 *see* **secretase**.

membrane any thin sheet or layer, often separating two compartments. Membranes may be natural or artificial, and are sometimes soft and pliable. *See also* **cell membrane**, **semipermeable membrane**, **unit membrane**. —**membranous** *adj.*

membrane attack complex *see* **MAC** (def. 1).

membrane attack complex inhibition factor (*abbr.*: MACIF) or **CD59 glycoprotein precursor**; *other names*: MAC-inhibitory protein, protectin, membrane inhibitor of reactive lysis (*abbr.*: MIRL); a surface antigen of T cells that potently inhibits the membrane attack complex (*see* **MAC**). It is complexed with a GPI anchor.

membrane-bound describing any component that is not readily dissociable from preparations of cellular membranes *in vitro* and/or that appears to be an integral part of a membrane in an intact cell.

membrane-bound O-acyltransferase *abbr.*: MBOAT; a widely distributed superfamily of integral membrane proteins that have O-acyltransferase activity. They typically have 8–10 transmembrane segments and transfer organic acids (especially fatty acids) to the hydroxyl group of a membrane-embedded acceptor. MBOATs share a region of conserved polar residues within and adjacent to the membrane, and an invariant histidine within a hydrophobic sequence. Examples include **sterol O-acyltransferase** (yeast and human), **diacylglycerol O-acyltransferase** (mouse and *Arabidopsis*), and porcupine protein (*Drosophila*).

membrane channel a protein complex that specifically facilitates the passive diffusion of small molecules through a membrane; particularly applied to **ion channels**.

membrane electrode any electrode that incorporates a membrane in its structure, e.g. a glass electrode, an ion-exchange electrode, or an oxygen electrode.

membrane filter or **filter membrane** any membrane consisting of a thin polymeric structure with pores of a defined and very uniform size that is used for filtration; a disk or piece of such membrane.

membrane filtration the act or process of separating suspended particles from a liquid, or of separating macromolecules from their solvent, with a **membrane filter**.

membrane-intrusive describing a peptide loop, situated between two neighbouring transmembrane segments of an integral membrane protein, that is forced back into the membrane but without penetrating it. An example is the **P domain** of shaker-type subunits of ion channels.

membrane-organizing spike protein *see* **moesin**.

membrane osmometer *see* **osmometer**.

membrane potential the electric potential existing across any membrane arising from charges in the membrane itself and from the charges present in the media on either side of the membrane. Plant and animal plasma membranes maintain a potential, the cell interior being more negative than the exterior. In plants this arises mainly from the activity of electrogenic pumps, whereas in animals passive ion movements predominate in creating this potential. The resting potential varies from -20 mV to -200 mV according to cell type; for a neuron it is about -70 mV. In plants, **H⁺-transporting ATPases** pump protons out of the cell, thus maintaining a pH gradient across the plasma membrane. This is involved in symport of carbohydrates and amino acids into the cell. In animals, the Na⁺,K⁺-ATPase exchanges intracellular Na⁺ for extracellular K⁺, maintaining the high intracellular K⁺ concentration and low intracellular Na⁺ concentration. K⁺-leak channels in the plasma membrane allow K⁺ to escape until counteracted by the electrical potential and excess of intracellular negative charge that results. An electrochemical gradient across the mitochondrial inner membrane is created by proton-pumping cytochromes. *See also* **chemiosmotic coupling hypothesis**, **Nernst equation**.

membrane protein any protein that is normally closely associated with a cell membrane, owing to the properties of the protein and the method by which it is synthesized. **Integral proteins** contain hydrophobic regions that traverse the lipid bilayer; in some cases, the protein has only one such region, with hydrophilic domains on either side of the membrane; in other cases, where several such regions are present, a polypeptide may traverse the membrane several

times (*see* **seven-transmembrane-domain proteins**). Other proteins are bound to the membrane by a **gpi anchor**, and others by the hydrophobic moiety of a fatty-acyl group (*see* **myristoylation**) or a prenyl group (*see* **prenylation**). Other proteins may be more loosely attached, mainly by ionic forces (peripheral proteins).

Type I membrane proteins have a single (monotopic) transmembrane domain, with the C terminus on the cytoplasmic side. **Type II membrane proteins** have a single transmembrane domain with an N terminus that is cytoplasmic. **Type III membrane proteins** traverse the membrane several times (polytopic). **Type IV membrane proteins** are multimers of subunits that when assembled make a transmembrane channel. Proteins attached to the membrane only by covalently bound lipids are classified as **type V**, and those that are anchored by one or more transmembrane domains and also by a GPI anchor are designated **type VI**. The structures of only a few membrane proteins have been solved at high resolution (7 Å or better). Except for these it is not known whether the transmembrane domain is helical.

membrane receptor any protein, situated in or on a cell membrane, that binds extracellular signalling molecules (e.g. hormones, growth factors) and transduces the signal to produce intracellular effects.

membrane skeleton the protein network of an erythrocyte membrane, defined operationally as the insoluble residue that remains after extraction of either intact red cells or their isolated membranes with the nonionic detergent Triton X-100.

membrane teichoic acid any **teichoic acid** found in the protoplast of a bacterial cell as opposed to any found exclusively in the cell wall or in capsular material. Such substances commonly are glycerol teichoic acids, and they occur, covalently attached to lipid, in the cell membrane and probably also in mesosomes.

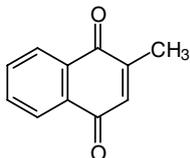

membrane transport any movement of substances across a (biological) membrane.

membrane type-serine protease 1 *see* **MT-SP1**.

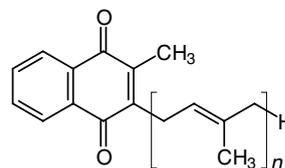

memory cell any of a population of long-lived **T** or **B lymphocytes** that have previously been stimulated by antigen, and make an accelerated response to that antigen if they encounter it again. Memory B cells carry surface immunoglobulin G as their antigen receptor; this is of higher affinity than on virgin lymphocytes. Memory T cells may be distinguishable by high expression of CD44.

MEN *abbr.* for multiple endocrine neoplasia; any of two distinct genetic syndromes in which multiple endocrine neoplasias occur. MEN1 is due to numerous loss-of-function mutations in the nuclear protein **menin**, with usually benign tumours of anterior pituitary, parathyroid, and enteropancreatic neuroendocrine cells. MEN2 is due to gain-of-function mutations in the *ret* protooncogene, which is expressed as a cell surface glycoprotein that is a member of the receptor protein kinase family. It usually presents as medullary thyroid carcinoma, often associated with pheochromocytoma or parathyroid adenoma.

menadione 2-methyl-1,4-naphthalenedione; 2-methyl-1,4-naphthoquinone; vitamin K₃; a synthetic naphthoquinone derivative possessing the physiological properties of **vitamin K**.

menaquinone *abbr.*: MK; the class name for a series of 2-methyl-3-all-*trans*-polyprenyl-1,4-naphthoquinones, also known as vitamins K₂ (*see* **vitamin K** for function). They are antihemorrhagic vitamins, present in bacteria, and possess 1–13 prenyl residues, the number of prenyl residues being indicated by a suffixed Arabic number, e.g. menaquinone-6 (MK-6; *also known as* **farnoquinone**). [From methyl naphthoquinone.]

menaquinone

Mendelian 1 of or relating to Gregor Johann Mendel (1822–84), Austrian monk and botanist, or following his laws of heredity. **2** one who adheres to or supports **Mendel's laws of heredity**.

Mendelian population a community of sexually interbreeding individuals.

Mendel's laws of heredity the principles of heredity proposed by Gregor Johann Mendel (1822–84), Austrian monk and botanist, on the basis of his researches on hybridization of peas to explain the behaviour of factors (now called genes) that govern the transmission of inherited characters from generation to generation. On the basis of modern knowledge, Mendel's first law, the **law of segregation**, states that every somatic cell carries a pair of allelic genes for each character and that the two genes in each pair separate during meiosis so that each gamete carries only one gene from each pair. Mendel's second law, the **law of independent assortment**, states that the separation of members of any pair of allelic genes occurs independently of every other pair provided they are not linked.

menin a ubiquitously expressed nuclear protein (human, 610 amino acids) that contains two nuclear localization signals at the C-terminus. It binds and inhibits the transcription factor JunD and may be a tumour suppressor. Numerous mutations are associated with the autosomal dominant multiple endocrine neoplasia type 1 (MEN1). *See* **MEN**.

meniscus (*pl.* **menisci**) the curved upper surface of a liquid column that is concave when the containing walls are wetted by the liquid (contact angle <90°) or convex when not (contact angle >90°), sometimes extended to include a flat surface (contact angle = 90°). —**meniscoid** *adj.*

meniscus depletion (sedimentation equilibrium) method or **Yphantis method** a variant of the sedimentation equilibrium method for determining the relative molecular mass of a macromolecule in which centrifugation is effected at a speed high enough to render the concentration of the solute at the meniscus essentially zero; the concentrations of solute along the length of the cell are proportional to the difference in refractive index at any point from that at the meniscus. The method is especially useful for monodisperse systems.

Menkes ATPase *see* **Menkes disease**.

Menkes disease or **kinky-hair syndrome** or **steely-hair syndrome** a rare X-linked disorder characterized by cerebral and cerebellar degeneration, abnormalities of connective tissue, and kinky hair. It results from mutations in the gene for the Menkes ATPase, a copper transporter involved in the intestinal absorption of copper. [After John H. Menkes (1928–), US neurologist.]

menopausal gonadotropin or **human menopausal gonadotropin** (*abbr.*: hMG or HMG) *another name for* **menotropin**.

menotropin or **menotrophin** *other name*: human menopausal gonadotropin; *abbr.*: hMG or HMG; a gonadotropin with **follicle-stimulating hormone** and **luteinizing hormone** activity, isolated from the urine of postmenopausal women and used to stimulate ovulation in infertility. One proprietary name is Pergonal.

MEP *abbr.* for major excreted protease; *see* **cathepsin L**.

meprin A EC 3.4.24.18; *other names*: endopeptidase-2; endopeptidase MEP-1; a type 2 transmembrane serine protease of kidney and intestinal brush borders. Zinc is a cofactor. It catalyses the hydrolysis of proteins and peptides on the C-terminal side of hydrophobic residues, and is a homotetramer of α or β subunits.

meq or **mEq** *symbol* for milliequivalent (use deprecated, mmol recommended).

mer or **constitutional unit** the repeating unit of a polymeric molecule.

+mer *suffix forming nouns (in chemical nomenclature)* denoting specific kinds or classes of polymer (e.g. hexamer, oligomer) or isomer (e.g. enantiomer, epimer, tautomer). —**+meric** *adj.*; **+merism** *n.*

mer the symbol for genes of the *mer* operon whose products confer (or regulate) mercury resistance. For example, the bacterium *Serratia marcescens* has several *mer* products. (1) MerA is mercury(II) reductase (EC 1.16.1.1); *systematic name*: Hg:NADP⁺ oxidoreductase; one of the very rare enzymes with metal substrates, it catalyses the reduction by NADPH of Hg²⁺ to form Hg and NADP⁺. It is a flavoprotein (FAD) with redox-active disulfide bonds, and is responsible for volatilizing mercury as Hg(0). (2) MerB is alkylmercury lyase (EC 4.99.1.2); *systematic name*: alkylmercury mercuric lyase; it catalyses a reaction between RHg⁺ and H⁺ to form RH and Hg²⁺. This enzyme cleaves the carbon–mercury bond of organomercurials and the Hg²⁺ product is detoxified by MerA. (3) MerR is a **helix-turn-helix** regulatory protein. In the absence of mercury, MerR represses transcription by binding tightly to the *mer* operator region; when mercury is present the dimeric complex binds a single ion and becomes a potent transcriptional activator, while remaining bound to the *mer* site. *mer* operons are encoded by a number of plasmids that have been cloned into *Escherichia coli*, e.g. Tn21 of *Shigella flexneri*, Tn501 from *Pseudomonas aeruginosa* (these two lack the organomercury lyase gene and so confer resistance only against inorganic mercury salts), and pDU1358 from *S. marcescens* (which includes *merB* and thus encodes a broad-spectrum *mer* operon).

mer+ *prefix (in coordination compound nomenclature)* denoting a **meridional** (def. 2) arrangement of ligands.

MER *abbr. for medium reiteration frequency repeat; other usage*: medium reiteration frequency interspersed repetitive elements (*abbr.*: MER elements). They consist of repeated base sequences in eukaryotic genomes. More than fifty human repetitive families are known, of which most represent MERs. The latter have copy numbers per genome ranging from hundreds to thousands, and length ranging from tens to a few hundred base pairs. They are of unknown function, but some may play a role in regulation of gene expression and others may affect genome stability and gene rearrangements.

mercapt+ *a variant form of mercapto+* (sometimes before a vowel).

mercaptan *an old name for thiol.*

mercapto+ or (sometimes before a vowel) **mercapt+** *comb. form (in chemical nomenclature)* indicating the presence of an unsubstituted thio group, –SH.

2-mercaptoethanol HO–CH₂–CH₂–SH; 2-hydroxyethylmercaptan; a sulfhydryl reducing agent often used in buffers to maintain protein sulfhydryl groups in the reduced state.

mercaptapurine or **6-mercaptapurine** *abbr.*: 6-MP; *symbol*: Shy; thiohypoxanthine; 6-purinethiol; an immunosuppressive and anti-neoplastic drug useful in organ transplantation and in the treatment of some leukemias. It is a substrate for guanine-hypoxanthine phosphoribosyltransferase, which converts it to **6-mercaptapurine ribonucleoside** (or 6-thioinosine; *symbol*: Sno or M or sl).

mercapturic acid any S-alkyl- or S-aryl-N-acetylcysteine; such compounds are formed as detoxification products in mammals. The initial reaction involves conjugation with the thiol group of glutathione catalysed by a **glutathione transferase** to form the S-acyl-glutathione (*see* **radyl**). Glutamic acid and glycine are then removed in the kidney, and the resulting mercapturic acid is excreted in the urine.

mercurate to treat or mix with mercury; to introduce mercury into an organic compound. —**mercuration** *n.*

mercurial **1** of, containing, like, or pertaining to mercury. **2** any compound containing mercury, especially one used in medicine and/or agriculture; *see also* **organomercurial**.

mercuric perchlorate Hg(ClO₄)₂; a substance used in solution to trap ethylene.

mercury II reductase EC 1.16.1.1; product of the *Serratia marcescens merA* gene (*see mer*).

mercury-vapour lamp or **mercury-discharge lamp** or (*informally*)

mercury lamp a lamp that emits bluish-green light rich in ultraviolet radiation, produced by passing an electric discharge through mercury vapour, often at low pressure. It is useful for provoking or investigating fluorescence, as a light source for a **polarimeter**, and as a source of sterilizing radiation.

meridian **1** any line on the surface of a sphere or spheroid that is orthogonal to its equator, or any corresponding line in a projection of part of the surface of a sphere or spheroid onto a planar or cylindrical surface. **2** in a fibre diagram produced by X-ray diffraction, the vertical axis on the film that corresponds to the *z* axis in reciprocal space.

meridional **1** of, along, pertaining to, or resembling a meridian. **2** describing the geometrical isomer of a coordination compound of octahedral configuration in which three ligands in the coordination sphere are in such a relationship that one is *cis* to the two others, which are themselves *trans*. Such an isomer is designated by prefixing *mer-* to the chemical name.

meristem a region of tissue in a plant that is composed of one or more undifferentiated cells that are capable of undergoing mitosis and differentiation, and thereby of effecting growth and development of a plant by giving rise either to more meristem or to specialized tissue. In vascular plants, meristems may be apical (located at the tips of growing roots and shoots) or lateral (arranged circumferentially and constituting the cambium). —**meristematic** *adj.*

merlin or **neurofibromatosis type 2 (tumour suppressor)** (*abbr.*: NF2) or **Schwannomin** a membrane-stabilizing protein from fetal brain and other tissues, such as kidney, lung, and breast. It is similar to **ezrin** and **talin**. It is a tumour suppressor of the **TERM** family. In humans, it is encoded by a gene on chromosome 22q12.

mero+ *comb. form* denoting part, partly, or partial.

merocrine **1** describing a type of secretion that does not entail disintegration of the secretory cell. **2** describing a gland made up of such cells. *Compare* **apocrine**, **eccrine**, **holocrine**.

merodiploid a haploid organism that is diploid for a small region of the chromosome, i.e. a partial diploid.

meromyosin either of the two fragments, **heavy meromyosin** and **light meromyosin**, produced by brief treatment of myosin with trypsin or certain other proteases.

MEROPS *see* **specialist database**.

mero-receptor the smallest subunit of a receptor for a (steroid) hormone that contains an intact hormone-binding site. The biological significance of mero-receptors is unclear; they may be artefacts of experimental cellular disruption or products formed by proteolysis associated with the termination of (steroid) hormone action.

merosin a tissue-specific-basement-membrane protein, and the M chain of **laminin**. It is covalently associated with laminin B chains and, like laminin, is cruciform. It shares similarity with the C-terminal part of the laminin A chain.

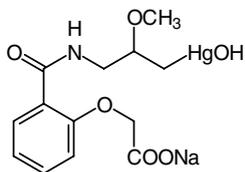

merozygote any bacterial cell that is partly diploid and partly haploid, formed by conjugation, transduction, or transformation. It contains one complete genome, that of the recipient organism, and a fragment of a second genome, derived from the donor.

MERRF *abbr. for* myoclonus epilepsy with ragged-red fibres; a mitochondrial disease of humans characterized by abnormally shaped mitochondria (which sometimes contain paracrystalline inclusions) in skeletal muscle fibres. It is commonly associated with point mutations in the mitochondrial DNA for lysyl-tRNA.

Merrifield method *an alternative name for* **solid-phase peptide synthesis**. [After Robert Bruce Merrifield (1921–), US peptide chemist and biochemist.]

Merrifield resin a beaded reactive synthetic resin designed for use in the Merrifield method (i.e. **solid-phase peptide synthesis**).

mersalyl *pharmaceutical name of* sodium *o*-[3-(hydroxymercuri)-2-methoxypropyl]carbamoyl phenoxyacetate; a mercury-containing derivative of salicylamide. It is a diuretic drug useful as an inhibitor of the exchange of phosphate and hydroxide ions across the inner mitochondrial membrane.

mes+ a variant form of **meso+** (sometimes before a vowel).

Mes or **MES** *abbr.* for and *trivial name* of 2-(*N*-morpholino)ethanesulfonic acid; a **Good buffer substance**, pK_a (20°C) = 6.15.

mesaconic acid (*E*)-2-methyl-2-butenedioic acid; methylfumaryl acid; an intermediate in the fermentation of glutamate to acetyl-CoA by *Clostridium tetanomorphum*.

mescaline 3,4,5-trimethoxyphenylethylamine; a hallucinogenic and sympathomimetic drug isolated from the flowering heads of the mescal cactus (*Lophophora williamsii*), also known as peyote or peyotle.

Meselson-Stahl experiment a landmark experiment, reported by Meselson and Stahl in 1958, that provided convincing evidence for semiconservative replication of DNA in bacteria. Cultures of *Escherichia coli* were grown in a medium containing $^{15}\text{NH}_4\text{Cl}$ (96.5% isotopic purity) as sole nitrogen source for many generations so as to label the DNA with heavy nitrogen. The cells were then transferred to a medium containing $^{14}\text{NH}_4\text{Cl}$ and the culture sampled for several subsequent generations. Cell lysates were subjected to density-gradient centrifugation and the positions of the DNA bands in the gradients located by UV absorption. Initially the DNA appeared as a single band corresponding to DNA containing heavy nitrogen; subsequently a second band of DNA, containing equal amounts of heavy and light nitrogen, appeared, and one generation after transfer to natural ammonium chloride all the DNA was this hybrid form. After two generations only hybrid and natural DNA was present. Furthermore, the separated strands of this hybrid DNA proved to contain all heavy nitrogen or all normal nitrogen only. [After Matthews Meselson (b. 1930), US molecular biologist, and Franklin William Stahl (b. 1929), US geneticist.]

mesenchyme immature, unspecialized connective tissue found in the early embryo of animals. It consists of cells embedded in a tenuous extracellular matrix. —**mesenchymal** *adj.*

mesentery 1 the double-layer fold of peritoneum serving to hold the abdominal viscera in position. **2** any of the muscular partitions extending inwards from the body wall in coelenterates. —**mesenteric** *adj.*

MeSH *abbr.* for medical subject headings.

Me₃Si *symbol* for the trimethylsilyl group.

meso describing a bridging atom or group between two rings in a polycyclic molecule.

meso+ or (sometimes before a vowel) **mes+** *comb. form* denoting middle, or intermediate.

meso- *abbr.*: *ms-*; *prefix* (in chemical nomenclature) designating a substance whose individual molecules contain equal numbers of enantiomeric groups, identically linked, but no other chiral group; i.e. a substance whose molecules are optically inactive because of internal compensation; e.g. *meso*-compound, *meso*-cystine. *Compare racemo-*.

meso-carbon atom a term suggested for any prochiral carbon atom in an organic molecule whose valence bonds are linked to two identical groups, *a*, and to two other dissimilar groups, *b* and *d*. The resulting molecule, *Caabd*, has a plane of symmetry and thus the carbon atom is not chiral; however, the two *a* groups are not geometrically equivalent but bear a mirror-image relationship to each other, and they may react at different rates with chiral reagents or in enzymic reactions. The term is now obsolete. See **prochiral**.

mesoderm the middle of the three primary germ layers of a triploblastic animal embryo, lying between the ectoderm and endoderm. It is the source of bone, muscle, connective tissue, the inner layer of the skin, and other structures. —**mesodermal** *adj.*

meso-inositol a former name for *myo*-inositol.

mesomeric effect (in chemistry) an experimentally observable ef-

fect (on reaction rates, etc.) of a substituent caused by the overlap of its *p*- or π -orbitals with the *p*- or π -orbitals of the rest of the molecular entity, **resonance** (def. 2) (or mesomerism) being thereby introduced into, or extended within, the molecular entity in question.

Compare inductive effect.

mesomerism (in chemistry) a term used to imply that the correct representation of the structure of a particular molecular entity is intermediate between two or more formal valence-bond representations (known as **contributing structures**); **resonance** (def. 2). —**mesomeric** *adj.*

mesomorphic 1 (in chemistry) existing in, designating, or pertaining to an intermediate state between a true liquid and a true solid that exists in a **liquid crystal**. **2** (in biology) having a form, size, or structure that is average, normal, or intermediate between extremes.

mesophase any phase of matter intermediate between a true liquid and a true solid that exists in a **liquid crystal**.

mesophil or **mesophile** any organism that thrives at moderate temperatures, between 20 and 40°C. —**mesophil**, **mesophile**, or **mesophilic** *adj.*

mesophyll the internal parenchyma of a foliage leaf between the two epidermal layers; it is usually photosynthetic. —**mesophylllic** *adj.*

mesophyte any plant requiring moderate amounts of water for optimum growth. —**mesophytic** *adj.*

mesopore any pore (in a gel or porous solid) intermediate in size between a micropore and a macropore, i.e. of width in the range roughly 2.0–50 nm. —**mesoporous** *adj.*

mesosecrin a glycoprotein, M_r 46 000, secreted by human mesoderm-derived and endothelial cells in culture.

mesosome an intracellular, often complex, membranous structure found in many bacteria and probably formed by invagination of the plasma membrane. It is more complex and larger in Gram-positive organisms than in Gram-negative ones. Its function is unclear. —**mesosomal** *adj.*

mesothelium (*pl.* **mesothelia**) a layer of flat cells derived from mesoderm and found lining various body cavities. —**mesothelial** *adj.*

mesotocin [Ile^8]oxytocin; a neurohypophyseal hormone present in some nonmammalian vertebrates, so-named because it is intermediate in structure between **isotocin** and **oxytocin**. It may represent an ancestral molecule, which has been preserved in these groups of vertebrates but has undergone a single residue replacement in mammals.

mesotrophic describing an environment providing a moderate amount of nutrients.

message 1 a specific piece of information, or something containing information, that is transmitted from a donor to a recipient by some means or agent. **2** a jargon term used, sometimes without an article, as the name of a substance, to denote the particular **messenger RNA** (mRNA) of interest in a specified context, or any preparation containing that mRNA. **3** the segment of mRNA (or any particular segment of a polycistronic mRNA) that consists of a sequence of codons carrying the information determining the sequence of amino-acid residues of a specific polypeptide to be synthesized at a ribosome. **4** the part of the information contained within the amino-acid sequence of a hormonal polypeptide, or of its biosynthetic precursors, that elicits a specific physiological response to the hormone. *Compare address* (def. 2).

message-dependent (of a partially purified, cell-free, protein-synthesizing system) capable of a significant response to added mRNA.

message sequence or **message region** the segment (or segments) of the complete sequence of amino-acid residues of a molecule of a hormonal or prohormonal polypeptide in which the **message** (def. 4) resides. *Compare address sequence.*

messenger 1 something, or someone, that bears or carries a **message** (def. 1), or that is able to do so. **2** a molecule or substance that carries genetic information; see **messenger RNA**. **3** a molecule or substance that carries physiological instructions; a **rheosome**. *See also chemical messenger, first messenger, second messenger.*

messenger ribonucleoprotein *abbr.*: mRNP; any complex of

messenger RNA (mRNA) and protein. Included are: nuclear ribonucleoprotein that contains mRNA sequences; cytoplasmic ribonucleoprotein that is associated with polyribosomes; and free cytoplasmic ribonucleoprotein particles, also known as **informosomes**.

messenger RNA or **template RNA** *abbr.*: mRNA; a class of naturally occurring RNA molecules that carry the information embodied in the genes of DNA to the ribosomes, where they direct protein synthesis. Molecules of mRNA are single-stranded, relatively short-lived, and formed by the process of **transcription** from the template strand of genomic DNA. They carry genetic information in the form of a succession of **codons**. Mature eukaryotic mRNAs contain a 5' cap and a 3' poly(A) tail. At the ribosomes, by the process of **translation**, they orchestrate the synthesis of the corresponding polypeptide(s). The plus strand of certain RNA viruses can act as messenger RNA without transcription, as can a synthetic polyribonucleotide. The primary transcript of DNA is often referred to as **hnRNA**, which contains the **introns** that have to be removed by excising and splicing together the **exons** to form the mature mRNA. mRNA may also undergo 'editing' whereby some bases are changed. *See also* mRNA binding site, splicing.

messenger-RNA-interfering complementary RNA *abbr.*: micRNA; *an alternative name for antisense RNA*.

Messing vector any one of certain cloning vectors derived from bacteriophage M13 by insertion of a synthetic multipurpose cloning site and which are especially suitable for the cloning and rapid sequence determination of small (≈ 500 base pair) fragments of DNA. These have developed into the **pUC vectors**. [After Joachim Messing (1946–).]

met+ a variant form of **meta+** (usually before a vowel or letter h).

Met symbol for a residue of the α -amino acid L-methionine (alternative to M).

MET a gene, first identified in an *N*-methyl-*N'*-nitrosoguanidine-treated cell line, that encodes a receptor tyrosine kinase with disulfide-linked α and β subunits. The receptor binds **hepatocyte growth factor** and undergoes autophosphorylation of the cytoplasmic domain. Cells co-transfected with **MET** and **HGF** are highly tumorigenic. Germ-line missense mutations lead to a familial form of renal cancer. *See also* hepatocyte growth factor receptor.

meta+ or (*before a vowel or letter h*) **met+** prefix **1** indicating alteration, alternation, or change of condition or position; after, distal to, behind, beyond; more highly specialized form of **2** (*in inorganic chemistry*) denoting the least hydrated acid of a series of oxoacids formed from any one of certain anhydrides, or the anion or a salt formed from such an acid; *Compare* **ortho+** (def. 2), **pyro+** (def. 2). It is now approved only for the polymeric acids: metaphoric acid, $(\text{HBO}_2)_n$, metaphosphoric acid, $(\text{HPO}_3)_n$, and metasilicic acid, $(\text{HSiO}_3)_n$; and for anions and salts of these acids (*but see* **metabisulfite**). **3** (*in organic chemistry*) distinguishing a particular polymeric form of the substance named, e.g. metaldehyde, metaformaldehyde.

meta- symbol: *m-*; prefix (*in organic chemical nomenclature*) denoting the isomer of a disubstituted monocyclic aromatic compound in which the substituents are separated by one intervening unsubstituted ring-carbon atom. *Compare* **ortho-**, **para-**.

meta-analysis a quantitative systematic review in which the results of many studies dealing with the same topic are combined. It is used in the study of multifactorial diseases.

metabisulfite *an old name, still frequently used, esp. in commerce*, for inorganic salts of the general formula $\text{M}_2\text{S}_2\text{O}_5$, where M is a monovalent metallic element.

metabolic of, pertaining to, occurring in, produced by, or liberated during **metabolism**. —**metabolically** *adv.*

metabolic acidosis any clinical condition in which hydrogen ions accumulate in the blood plasma through an excessive production of acidic metabolites (as in ketoacidosis or lactic acidosis), the excessive ingestion of acids, or a defect in the excretion of hydrogen ions by the kidneys.

metabolic activation **bioactivation**, usually with particular reference to the conversion of procarcinogens to carcinogens in the body.

metabolic alkalosis any clinical condition in which there is a deficiency of hydrogen ions in the blood plasma caused by the excessive

ingestion of alkalis, extrarenal loss of acid (as with vomiting), or therapy with diuretic agents.

metabolic balance *see* **balance** (def. 1).

metabolic block the complete or partial interruption of a specific reaction in a metabolic pathway caused by the absence or greatly reduced activity of the enzyme catalysing that reaction (for genetic reasons or due to the action of a specific agonist). The consequences of a metabolic block include: (1) the complete or partial absence of the final product of the pathway; (2) the accumulation of a metabolic intermediate of the pathway before the block, for which no significant alternative pathway exists; (3) the accumulation of products of an alternative, normally minor, metabolic pathway. *See also* **inborn error of metabolism**.

metabolic code a model for the evolution of biological regulation and the origin of hormone-mediated intercellular communication. It is characterized by a set of symbols and their corresponding domains. A **symbol** is an intracellular molecule, e.g. a hormone or other messenger, that indicates to the cell the existence of a particular state of the environment, e.g. lack of glucose or of amino acids. The symbol regulates a diverse set of biochemical events and reactions in the cell, the nature and number of which are the **domain** of that symbol.

metabolic compartmentation or **metabolic compartmentalization** the concept that certain metabolic reactions occur in separate compartments of the cell (or organism) and are therefore not necessarily in equilibrium with each other.

metabolic control *an alternative term for metabolic regulation*.

metabolic cycle any closed sequence of metabolic reactions in which an end product is a reactant in the initiation of the cycle, e.g. the **tricarboxylic acid cycle**.

metabolic disease any disease caused by a recognizable abnormality of metabolism.

metabolic flux the rate of passage of material, or of a specified substance or molecular fragment, through a given metabolic pathway.

metabolic map a diagram representing the sequence and relationships of enzyme-catalysed reactions in metabolism. It typically consists of the names and/or structures of metabolites, connected by arrows representing enzyme-catalysed reactions.

metabolic pathway any series of connected (enzymic or other) reactions occurring in a cell or organism, whether anabolic, catabolic, or amphibolic.

metabolic pool the sum total of all the different amounts of a given substance, group of similar substances, or specified molecular fragment, irrespective of their distribution in a cell, organ, tissue, or organism, that are in complete equilibrium with each other in regard to participation in a specified set of metabolic reactions.

metabolic quotient symbol: Q_x ; a measure of the rate at which a given substance (x) is taken up by, or discharged from, a cell, organ, tissue, or organism.

metabolic rate the rate of metabolism of an animal measured under given conditions. It may be determined from the dioxygen consumption and carbon dioxide (and urinary nitrogen) excretion, or from the total energy output of the animal. *Compare* **basal metabolic rate**.

metabolic reconstruction the process of modelling the metabolism of an organism (e.g. using biochemical, sequence, and phenotypic data) in order to identify which pathways are present and which genes are involved in which functional roles.

metabolic regulation the coordinated action of the many systems that control the activity of metabolic pathways. The systems embrace gene regulation and control of protein biosynthesis, as well as the control of the rate of enzyme reactions by phosphorylation of the enzyme protein or by the action of allosteric effectors. The action of second messengers is important in the transduction of signals from outside a cell to the interior.

metabolic state (of mitochondria) *an alternative term for respiratory state*.

metabolic turnover the continual exchange of cellular components by degradation and synthesis. Even for cell components for which the content and composition remain relatively constant, a continuous breakdown and resynthesis of individual molecules is occurring.

metabolism 1 the totality of the chemical reactions and physical changes that occur in living organisms, comprising **anabolism** and **catabolism**. **2** the totality of the chemical reactions and physical processes undergone by a particular substance, or class of substances, in a living organism.

metabolite any substance, either endogenous or exogenous, that is formed or changed by metabolism. *See also* **primary metabolite**, **secondary metabolite**.

metabolize or **metabolise 1** to affect by metabolism. **2** to effect metabolism. —**metabolizable** or **metabolisable** *adj.*

metabolome the universe of low-molecular-weight metabolites present in cells in a particular physiological or developmental state.

metabolomics the quantitative analysis of all the small-molecular-weight metabolites present inside a cell (or other sample).

metabolon a supramolecular complex of consecutively acting metabolic enzymes and cellular structural elements.

metabotropic describing a type of receptor (e.g. certain **glutamate receptors**) that mediates its effects by activation of enzymes, especially **adenylate cyclase** or the **phosphatidylinositol cycle**, in distinction from receptors that regulate ion channels. *Compare* **ionotropic**. *See also* **excitatory amino-acid receptor**.

metachromasia or **metachromasy** or **metachromatism 1** the property exhibited by certain cationic (i.e. basic) dyes of shifting their absorption spectra towards shorter wavelengths in the presence of substances with appropriately arranged anionic groups. **2** the property exhibited by some biological structures or materials, when treated with certain cationic (basic) dyes, of staining with a different colour from that of the dye used. Biological materials showing metachromasia include heparin, chondroitin sulfate, sulfatides, gangliosides, and polyphosphates. —**metachromatic** *adj.*; **metachromatically** *adv.*

metachromatic granule any cytoplasmic granule that exhibits metachromasia (def. 2). **Volutin granules** are an example.

metachromatic leukodystrophy any of a group of hereditary diseases of humans characterized by disintegration of myelin and the accumulation of **metachromatic lipid** – galactosyl sulfatide (cerebroside sulfate) – in the white matter of the central nervous system, in peripheral nerves, and in some visceral organs. It is mainly caused by mutations in the gene for the lysosomal enzyme arylsulfatase A (locus 22q13.31-qter). The disorder is characterized clinically by progressive paralysis and dementia, usually in the first few years of life, and is transmitted as an autosomal recessive trait. *See also* **saposin**.

metachromism *see* **metachromasia**.

metadrenaline *an alternative name for* **metanephrine**.

metagon a stable, virus-like RNA particle postulated to occur in certain mate-killer strains of *Paramecium aurelia*, in which it acts like messenger RNA.

metahalone any of a class of metaphase inhibitors having the general formula 5-halopyridine-2-one. [From meta(phase) halone.]

metakentrin *an obsolete name for* **luteinizing hormone**.

metal 1 any of a large class of chemical elements that, with certain exceptions, are ductile, malleable solids with a characteristic lustre, are good conductors of electricity and heat, and generally form simple cations. **2** any substance or material consisting entirely or predominantly of one or more **metals** (def. 1). **3** consisting of made of metal. —**metallic** *adj.*

metal-chelate affinity chromatography a form of **affinity chromatography** in which immobilized weak bases such as imidazole coordinated with ions such as Ni²⁺ are used to concentrate recombinant proteins bearing **His-tags**.

metal-ion buffer a **buffer** (def. 1, 2) for metal ions. It comprises a solution of a metal salt, with a suitable complexing agent. The concentration of free metal ions is maintained by the equilibrium with an excess of the complexed form.

metallo+ *comb. form* denoting metal, or characterized by the presence of metal.

metalloantigen any metal-labelled antigen for use in a **metalloimmunoassay**.

metallocarboxypeptidase *recommended generic name for any carboxypeptidase* of the sub-subclass EC 3.4.17, for which a bivalent cation is an essential component of the catalytic mechanism.

metallocene *the generic name for* π -bonded bis(η -cyclopentadienyl) coordination compounds of certain metals, e.g. ferrocene, bis(η -cyclopentadienyl)iron, [Fe(C₅H₅)₂].

metallochaperone any of a family of homologous proteins that bind and transport specific metals in the cytoplasm to their sites of utilization. They contain a metal-binding Cys–X–X–Cys motif within a four-stranded antiparallel beta sheet below two alpha helices. Six copies of this motif are present in the N-terminal region of Menkes and Wilson ATPases of the *trans* Golgi network. In yeast and human cells three metallochaperones are required to deliver copper to the Golgi apparatus, mitochondria, and cytosol respectively.

metallochromic describing a dye, indicator, or stain that exhibits a distinctive colour change when complexed with metal ions; the colour change is often specific for a particular metal.

metalloendopeptidase *recommended generic name for any endopeptidase* of the sub-subclass EC 3.4.24, for which a bivalent cation is an essential part of the catalytic mechanism.

metalloenzyme any enzyme that is a **metalloprotein**.

metallohapten any metal-labelled hapten for use in a **metalloimmunoassay**.

metalloimmunoassay a form of **immunoassay** in which ions of an appropriate transition metal, tightly complexed to the antigen or hapten in question, are used as the distinguishable label. The amount of metal present in the free and antibody-bound forms is determined by a suitable analytical method such as emission, absorption, or fluorescence spectrometry.

metallopeptidase *see* **metallocarboxypeptidase**, **metalloendopeptidase**. **metalloporphyrin** any compound formed by chelation of a porphyrin with a metal ion, e.g. hemoglobins (with iron), cytochromes (with iron), and chlorophylls (with magnesium).

metalloprotease *a former name for* metalloendopeptinase (*see also* **metallocarboxypeptidase**, **matrix metalloproteinase**).

metalloprotein any protein containing one or more molecular proportions of a metal bound to it, either directly or as part of a prosthetic group.

metalloproteinase *see* **metallocarboxypeptidase**, **metalloendopeptidase**.

metallo-selenonein a synthetic analogue of the copper metallothionein peptide of *Neurospora crassa* that contains selenocysteine residues in place of cysteine.

metallothionein any of a group of small proteins with extraordinarily high contents both of one or more metals (cadmium, copper, zinc) and of cysteine. They occur widely, from microorganisms to humans, and have highly conserved structures. Mammalian metallothioneins are of 6.8 kDa, consist of 61 amino-acid residues, including 20 cysteine residues, and contain about 7 g atoms of metal per molecule. The apoprotein may be termed **thionein**.

metaprotein *an old term for* the products formed by acid or alkaline hydrolysis of proteins that are soluble in weak acids or alkalis, but insoluble in neutral solutions.

metal proteinase *a former name for* metalloproteinase (*see* **metallocarboxypeptidase**, **metalloendopeptidase**).

metal response element *abbr.*: MRE; a sequence in the promoter region of metallothionein genes that respond to the presence of metals. *See also* **response element**.

metal response element binding protein *abbr.*: MREBP; a mammalian protein that activates basal and heavy metal-induced transcription of metallothionein genes by binding to the metal response element in their promoter regions. MREBP1 contains a DNA-binding region of six C2H2 zinc fingers and three functional activation domains. Knockout of the mouse gene results in death of embryos with variable degrees of liver damage.

metamer (*in chemistry*) *a former term for* any one of two or more **constitutional isomers** that are of the same chemical class, e.g. ethylamine, CH₃–CH₂–NH₂, and dimethylamine, CH₃–NH–CH₃.

metamere (*in morphology*) any of the linearly arranged similar body segments in animals that exhibit **metamerism** (def. 2); a somite.

metameric 1 (*in chemistry*) of or pertaining to a **metamer**; pertaining to the phenomenon of, or displaying **metamerism** (def. 1). **2** (*in morphology*) of, or pertaining to, a **metamere**; consisting of metameres; segmented; of, or pertaining to, **metamerism** (def. 2).

metamerism 1 (*in chemistry*) the occurrence as **metamers** of two or more chemical substances of the same molecular formula. **2** (*in morphology*) the condition of an animal body characterized by the presence of a series of similar segments or **metameres**; segmentation.

metameter a quantity derived from an observation, and independent of all parameters, that conveys the magnitude of the phenomenon observed. A metameter is frequently used to simplify the expression or analysis of dose–response relationships.

metamorphosis 1 a complete change in physical form; a structural transformation. **2** (*in zoology*): the rapid, postembryonic, structural transformation from a larva into an adult that occurs in certain animals, e.g. the change from a tadpole to a frog. —**metamorphose** *vb.*; **metamorphic** *adj.*

metanephrine or **metadrenaline** 3-*O*-methylepinephrine; an inactive metabolite of epinephrine, produced by the action of **catechol *O*-methyltransferase**. Small quantities are normally found in the urine, and larger amounts occur in the urine of patients with catecholamine-secreting tumours.

metaphase the stage in **mitosis**, following **prometaphase**, during which the chromosomes become arranged so that their centromeres all lie in one plane and their longitudinal axes are at right angles to the spindle axis; the corresponding phases in **meiosis**.

metaphosphatase an alternative name for **1** endopolyphosphatase (EC 3.6.1.10). **2** exopolyphosphatase (EC 3.6.1.11).

metaphosphate the traditional name for any anion or any (partial or full) salt or ester derived from the condensed acid metaphosphoric acid, polytrioxophosphoric(V) acid, (HPO₃)_{*n*}, where *n* is a small integer, commonly 3, 4, or 6. Metaphosphoric acid and its derivatives are thought not to exist in the monomeric state, although they are often represented as such for convenience. *See also* polyphosphate.

metaprotein an old term for the products formed by acid or alkaline hydrolysis of proteins that are soluble in weak acids or alkalis but insoluble in neutral solutions.

metarhodopsin either of two intermediates, metarhodopsin I (absorption maximum 480 nm) and metarhodopsin II (absorption maximum 380 nm), formed during the photolysis of **rhodopsin**.

metastable 1 a describing any body or system existing in a state of apparent equilibrium when undisturbed, or subject to very small perturbation, but capable of passing to a more stable state when subjected to greater perturbation. **b** describing such a state or such an equilibrium. **2** describing an excited state of an atom, ion, nucleus, or other quantum-mechanical system that is relatively long-lived because the transitions to a lower energy state are forbidden transitions. **3** *symbol:* *m*; describing any comparatively stable excited state of a radioisotope that decays to a more stable state by isomeric transition, with the emission of gamma radiation, e.g. the metastable nuclide ^{99m}Tc, which is formed by decay of ^{99m}Mo and which in turn decays by transition to its nuclear isomer ⁹⁹Tc with a half-life of 6 h and emission of one quantum of gamma radiation.

metastasis (*pl.* **metastases**) the transfer of disease, especially tumour cells, from one part of the body to another by way of the natural passages (blood vessels, lymphatics) or by direct continuity. —**metastasize** or **metastasise** *vb.*; **metastatic** *adj.*

metazoa the plural of **metazoan** (def. 1) or **metazoan**.

Metazoa a subkingdom of animals consisting of multicellular animals whose cells are organized into tissues and their activities coordinated by a nervous system. The group includes all animals except the Protozoa and Parazoa.

metazoal a variant form of **metazoan** (def. 2).

metazoan 1 or **metazoan** (*pl.* **metazoa**) any animal of the subkingdom Metazoa. **2** or **metazoal** or **metazoic** of, characteristic of, or belonging to the Metazoa.

metazoic a variant form of **metazoan** (def. 2).

metazoön (*pl.* **metazoa**) an alternative term for **metazoan** (def. 1).

[Met⁵]enkephalin or **[Met]enkephalin** *abbr.* for [5-methionine]enkephalin.

meter 1 an instrument or device for measuring (and recording) the quantity of something (either instantaneously or cumulatively). **2** to measure (something) by means of a **meter** (def. 1). **3** to supply

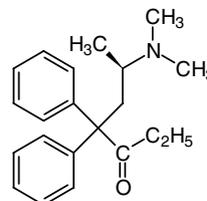

(something) in a measured or regulated amount. **4** *the US spelling of metre.*

+meter *comb. form* denoting an instrument or device for measuring (something indicated or specified). —**+metric** *adj.*

metestrus *see* **estrous cycle**.

meth- a variant form of **metho-** (*before a vowel*).

methadone (hydrochloride) 6-dimethylamino-4,4-diphenyl-3-heptanone hydrochloride; a narcotic analgesic used in cases of opioid dependence.

R-(-)-enantiomer

methaemoglobin a variant spelling (*esp. Brit.*) of **methemoglobin**.

methaemoglobinaemia a variant spelling (*esp. Brit.*) of **methemoglobinemia**.

methane or **marsh gas** a colourless, odourless, flammable gas, CH₄; it is the simplest alkane and is the principal constituent of natural gas found in association with mineral oil. It is formed by the anaerobic decay of vegetable matter and in large amounts by ruminants and other herbivores.

methano- *comb. form.* **1** indicating methane. **2** (*in chemical nomenclature*) denoting the presence of a –CH₂– bridge in a polycyclic hydrocarbon. **3** indicating organisms or compounds involved in metabolism of methane, e.g. **methanotroph**, **methanopterin**.

methanoate *see* **formate**.

methanogen any microorganism that produces methane. —**methanogenic** *adj.*

methanogenesis the microbial production of methane by anaerobic breakdown of carbon-containing compounds.

methanogenic the ability to form methane from CO₂, a property of some anaerobic bacteria. The pathway involves the coenzyme **tetrahydromethanopterin** (*abbr.:* H₄MPT), and involves formation of 5-formyl-H₄MPT, from which successively methenyl-H₄MPT, methylene-H₄MPT, and methyl-H₄MPT are formed in reactions analogous to those for **folate coenzymes**. From the last of these, methyl is transferred to **coenzyme M** to form methyl-coenzyme M, from which methane is formed in a reductive step involving **factor F₄₃₀**. *See also* **coenzyme F₄₂₀**.

methanol methyl alcohol; CH₃–OH; the lowest member of the alkanols. It is a colourless, flammable, mobile, poisonous liquid, widely used as a solvent. Numerous esters and ethers of methanol occur naturally, especially in plants. *Other names:* wood alcohol; wood spirit; carbinol. —**methanolic** *adj.*

methanol oxidase *see* **alcohol oxidase**.

methanolysis alcoholysis using methanol.

MethHb *abbr.* for methemoglobin (i.e. **ferrihemoglobin**).

methemalbumin or (*esp. Brit.*) **methaemalbumin** a complex of metheme with albumin, which imparts a brownish colouring to plasma. It is formed as the result of *in vitro* hemolysis.

methemoglobin or (*esp. Brit.*) **methaemoglobin** *abbr.:* MetHb; an older name for **ferrihemoglobin**.

methemoglobinemia or (*esp. Brit.*) **methaemoglobinaemia** any clinical condition characterized by an excess of **ferrihemoglobin** (i.e. methemoglobin) in the erythrocytes. It accompanies a number of **hemoglobinopathies**, and also results from administration of large amounts of sulfonamides. A hereditary enzymopenic methemoglobinemia is caused by mutations in the gene for cytochrome *b*₅ reductase. Ferrihemoglobin imparts a brown colour to urine.

methene an old name, still commonly used in biochemistry, for the trivalent diatomic group, =CH–, attached to two other groups in an organic molecule. The name now recommended is **methyne**.

methene bridge the **methene** group that links consecutive pyrrole rings in the molecular structure of tetrapyrroles and related compounds.

methenyl+ *prefix (to a trivial biochemical name)* denoting substitution of a **methene** group into the indicated parent compound (at the positions specified by appropriate locants); e.g. 5,10-methenyltetrahydrofolate. *Compare* **methylene+**.

methenyltetrahydrofolate cyclohydrolase EC 3.5.4.9; *systematic name*: 5,10-methenyltetrahydrofolate 5-hydrolase (decyclizing); one of the enzymes involved in transformations between **folate coenzymes**. It catalyses the hydrolysis of 5,10-methenyltetrahydrofolate to form 10-formyltetrahydrofolate. One of three enzymes (*see also* **methylenetetrahydrofolate dehydrogenase (NADP⁺)** and **formate-tetrahydrofolate ligase**) necessary for the biosynthesis of purines, thymidylate, methionine, histidine, pantothenate, and formyl tRNA-Met.

5,10-methenyltetrahydrofolate synthetase *see* **5-formyltetrahydrofolate cyclo-ligase**.

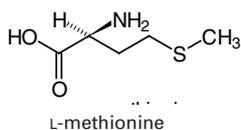

MeTHFA *abbr. for* 5-methyltetrahydrofolate.

methicillin *see* **meticcillin (sodium)**.

methine a former name for **methyne**.

methioninate **1** methionine anion; the anion, CH₃-S-[CH₂]₂-CH(NH₂)-COO⁻, derived from **methionine**. **2** any salt containing methionine anion. **3** any ester of methionine.

methionine *the trivial name for* α -amino- γ -methylmercaptobutyric acid; 2-amino-4-(methylthio)butanoic acid; CH₃-S-[CH₂]₂-CH(NH₂)-COOH; a chiral α -amino acid. L-Methionine (*symbol*: M or Met), (*S*)-2-amino-4-(methylthio)butanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: AUG (or also AUA in various species of mitochondria). D-Methionine (*symbol*: D-Met or DMet) is not known to occur naturally. In mammals, methionine is glucogenic, and is an essential dietary amino acid, although either enantiomer will serve (the D-form being oxidatively deaminated to the α -oxo acid, which is then reaminated with inversion).

methionine adenosyltransferase *abbr.* MAT; EC 2.5.1.6; *other names*: S-adenosylmethionine synthetase; AdoMet synthetase; an enzyme that catalyses the reactions:

Three isozymes (MATI-III) are formed by the two genes whose products are $\alpha 1$ (395 amino acids) and $\alpha 2$ (394 amino acids), which share 84% sequence identity. MATI is ($\alpha 1$)₄, while MATIII is ($\alpha 1$)₂, both being present in adult liver. MATII is present in many tissues and in fetal (but not adult) liver. Mutations in the $\alpha 1$ gene lead to isolated hypermethioninemia.

methionine cycle *see* **methionine salvage pathway**.

methionine dioxide *symbol*: MetO₂; methionine S,S-dioxide; CH₃-SO₂-[CH₂]₂-CH(NH₂)-COOH; an oxidation product of methionine, *formerly known (incorrectly) as* **methionine sulfone**.

[5-methionine]enkephalin *abbr.*: [Met]enkephalin or [Met⁵]enkephalin; the recommended designation for the trivial name of the pentapeptide Tyr-Gly-Gly-Phe-Met. *See* **enkephalin**.

methionine oxide *symbol*: MetO; methionine S-oxide; CH₃-SO-[CH₂]₂-CH(NH₂)-COOH; an oxidation product of methionine and an intermediate in the formation of **methionine dioxide**. *It was formerly known (incorrectly) as* **methionine sulfoxide**.

methionine salvage pathway or **methionine cycle** or **Yang cycle** a metabolic cycle occurring in plant cells in which methionine is synthesized from carbons originating in the ribose of ATP, the sulfur atom being conserved throughout the cycle. In outline, the cycle

consists of reactions in which, starting with L-methionine, **S-adenosylmethionine** (I) is formed in a reaction with ATP. I is then converted by L-aminocyclopropane-1-carboxylate synthase, EC 4.4.1.14, to 5'-methylthioadenosine (II) and L-aminocyclopropane-1-carboxylate, a precursor of ethylene (*see* **ethylene-forming enzyme**). 5'-Methylthioadenosine is also produced during synthesis of polyamines. Adenine is then cleaved from methylthioadenosine to form 5-methylthioribose from which 5-methylthioribose-1-phosphate (III) is formed by reaction with ATP. III is then converted through a series of intermediates to 2-keto-4-methylthiobutyrate from which methionine is formed by a transamination reaction. [After S.F. Yang.]

methionine sulfone an old (*incorrect*) name for **methionine dioxide**.

methionine sulfoxide an old (*incorrect*) name for **methionine oxide**.

methionine sulfoximine [3-amino-3-carboxypropyl]methyl sulfoximine; an inhibitor of glutamine synthetase (**glutamate-ammonia ligase**) in plants, and identified as the toxic agent in flour treated with the bleaching agent NCl₃ (agene, hence the term **agenized flour**). It interferes with the action of γ -amino-*n*-butyric acid in the brain. This is associated with the ability of methionine sulfoximine to cause fits in a wide variety of animals – ferrets are particularly susceptible. Although methionine sulfoximine has not been clearly proven to be toxic to humans, agene is no longer used for bleaching flour.

methionine synthase *see* **homocysteine methyltransferase**.

methioninium methionine cation; the cation, CH₃-S-[CH₂]₂-CH(NH₃⁺)-COOH, derived from **methionine**.

methionino the alkylamino group, CH₃-S-[CH₂]₂-CH(COOH)-NH-, derived from **methionine**.

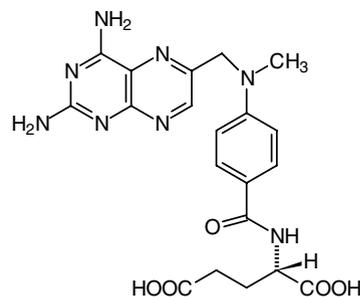

methionyl the acyl group, CH₃-S-[CH₂]₂-CH(NH₂)-CO-, derived from **methionine**.

methionyllysylbradykinin or **Met-Lys-bradykinin** *see* **bradykinin**.

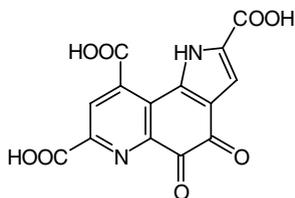

methionyl-tRNA formyltransferase EC 2.1.2.9; *systematic name*: 10-formyltetrahydrofolate:L-methionyl-tRNA *N*-formyltransferase. An enzyme that catalyses a reaction between 10-formyltetrahydrofolate, L-methionyl-tRNA, and H₂O to form tetrahydrofolate and *N*-formylmethionyl-tRNA. *N*-formylmethionyl-tRNA is involved in the initiation of prokaryote translation.

metho+ or (*before a vowel*) **meth+** (*comb. form*) a variant of **methyl+** in the names of certain chemical compounds.

methotrexate 4-amino-10-methylfolic acid; *other name*: amethopterin; a folic acid analogue that is a potent competitive inhibitor (*K_i* < 10⁻⁹ M) of **dihydrofolate reductase**. It is useful in the treatment of acute leukemia and choriocarcinoma. It acts by blocking nucleotide synthesis and thus also DNA synthesis and has similar activity to **aminopterin**. The crystal structure of a complex of methotrexate and dihydrofolate reductase from *Lactobacillus casei* is known.

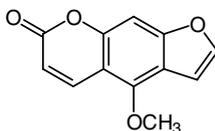

methoxatin or **pyrroloquinoline quinone** 4,5-dihydro-4,5-dioxo-1H-pyrrolo-[2,3-*f*]quinoline-2,7,9-tricarboxylic acid; a heat-stable fluorescent cofactor implicated in the action of primary alcohol dehydrogenases in methylotrophic bacteria and possibly more generally associated with the oxidation of single-carbon compounds. *See* **quinoprotein**.

methoxy *symbol*: OMe or MeO; the alkoxy group, $\text{CH}_3\text{-O-}$, derived from methanol by loss of a hydrogen atom.

3-methoxy-4-hydroxymandelate acid *see* hydroxymethoxymandelate.

5-methoxypsoralen an intercalating reagent for DNA; it forms covalent cross-links on irradiation. *See also* psoralen.

methoxyvinylglycine *abbr.*: MVG; L-2-amino-4-methoxy-*trans*-3-butenic acid; an inhibitor of ethylene biosynthesis in plants.

methuselah a gene of *Drosophila* for a long N-terminal type B G-protein-coupled membrane receptor that regulates the ageing process. Its reduced expression increases resistance to various types of stress (e.g. starvation, high temperature, dietary toxins) and increases lifespan by 35%, but null mutations are lethal to embryos.

methyl *symbol*: Me; the alkyl group, $\text{CH}_3\text{-}$, derived from methane.

methyl- *prefix (in chemical nomenclature)* used as a locant to indicate in or at a methyl group.

methyl-accepting chemotaxis protein *abbr.*: MCP; any of several similar integral plasma membrane proteins that may be present in the cell membranes of particular strains of certain motile bacteria, e.g. *Escherichia coli* and *Salmonella typhimurium*, and appear to mediate their responses to corresponding classes of chemotactic agent by undergoing enzymic methylation/demethylation of the γ -carboxylate group(s) of one or more glutamic residues (for the enzymes responsible *see che*). The type of ligand determines the reaction, which in turn determines the action of the receptor on the bacterial flagellar motor, so that the effect can be either attractant or repellent. The following examples are from *E. coli*. MCP1 is a receptor for attractants such as L-serine and other amino acids and is also responsible for avoidance of a wide range of repellents, including leucine, indole, and weak acids. MCP2 is a receptor for L-aspartate, dicarboxylic acids, and maltose (via interaction with a periplasmic maltose-binding protein), and is also responsible for avoidance of cobalt and nickel. MCP3 interacts with periplasmic ribose- or galactose-binding proteins and mediates movement towards these sugars. MCP4 interacts with periplasmic dipeptide-binding proteins and mediates movement towards such peptides.

N^6 -methyladenine a methylated base of DNA; this and **5-methylcytosine** are the only modified bases in the DNA of cellular organisms.

methyl alcohol a common name for methanol.

methylase a common name for methyltransferase.

methylaspartase *see* methylaspartate mutase.

***N*-methyl-D-aspartate** *abbr.*: NMDA; an excitatory amino acid and a neurotransmitter. It acts as agonist for the *N*-methyl-D-aspartate receptor, a subclass of glutamate ionotropic receptors (*see* glutamate receptor).

methylaspartate ammonia-lyase *recommended name* for methylaspartase; *see* methylaspartate mutase.

methylaspartate mutase EC 5.4.99.1; *systematic name*: L-threo-3-methylaspartate carboxy-aminomethylmutase; *other name*: glutamate mutase. An enzyme that catalyses the reaction:

This is the first step of the glutamate-fermentation pathway of the anaerobic bacteria *Clostridium cochlearium*, *C. tetanomorphum*, and others. The product, (2*S*,3*S*)-3-methylaspartate, is converted to mesaconate by the enzyme methylaspartate ammonia-lyase (EC 4.3.1.2). Methylaspartate mutase requires a cobamide coenzyme and has been studied as an example of such a reaction. The enzyme has two subunits (large and small, sometimes called E and S).

methylate 1 to introduce (one or more) methyl groups into (a substance). **2** (*in commerce*) to mix or adulterate with methanol. *See also* methylation of DNA. —**methylation** *n*.

methylated-DNA-protein-cysteine S-methyltransferase EC 2.1.1.63; *other names*: 6-*O*-methylguanine-DNA methyltransferase; O^6 -methylguanine-DNA-alkyltransferase. It catalyses the reaction between DNA (containing 6-*O*-methylguanine) and protein L-cysteine to form DNA (without 6-*O*-methylguanine) and protein S-methyl-L-cysteine. As the acceptor is in the enzyme itself this is a 'suicidal' reaction. Bacterial and mammalian enzymes have common motifs.

methylation of DNA the occurrence in vertebrate DNA of varying amounts of 5-methylcytosine which arises from methylation of cytosine bases where they occur in the sequence CpG. The methylation status of DNA correlates with its functional activity: inactive genes are more heavily methylated. *See also* CpG islands.

3-methylcholanthrene a carcinogenic hydrocarbon, found in coal tar. It induces synthesis of cytochrome P450 mRNA.

methyl-coenzyme M reductase EC 2.8.4.1; coenzyme-B sulfoethylthiotransferase; a nickel-containing enzyme that catalyses the methane-releasing reaction in methanogenic bacteria. Severe enzyme deficiency from many mutations leads to developmental delay, seizures, and psychiatric manifestations, hyperhomocystinemia and homocystinuria, premature atherosclerosis, and demyelination. *See* factor F_{430} .

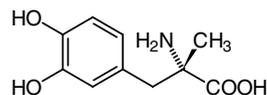

methyl CoM reductase coenzyme-B sulfoethylthiotransferase, EC 2.8.4.1, an enzyme in methanogenic archaea that catalyses the final reaction of methanogenesis: the reaction of methyl coenzyme M and coenzyme B, with the formation of the mixed disulfide and release of methane. Contains the nickel-containing factor F_{430} .

methylCpG-binding protein 2 *abbr.*: MECP2; a ubiquitously expressed, very abundant nuclear protein (486 amino acids) of human tissues that is associated with 5-methylcytosine-rich heterochromatin. It helps recruit histone deacetylases and other proteins. Mutations result in an X-chromosome-linked neurodegenerative disorder of girls that starts 6–18 months after birth and is called Rett syndrome.

methylcrotonyl-CoA carboxylase EC 6.4.1.4; an enzyme of the pathway for the degradation of leucine. It catalyses the formation of 3-methylglutaconyl-CoA from ATP, 3-methylcrotonyl-CoA, and HCO_3^- with release of ADP and orthophosphate. Biotin is a cofactor. The 3-methylglutaconyl-CoA is then converted to 3-hydroxy-3-methylglutaryl-CoA.

5-methylcytosine a methylated base of DNA; this and **N^6 -methyladenine** are the only modified bases in the DNA of cellular organisms. In T-even phages all the C residues of DNA are 5-hydroxymethylcytosine.

methyl dopa L-2-amino-2-methyl-3-(3,4-dihydroxyphenyl)propionic acid; a compound used as an antihypertensive. It is a competitive inhibitor of aromatic L-amino acid decarboxylase (dopa decarboxylase), but its effects on blood pressure may result from its metabolism to α -methylnorepinephrine, which stimulates presynaptic α_2 receptors, thus decreasing norepinephrine release.

methylene 1 the recommended name for the bivalent triatomic group CH_2 in a molecule, whether attached to two other atoms by single bonds or to one other atom by a double bond. **2** a former name for carbene (def. 1).

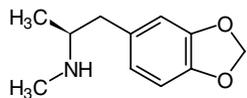

methylene+

methylene+ *prefix (to a trivial chemical name)* denoting substitution of a **methylene** group into the indicated parent compound (at the positions specified by appropriate locants); e.g. 5,10-methylenetetrahydrofolate (which may be shortened to 5,10-CH₂-H₄folate). Compare **methenyl+**.

N,N'-methylenebisacrylamide (CH₂:CHCONH₂)₂CH₂; a cross-linking agent used in a ratio (w/w) of between 1:49 and 1:19 with acrylamide in the preparation of polyacrylamide gels.

Methylene Blue or **Swiss Blue** or **Basic Blue 9** CI 52015; tetramethylthionine chloride; 3,7-bis(dimethylamino)phenothiazinium chloride; a water- and ethanol-soluble blue dye; A_{\max} (in water) at 663–667 nm. It is reducible to a leuco (i.e. colourless) compound, which is reoxidizable by dioxigen, and hence is useful as a redox indicator; E° (pH 7.0, 30°C) = +0.011 V. It is useful also as a stain in bacteriology and histology, e.g. being preferentially taken up by melanin-containing cells, and can be used to target therapeutic agents to such cells.

3,4-methylenedioxymethamphetamine *abbr.*: MDMA; a phenethylamine derivative and analogue of **mescaline** and **amphetamine** that is a potent CNS stimulant and hallucinogen; *popularly known as ecstasy*. A controlled substance in the US Code of Federal Regulations.

S-(+)-enantiomer

2-methyleneglutarate mutase EC 5.4.99.4; *systematic name*: 2-methyleneglutarate carboxy-methylenemethylmutase. An enzyme that catalyses the reaction:

It is a key enzyme in the fermentation of nicotinate to ammonia, propionate, acetate, and CO₂ by the strict anaerobe *Clostridium barkeri*, but has been much investigated as an example of an enzyme mechanism based on the adenosylcobalamin coenzyme. 2-Methylene-3-methylsuccinate is converted to 2,3-dimethylmaleate by methylitaconate Δ -isomerase (EC 5.3.3.6). The enzyme is a homotetramer of 70 kDa subunits.

methylene-interrupted double bonds double bonds separated by one methylene group. The term is used especially to describe the double bonds in naturally occurring long-chain fatty acids; in many cases these are all of the *Z* configuration, with each pair separated by one methylene group.

methylenetetrahydrofolate dehydrogenase (NADP⁺) EC 1.5.1.5; *systematic name*: 5,10-methylenetetrahydrofolate: NADP⁺ oxidoreductase. *other name*: CI-tetrahydrofolate synthase, cytosolic; an enzyme involved in the interconversion of folate coenzymes that catalyses the reaction:

One of three enzymes (*see also* **methenyltetrahydrofolate cyclohydrolase**, and **formate-tetrahydrofolate ligase**) necessary for the biosynthesis of purines, thymidylate, methionine, histidine, pantothenate, and formyl tRNA-Met. The human enzyme is a cytosolic trifunctional homodimer of 934 amino acids; the N-terminal domain (amino acids 1–304) has methylenetetrahydrofolate dehydrogenase and cyclohydrolase activity; the C-terminal section (305–934) forms the formyltetrahydrofolate synthetase domain (*other names*: mitochondrial (precursor) NAD-dependent methylenetetrahydrofolate dehydrogenase (EC 1.5.1.5); methenyltetrahydrofolate cyclohydrolase (EC 3.5.4.9)).

methyltransferase any of various enzymes that catalyse the hydrolysis of methyl esters. For example, **juvenile-hormone esterase** (EC 3.1.1.59) of insects, *other name*: JH-esterase, catalyses the hydrolysis of methyl (2*E*,6*E*)-(10*R*,11*S*)-10,11-epoxy-3,7,11-trimethyltrideca-2,6-dienoate to form (2*E*,6*E*)-(10*R*,11*S*)-10,11-epoxy-

2-methyl-1,4-naphthalenedione

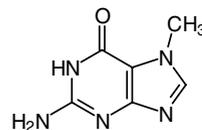

3,7,11-trimethyltrideca-2,6-dienoate and methanol; i.e. it demethylates the insect juvenile hormones JH₁ and JH₂. It is similar to certain other carboxylesterases and lipases. The **protein-glutamate methyltransferase** of *Escherichia coli* is involved in chemotaxis in this organism (*see che*).

methylglucosamine *N*-methyl-L-glucosamine; 2-deoxy-2-(methylamino)-L-glucose; a component of **streptomycin**.

3-methylglutaconic aciduria any condition in which there is excess 3-methylglutaconic acid in urine. Type I is due to deficiency of a specific hydratase that converts 3-methylglutaconyl-CoA to 3-hydroxy-3-methylglutaryl-CoA in mitochondria during catabolism of leucine. Type II (*see* **Barth syndrome**) is due to mutations in **tafazzin**, and like types III and IV is associated with normal 3-methylglutaconyl-CoA hydratase activity.

O⁶-methylguanine a modified and, in principle, highly mutagenic base in DNA (it base pairs with T). It has a special repair enzyme, **methylated-DNA-protein-cysteine S-methyltransferase**.

7-methylguanine a modified base found in transfer RNA. *See* **guanine** (for numbering), **7-methylguanosine**.

7-methylguanosine a modified nucleoside that forms a **cap** at the 5'-terminus of eukaryotic mRNA. *See also* **7-methylguanine**.

methylidyne *the recommended name* for the trivalent diatomic group CH≡ attached to a single other group in a molecule of an organic compound. Compare **methine**.

methylmalonate CH₃CH(COO⁻)₂; isosuccinate 2-methylpropanedioate; the dianion of methylmalonic acid; as **methylmalonyl-CoA** it is an intermediate in the conversion of propionyl-CoA to succinyl-CoA. Note: methylmalonate should be distinguished from methylmalonate (two words), which is propanedioic acid dimethyl ester.

methylmalonic acidemia or **methylmalonic aciduria** any autosomal recessive disease in which abnormally large amounts of methylmalonate occur in the blood and urine. The condition may be caused by abnormalities in either **methylmalonyl-CoA epimerase** or **methylmalonyl-CoA mutase** apoenzymes, or by three different abnormalities in adenosylcobalamin synthesis.

methylmalonyl-CoA 2-carboxypropanoyl-CoA; it can exist as the enantiomers (*R*)- and (*S*)-methylmalonyl-CoA; (*S*)-methylmalonyl-CoA is an intermediate in the **beta oxidation** of odd-numbered fatty acids in animals. Propionyl-CoA is the major end product; for further metabolism, this is converted to succinyl-CoA by, first, carboxylation to (*S*)-methylmalonyl-CoA, which is converted by **methylmalonyl-CoA epimerase** to (*R*)-methylmalonyl-CoA, which is then converted to succinyl-CoA by **methylmalonyl-CoA mutase**.

methylmalonyl-CoA epimerase EC 5.1.99.1; an enzyme that interconverts (*R*)-methylmalonyl-CoA to (*S*)-methylmalonyl-CoA. It is sometimes incorrectly referred to as methylmalonyl-CoA racemase (chiral centres in the CoA moiety are not affected).

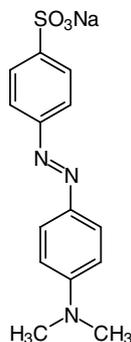

methylmalonyl-CoA mutase EC 5.4.99.2; *systematic name*: (*R*)-2-methyl-3-oxopropanoyl-CoA CoA-carbonylmethylmutase; an enzyme that converts (*R*)-methylmalonyl-CoA to succinyl-CoA; adenosylcobalamin is a cofactor. This mitochondrial matrix enzyme is required for degradation of several amino acids, odd-chain fatty acids, and cholesterol via propionyl-CoA to the tricarboxylic-acid cycle; deficiency results in **methylmalonic acidemia**. In some bacteria the enzyme is a heterodimer; both subunits have homology with the human protein. Its role is in the synthesis of propionate from tricarboxylic-acid-cycle intermediates.

methylmercuric hydroxide a powerful reagent used for the denaturation of the secondary structure of RNA molecules, but limited in its use owing to its toxicity.

2-methyl-1,4-naphthalenedione 2-methyl-1,4-naphthoquinone; *see* **menadione**.

Methyl Orange

Methyl Orange a dye used as an indicator, changing from red to orange-yellow over the pH range 3.1–4.4.

methylotroph any organism that can use certain single-carbon compounds, in a lower oxidation state than CO₂, as sole carbon source. —**methylotrophic** *adj.*; **methylotrophy** *n.*

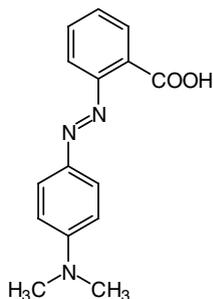

methylotrophic yeast any yeast belonging to either of the genera *Hansenula* or *Pichia*. They are potentially valuable recombinant-DNA expression hosts as certain oxidase genes (*MOX* and *AOX*) are vastly overexpressed and their promoters are suitable for the expression of foreign proteins. See also **alcohol oxidase**, **methylotroph**.

3-methyl-2-oxobutanoate dehydrogenase (lipoamide) EC 1.2.4.4; *other names*: 2-oxoisovalerate dehydrogenase; branched-chain α -keto-acid dehydrogenase; branched-chain α -keto-acid decarboxylase; an enzyme present in a complex that catalyses the oxidative decarboxylation of oxo acids derived from branched-chain amino acids. It is similar in mechanism to the **pyruvate dehydrogenase complex**. The E₁ component of the complex, it catalyses the release of CO₂ from the oxo acid and transfer of the resulting acyl group to lipoamide. Thus, for the oxo acid from valine, it catalyses the reaction of 3-methyl-2-oxobutanoate with lipoamide to form *S*-(2-methylpropanoyl) dihydrolipoamide with release of CO₂. Thiamine diphosphate is a coenzyme. See also **[3-methyl-2-oxobutanoate dehydrogenase (lipoamide)] kinase**.

[3-methyl-2-oxobutanoate dehydrogenase (lipoamide)] kinase EC 2.7.1.115; *other name*: branched-chain α -keto-acid dehydrogenase kinase; an enzyme that catalyses the phosphorylation by ATP of [3-methyl-2-oxobutanoate dehydrogenase (lipoamide)] with release of ADP, thereby inactivating the enzyme complex.

[3-methyl-2-oxobutanoate dehydrogenase (lipoamide)]-phosphatase EC 3.1.3.52; *other name*: branched-chain oxo-acid dehydrogenase phosphatase; an enzyme that catalyses the hydrolysis of phosphate from [3-methyl-2-oxobutanoate dehydrogenase (lipoamide)] phosphate.

Methyl Red a dye used as an indicator, changing from red to yellow over the pH range 4.2–6.3.

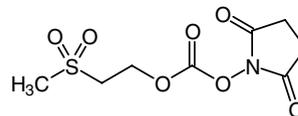

methylsulfonyl nitrophenyl carbonate 2-(methylsulfonyl)ethyl 4-nitrophenyl carbonate; a reagent used for the introduction of the **MSOC** amino-protecting group.

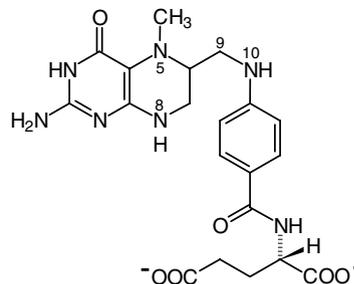

methylsulfonyl succinimidyl carbonate 2-(methylsulfonyl)-

meticillin (sodium)

ethyl *N*-succinimidyl carbonate; a reagent used for the introduction of the **MSOC** amino-protecting group.

5-methyltetrahydrofolate *abbr.*: MeTHFA or 5-CH₃-H₄folate; a member of the tetrahydrofolate group of coenzymes. It is an intermediate in the methylation of vitamin B₁₂, which can then react with homocysteine to form methionine. The methyl group of MeTHFA is derived from C-3 of serine via 5,10-methylene H₄folate.

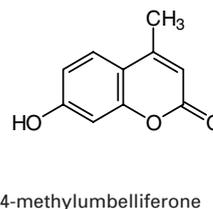

methyltetrahydrofolate trap hypothesis a hypothesis to explain the accumulation of 5-methyltetrahydrofolate (5-CH₃-H₄folate) in the sera of patients with vitamin B₁₂ deficiency. It suggests that, because the only route by which 5-CH₃-H₄folate can be converted to H₄folate (required for single-carbon transfer reactions) is by the vitamin B₁₂-dependent 5-methyltetrahydrofolate-homocysteine *S*-methyltransferase (EC 2.1.1.13) reaction, a large proportion of the body's available folate becomes trapped as 5-CH₃-H₄folate, leading to folate deprivation.

methylthioribose 5-methylthio-D-ribose; an intermediate in the **methionine salvage pathway**.

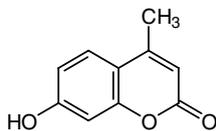

methyltransferase any enzyme of sub-subclass EC 2.1.1, members of which catalyse the transfer of a methyl group. See also **che**, **θ -methylguanine**.

4-methylumbelliferyl *abbr.*: MU; a group that is attached in glycosidic linkage to various sugars to form substrates useful in the assay of glycosidases. The highly fluorescent 4-methylumbelliferone is released on enzyme action, and can be measured in alkaline solution by its fluorescence (max. 448 nm, excitation at 364 nm), which is quenched in the glycosidic substrate. See also **MUG**.

methyne or (formerly) **methine** the name now recommended for the trivalent diatomic group, =CH-, attached to two other groups in an organic molecule. Such a group is commonly still known in biochemistry as **methene**. Compare **methylidyne**.

meticillin (sodium) or **methicillin** a semisynthetic antibiotic of the **penicillin** type that is lactamase resistant.

metJ the gene for the repressor (co-repressor is *S*-adenosylmethionine) of the methionine biosynthetic operon, and also *metJ* itself, in *Escherichia coli*. The repressor protein undergoes dimeric binding to DNA by a motif other than a helix-turn-helix.

Met-Lys-bradykinin a short name for methionyllysylbradykinin; see **bradykinin**.

MetMb *abbr.* for metmyoglobin (i.e. **ferrimyoglobin**).

metmyoglobin *abbr.*: MetMb; an old name for **ferrimyoglobin**.

'me too drug' a drug that uses the same therapeutic mechanism as an existing drug, offering no significant additional benefit. Notwithstanding the negative connotations of the term 'me too', such products compete directly with those currently on the market, and hence may help to push prices down.

metre or (US) **meter** *symbol*: m; the SI base unit of length, equal to the length of the path travelled by light in a vacuum during a time interval of $1/299\,792\,458$ of a second.

metre-kilogram-second system (of electrical units) *abbr.*: mks system or MKS system; a system of electrical (physical) units based on the metre, kilogram, and second as fundamental units of measurement. It has now been superseded by the SI system of units.

metric 1 of, or relating to, the metre or the metric system. **2** quantitative.

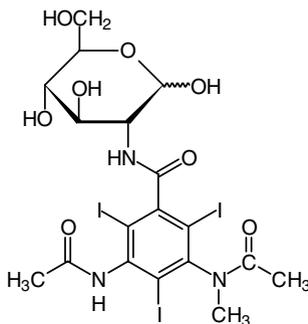

+metric see **+meter**, **+metry**.

metric system a system of weights and measures, devised in France (1793–95), based on the principle that each of the physical quantities length, volume, and mass should be defined in terms of one unit whose multiples and submultiples are related by powers of ten and that all three units should be simply interrelated. The units were, respectively, the metre, the litre (one cubic decimetre), and the gram (the mass of one cubic centimetre of water at its maximum density). It has now been supplanted by the International System of Units (see **SI**).

metridin 1 a 36-amino acid, 3.97 kDa toxin from *Metridium senile* (brown sea anemone). **2** or **metridium proteinase A** EC 3.4.21.3; *other name*: sea anemone protease A; an enzyme that catalyses the preferential cleavage: Tyr-|-Xaa > Phe-|-Xaa > Leu-|-Xaa; it has little action on Trp-|-Xaa.

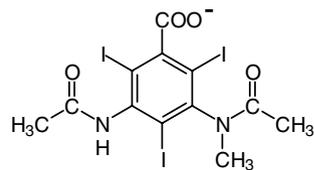

metridium proteinase A see **metridin** (def. 2).

metrizamide the trivial name for 2-[3-acetamido-5-(*N*-methylacetamido)-2,4,6-triiodobenzamido]-2-deoxy-D-glucose; a dense, synthetic, nonionic substance, highly soluble in water, that is capable of forming (nonautoclavable) aqueous solutions of densities up to 1.3 g cm^{-3} , useful as media for **isopycnic centrifugation** of biological particles.

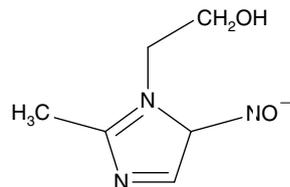

metrizoate the trivial name for the 3-acetamido-5-(*N*-methylacetamido)-2,4,6-triiodobenzoate anion; a dense, synthetic substance

used primarily as its sodium salt, which is highly soluble in water and capable of forming autoclavable aqueous solutions of densities up to 1.4 g cm^{-3} , or more, such solutions being useful as media for **isopycnic centrifugation** of biological particles.

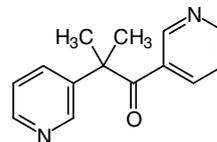

metronidazole 2-methyl-5-nitroimidazole-1-ethanol; an antibiotic used to treat a variety of bacterial and parasitic infections, such as amebiasis, trichomoniasis, and giardiasis. It is a prodrug, which is converted by reduction to a cytotoxic radical.

metronidazole radical

+metry *comb. form* denoting the process or science of measuring (something indicated or specified). —**+metric** *adj.*

metryrapone 2-methyl-1,2-di(3-pyridyl)propan-1-one; an inhibitor of the enzyme 11β -hydroxylase (steroid 11β -monooxygenase; EC 1.14.15.4); this enzyme is involved in the synthesis of cortisone, cortisol and aldosterone, its inhibition causing a rise in **corticotropin** secretion as a result of release from negative feedback on the pituitary by cortisol. Metyrapone is used in **challenge** tests of hypothalamic-pituitary function and sometimes in the treatment of **Cushing's syndrome**.

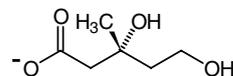

MeV *symbol* for mega-electronvolt (i.e. 10^6 electronvolts).

Mevacor a proprietary name for **lovastatin**.

mevaldate 1 the anion $\text{OHC-CH}_2\text{-C}(\text{CH}_3)(\text{OH})\text{-CH}_2\text{-COO}^-$ derived from mevaldic acid; its (*R*)-enantiomer occurs as an enzyme-bound intermediate during the conversion of hydroxymethylglutaryl-coenzyme A to mevalonate in the biosynthesis of polyprenyl compounds. **2** any salt or ester of mevaldic acid.

mevalonate 1 the anion, $\text{HO-}[\text{CH}_2]_2\text{-C}(\text{CH}_3)(\text{OH})\text{-CH}_2\text{-COO}^-$, derived from mevalonic acid; its (*R*)-enantiomer is a strategic intermediate derived from hydroxymethylglutaryl-CoA in the biosynthesis of polyprenyl compounds. **2** any salt or ester of mevalonic acid.

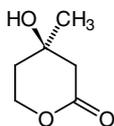

(*R*)-mevalonate

mevalonate kinase a hepatic peroxisomal enzyme (396 and 395 amino acids in human and rat, respectively) that phosphorylates mevalonate to form mevalonic acid-5-phosphate in the metabolic pathway that leads to cholesterol and other isoprenoid compounds. Severe deficiency of the enzyme leads to **mevalonic aciduria**. Less severe deficiency (5–15% of normal activity) leads to **hyper-IgD syndrome**.

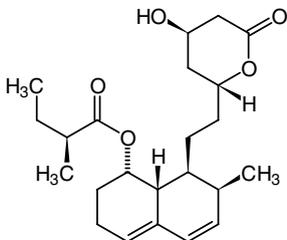

mevalonic aciduria a rare, severe, autosomal recessive disease with increased plasma levels of mevalonate and pronounced mevalonic aciduria, and characterized by dysmorphic features, hepatosplenomegaly, and severe developmental delay. It is caused by several mutations in the gene at 12q24 for **mevalonate kinase** that lead to severe deficiency of this enzyme. *Compare* **hyper-IgD syndrome**.

mevalonolactone mevalonic acid lactone; it is hydrolysed in cells to mevalonate, and is often the form in which mevalonate is administered to animals or cells, either radioactively or non-radioactively as a metabolic precursor.

mevalonyl the acyl group, HO-[CH₂]₂-C(CH₃)(OH)-CH₂-CO-, derived from mevalonic acid.

mevastatin or **compactin** 6-demethylmevinolin; a substance isolated from *Penicillium citrinum*; it is a potent inhibitor of **HMG-CoA reductase** with actions similar to **lovastatin**.

Mevinacor a proprietary name for **lovastatin**.

mevinolin an alternative name for **lovastatin**.

Meyerhof pathway *see* **Emden–Meyerhof pathway**.

Meyerhof quotient an index of the effect of the presence or absence of dioxygen on glycolysis or fermentation. It is: [(rate of anaerobic fermentation) – (rate of aerobic fermentation)]/(rate of dioxygen uptake). Assuming 6 mol ATP are formed per mol dioxygen used, a Meyerhof quotient of 6 would mean that aerobic and anaerobic energy supply are the same; a lower value indicates an increase in ATP-supplying and ATP-requiring processes on transition from anaerobic to aerobic conditions. [After Otto Fritz Meyerhof (1884–1951), German physiologist and biochemist.]

mfd *abbr.* for microfarad.

MflI a type 2 **restriction endonuclease**; recognition sequence: [AG]↑GATC[TC]. *XhoII* is an **isoschizomer**.

mg *symbol* for milligram (i.e. 10⁻³ gram).

Mg *symbol* for magnesium.

Mgm1 a yeast dynamin-like protein that forms a ring on the outer surface of the inner mitochondrial membrane to bring about fission of the organelle. Homologues occur in animals and plants.

MHC *abbr.* for major histocompatibility complex.

MHC class II deficiency the deficiency or absence of MHC class II antigens on lymphocytes and macrophages, which leads to abnormal susceptibility of humans to infections. It results from mutations in any component of the heterotrimeric **RFX** complex, which

binds a part of the response element in the promoter region of MHC class II genes. *See* **major histocompatibility complex**.

mho a practical unit of electric conductance equal to the reciprocal of the impedance measured in ohms. For circuits containing only noninductive resistance the **siemens** is the preferred unit.

MHS *abbr.* for major histocompatibility system (i.e. **major histocompatibility complex**).

MIC *abbr.* for minimum inhibitory concentration.

mica substrate technique a technique used in preparing specimens of macromolecules for electron microscopic examination. Freshly cleaved mica is used to support the specimen during shadowing with a metal; a backing film of carbon is then applied by evaporation normal to the shadowed surface, and both films are transferred to the grid.

micelle 1 an aggregate, of colloidal dimensions, of oriented molecules of amphipathic substances existing in equilibrium in solution with the chemical species from which it is formed; micelles are generally electrically charged. In aqueous solution the individual molecules of the micellar aggregate are oriented with their polar groups pointing towards the aqueous medium and their hydrophobic moiety directed into the centre of the micelle. **2** a hypothetical ordered region in a natural fibre such as cellulose. —**micellar** *adj.*

micellization or **micellisation** transformation into micelles.

micF a regulatory gene in the osmoregulatory system in *Escherichia coli*; *micF* RNA and *ompF* mRNA (*omp* = outer membrane protein) are induced by interaction of *ompR* with a common divergent, central promoter region. *micF* RNA is partly complementary to the Shine–Dalgarno region of *ompC* and thus represses its expression by translational control.

Michaelian of, relating to, or described by **Michaelis kinetics**.

Michaelis kinetics or **Michaelis–Menten kinetics** or **Henri–Michaelis–Menten kinetics** a model to explain the kinetics of an enzyme-catalysed reaction,

where E is enzyme, S is substrate, ES is an intermediate complex (the **Michaelis complex**), and P is product. The initial velocity of the reaction, *v*, when [P] = 0, is given by the **Michaelis equation** (or **Michaelis–Menten equation** or **Henri–Michaelis–Menten equation**):

$$v = V[S]/(K_m + [S]) = d[P]/dt$$

in which *V* is the limiting or maximal reaction rate (i.e. that occurring when the enzyme is saturated with substrate), and the **Michaelis constant**, *K_m*, is given by:

$$K_m = (k_{-1} + k_{cat})/k_{+1}$$

If *k_{cat}* << *k₊₁*, then *K_m* approximates to *K_s*, the enzyme–substrate dissociation constant (usually known as the **substrate dissociation constant**). *K_m* and *V* are known as the **Michaelis parameters**. *Compare* **Dalziel coefficient**. [After V. Henri (1872–1940), French physical chemist; Leonor Michaelis (1875–1949), German physician and biochemist; and Maude Menten (1879–1960), Canadian physician and biochemist.]

Michaelis pH function any one of a set of functions relating hydrogen concentration, [H⁺], to the acid dissociation constants for different stages of dissociation of a given polybasic acid.

Consider first the simplest example, that of a symmetrical dibasic acid, AH₂ (e.g. succinic acid). This can exist in three stages of dissociation, represented by the equilibria

where *K₁* and *K₂* are the acid dissociation constants for the respective stages of dissociation. For such a dissociation there are three Michaelis pH functions, *f*₀, *f*₁, and *f*₂, which are defined thus:

$$f_0 = 1 + K_1/[H^+] + K_1K_2/[H^+]^2$$

$$f_1 = 1 + [H^+]/K_1 + K_2/[H^+]$$

$$f_2 = 1 + [H^+]/K_2 + [H^+]^2/K_1K_2$$

The total concentration of acid of all forms, [A]_T, is given by

$$[A]_T = [AH_2] + [AH^-] + [A^{2-}]$$

by substitution for K_1 and K_2 it can be shown that

$$[A]_t = f_0[AH_2] = f_1[AH] = f_2[A^{2-}]$$

Hence it will be apparent that the reciprocals of the respective pH functions give the fractional concentrations of the various ionic forms of the acid at a given pH value. The theory of pH functions is independent of the chemical nature of the ionizing groups: the functions apply equally to molecules with identical ionizing groups (e.g. dicarboxylic acids, as above), to ampholytes (e.g. amino acids), and to molecules or parts of molecules in which the nature of the ionizing groups may not be known (e.g. the active centres of enzymes). For an unsymmetrical dibasic acid there are potentially four ionic forms, four dissociation constants, and thus four pH functions, but these are important in practice only if the pK values of the two dissociating groups are fairly close, as could be the situation at an active centre of an enzyme. If, on the other hand, the pK values are widely separated, as is the case with a typical amino acid, then there is effectively only one intermediate form and a set of three pH functions as above may be considered to apply.

micr+ see **micro+** (def. 2).

micra a plural of **micron**.

micrRNA *abbr.* for messenger-RNA-interfering complementary RNA (i.e. **antisense RNA**).

micro 1 (concerning something) very small (e.g. micro method). **2** short for a microcomputer.

micro+ 1 *symbol:* μ ; the SI prefix denoting 10^{-6} times. **2** or (*sometimes before a vowel*) **micr+** denoting very small or concerned with very small things (e.g. microbiology, microsome); abnormally small, underdeveloped (e.g. microcyte); on a small scale or concerned with small quantities (e.g. microanalysis, microbalance); of a small area or volume, or small part of a larger one (e.g. microenvironment). *Compare* **macro+**. **3** indicating amplification or magnification of something very small (e.g. microphone, microscope). **4** involving the use of a microscope (e.g. micrograph).

microaerophilic 1 describing an aerobic environment with a lower partial pressure of dioxygen than that under normal atmospheric conditions. **2** describing an organism whose maximal rate of growth occurs in such an environment.

microalbuminuria the excretion of plasma albumin in the urine at a rate above the normal range of values ($5\text{--}20 \mu\text{g min}^{-1}$) but below the threshold level ($300 \mu\text{g min}^{-1}$) for detection by routine dipstick methods and measurable only by radioimmunoassay (or other techniques of comparable sensitivity). The condition is associated with a general increase in vascular permeability and forms a sensitive indicator of diabetic nephropathy.

microanalysis any technique whereby very small amounts of substance may be analysed qualitatively or quantitatively. The term was originally used to indicate analysis of substances in the range 1–10 mg. —**microanalytic** or **microanalytical** *adj.*

microarray or **DNA chip** or **DNA microarray** or **gene expression array** a glass slide or bead whose surface bears numerous microscopic samples of DNA or other reagent in an orderly pattern. Microarrays are most commonly used for the simultaneous measurement of the expression levels of large numbers of genes. For example, entire cloned cDNA sequences or oligonucleotides can be bound to the slide, either by means of a robotic spotter or by direct synthesis on the array. A single slide may contain tens of thousands of spots, or addresses, each containing a copy of a specific DNA sequence. cDNA samples that have been reverse transcribed from a cellular RNA extract are then fluorescently labelled and hybridized to the array. The array is scanned with a fluorescent scanner, and the data collected and automatically analysed to quantify the relative amount of fluorescence and hence the relative levels of expression of each gene. *See also* **GeneChip array**.

microassay any technique whereby very small amounts of substance may be assayed. *Compare* **microanalysis**.

microbalance any balance designed to weigh very small quantities, typically between 1 μg and 1 mg.

microbe a common term for a microorganism, especially a pathogenic bacterium. —**microbial** *adj.*

microbial collagenase EC 3.4.24.3; *other names:* *Clostridium histolyticum* collagenase; clostridiopeptidase A; collagenase A; colla-

genase I; an enzyme that catalyses the digestion of native collagen in the triple-helical region at Xaa-|-Gly bonds. Some preference is shown for Gly at P3 and P1', Pro and Ala at P2 and P2', and hydroxyproline, Ala, or Arg at P3' (*see* **peptidase P-sites**).

microbiological of, pertaining to, or concerned with microbiology; effected by microorganisms.

microbiological assay any assay for a substance, especially an amino acid or vitamin, that is based on the extent of growth of a microorganism for which the analyte in question is an essential growth factor.

microbiology the science concerned with microorganisms, and with their interactions with other organisms and the environment. —**microbiologist** *n.*

microbody a cytoplasmic organelle, spherical or oval in shape, and 0.1–1.5 nm across, that is bounded by a single membrane and contains oxidative enzymes, especially those utilizing H_2O_2 . Microbodies include **glyoxysomes** and **peroxisomes**.

microbore high-pressure liquid chromatography or **microbore HPLC** a variant of **high-pressure liquid chromatography** in which a column of only about 1 mm diameter is used. The advantages of the technique include greater sensitivity and a much reduced solvent consumption.

microcalorimeter a calorimeter designed to measure continuous power outputs down to 1 μW , or heat pulses down to 200 μJ . —**microcalorimetry** *n.*; **microcalorimetric** *adj.*

microcapsule any very small thin-walled capsule of plastic, wax, etc., containing a liquid, powder, etc., from which the contents may be released (by heat, impact, radiation, dissolution, or other means) in order to fulfil some specific function. *See also* **microencapsulation**.

microcarrier any of a number of preparations of finely particulate, nontoxic, nonrigid, usually transparent material of density close to unity, e.g. dextran-based beads, that enable the growth of animal cells in suspension culture, especially on a large scale. Microcarriers permit the growth of anchorage-dependent cells as a monolayer on the surface of the particles. Generally, the cells may be easily harvested, e.g. by allowing the particles to settle and then treating with a proteinase such as trypsin.

microcell 1 a small, experimentally produced eukaryotic cell-like structure in which a limited amount of genetic material is contained in a micronucleus surrounded by a rim of cytoplasm and an intact cell membrane. It is useful as a vector for the transfer of a small number of chromosomes into a normal cell by virus-induced cell fusion. **2** any small **cell** (def. 2), commonly with a capacity less than 1 mL.

microchemistry chemistry on a very small scale, commonly handling less than 1 mg or 1 mL of material and often requiring special small apparatus. —**microchemical** *adj.*

microcin any of a number of microbial peptide toxins that have antibiotic action. They are of diverse structure and action. Examples include microcin E492, a 6 kDa polypeptide antibiotic. It forms cation-selective channels in planar phospholipid bilayers, leading to a loss of membrane potential. Another example is microcin B17 from *E. coli*. This is a glycine-rich peptide that inhibits DNA gyrase (*see* **(DNA) topoisomerase** type II). Microcin is classified in the TC system under number 1.C.58.

micrococcal of, pertaining to, or produced by micrococci; being a member of the genus **Micrococcus**.

Micrococcus a genus of Gram-positive, strictly aerobic, usually nonmotile coccoid bacteria of the family Micrococcaceae. The cells are commonly 1–2 μm in diameter.

microconcentrator a commercial device for the concentration and desalting of 'small' volumes (i.e. ≤ 2 mL) of biological samples.

microcrystal any very small crystal, especially one that is visible only under a microscope. —**microcrystalline** *adj.*

microcurie *symbol:* μCi or (*formerly*) μc ; a unit of (radio)activity or of radioactive material equal to 10^{-6} **curie** or 3.7×10^4 becquerel.

microdeletion a DNA/chromosomal deletion that is not detectable by conventional techniques such as **Southern blotting** or microscopy.

microdensitometry the measurement of **absorbance** (i.e. optical density) over a very small finite area, such as that viewed by an optical microscope. —**microdensitometric** *adj.*; **microdensitometer** *n.*

microdialyser or (*sometimes, esp. US*) **microdialyzer** a device for

microdialysis, especially one designed to minimize loss and dilution of samples.

microdialysis dialysis of a sample of small volume (commonly of less than 1 mL).

microdiffusion analysis *see* **Conway microdiffusion method**.

microdissection the dissection of small organisms or parts of organisms by means of mechanically controlled instruments viewed through an optical microscope.

microelectrode any electrode in which the sensitive element is very small and also often needle-like. It is useful for investigation of electrical phenomena in individual cells or in very small volumes.

microencapsulation the act or process of enclosing substances, solutions, etc. in **microcapsules**.

microenvironment a very small domain of the environment, such as that surrounding a single molecule or a functional group of a molecule, a single cell or organism, or a small group of cells or organisms. The term is used especially to distinguish zones of local difference in the overall environment.

microfarad *abbr.*: mfd; *symbol*: μF ; a unit of capacitance equal to 10^{-6} farad.

microfibre or (*US*) **microfiber** any fibre having a diameter in the range 0.1–1 μm , such as used in making glass microfibre filters.

microfibril any small fibril occurring in biological material that is distinguishable only by electron microscopy, especially one of a set that make up a fibril, e.g. in cellulose. —**microfibrillar** *adj.*

microfibrillar polysaccharide one of three groups of cell-wall polysaccharides characterized by solubility differences: the main component in the plant kingdom is **cellulose** but **chitin** is found in some fungi, β -1,4-mannans in some green algae (e.g. *Codiaceae*), and β -1,3-xylans in other green algae (e.g. *Bryopsidaceae*).

microfilament a type of **actin filament** that contributes to the cytoskeleton of eukaryotic cells. Microfilaments are elongated structures consisting of two strands of globular **actin** monomers twisted into a helix with 13.5 molecules per turn. Microfilaments form the major component of the cell's contractile machinery and are implicated in cell division, cell movement, muscle contraction, nerve outgrowth, tubular gland formation, gastrulation, and neurulation.

Compare **intermediate filament**, **microtubule**.

microfilter 1 any small filter, especially as used in microchemistry. **2** *see* **microporous filter**.

microfiltration filtration with a **microporous filter**.

microflora 1 a *collective name* for very small plants. **2** the flora of a **microhabitat**. **3** a *collective name* for all the microorganisms of a tissue or organ of an animal.

microfluorimeter an instrument for **microfluorimetry**.

microfluorimetry the measurement of intensity of fluorescence over a very small finite area, such as a single cell viewed under an optical microscope. —**microfluorimetric** *adj.*

microfold cell *see* **M cell**.

microforge a device by means of which micropipettes, very small glass tools, etc. can be made while being viewed under a low-power microscope.

microfungus (*pl.* **microfungi**) any fungus whose vegetative thallus or fruiting body is too small to be seen easily with the unaided eye.

Compare **mould**.

microglobulin 1 any plasma **globulin** molecule or globulin fragment of less than ≈ 40 kDa, e.g. **Bence-Jones protein**, β_2 -**microglobulin**. **2** a *term sometimes used to refer to* 7S immunoglobulins such as IgG. *Compare* **macroglobulin**.

β_2 -microglobulin or **betamicroglobulin** a human plasma protein, of 11.8 kDa and containing 99 amino-acid residues, that in size, primary structure, and tertiary structure strongly resembles a single domain of the constant region of immunoglobulin molecules: it is a constituent of class I **major histocompatibility complexes**. Plasma levels may be elevated in hepatobiliary disease, chronic active hepatitis, and alcohol-induced liver cirrhosis.

microgram 1 *symbol*: μg or (*esp. in pharmacy*) *mcg*; a unit of mass equal to 10^{-9} kilogram or 10^{-6} gram; *formerly called* gamma (*symbol*: γ). **2** an *alternative name (sometimes) for* **micrograph**.

micrograph or (*sometimes*) **microgram** a graphic reproduction of the image of an object as seen through a microscope.

microhabitat any habitat that is small or limited in extent and differs in character from a larger, surrounding habitat.

microheterogeneous describing a preparation of a biopolymer that superficially appears to be homogeneous but that, on refined analysis, shows slight differences in size, sequence, charge, state of aggregation, or other properties of its molecules. Such differences are believed, at least in some instances, to be attributable either to artefactual changes or to genetic differences. —**microheterogeneity** *n.*

microincineration a technique for examining the distribution of minerals in tissue sections or microorganisms. The specimen is placed on a slide, the organic material burned away in a furnace, and the nature and position of the mineral ash determined by microscopy.

microinject to inject liquid into a single cell or nerve fibre using a micropipette. —**microinjection** *n.*

microiontophoresis **iontophoresis** (def. 2) applied to very small areas of tissue.

micro-Kjeldahl method an adaptation of the **Kjeldahl method** for determining small amounts of nitrogen, in the range 0.1–1.0 mg. A correspondingly small flask, commonly known as a **micro-Kjeldahl flask**, is used for the digestion, and a **Markham still** may be used for the steam distillation.

microlitre or (*esp. US*) **microliter** *symbol*: μL or μl ; a unit of volume equal to 10^{-6} litre; *formerly called* **lambda** (*symbol*: λ).

micromanipulation the techniques and practice of performing very delicate operations, such as microdissection, microinjection, or the isolation of single cells, under an optical microscope, usually with the aid of a **micromanipulator**.

micromanipulator an instrument used in conjunction with an optical microscope for holding and manipulating very small instruments and specimens in the field of view.

micrometer 1 any instrument or device for measuring very small distances or angles. **2** or **micrometer gauge** a device for measuring small distances, thicknesses, diameters, etc. with great accuracy. **3** *the US spelling of* **micrometre**.

micrometer burette a **micrometer syringe** adapted for use as a burette.

micrometer pipette a **micrometer syringe** adapted for use as a pipette.

micrometer screw a screw with a fine thread of accurate and consistent pitch.

micrometer syringe a syringe for the accurate delivery of small volumes of liquid in which the plunger of the syringe is driven by a calibrated micrometer screw.

micrometre or (*US*) **micrometer** *symbol*: μm ; a unit of length equal to 10^{-6} metre; *formerly called* **micron** (*symbol*: μ).

micromicro+ *symbol*: $\mu\mu$ a *former name for* **pico+**.

micromodification alteration of the covalent structure of a macromolecule, especially a histone, by the addition of various groups, e.g. acetyl, methyl, phosphate, after the initial biosynthetic process is terminated.

micromolar *symbol*: μM or μmM ; describing a solution containing one micromole of solute per litre of solution, or a specified multiple or fraction thereof; used also of an amount-of-substance concentration similarly expressed.

micromole *symbol*: μmol ; a unit of amount of substance equal to 10^{-6} mole.

micromolecule any (type of) molecule composed of a relatively small number of atoms. In practice the term is usually taken to mean any (type of) molecule that is capable of passing through the pores of dialysis tubing (as generally used) and that thus has a mass less than about 10 kDa. —**micromolecular** *adj.*

micron (*pl.* **microns** or **micra**) *symbol*: μ ; a *former term for* **micrometre**. **micronucleus** a eukaryotic cell nucleus with less than the normal complement of chromosomes, produced experimentally by incubation of a cell with colchicine. —**micronuclear** *adj.*

micronutrient any chemical element that is required by living organisms in tiny quantities only, also known as **trace element**. The term is often extended to include organic compounds such as vitamins.

microorganism any noncellular or unicellular (including colonial) organism, most of which are too small to be seen with the unaided eye. Microorganisms comprise bacteria (including cyanobacteria),

lichens, microfungi, protozoa, rickettsiae, virinos, viroids, and viruses, and also some algae; all prokaryotes are included. *See also* **microbe**.

microperoxisome (*sometimes*) a type of small **peroxisome**, 150–250 nm in diameter, found in all mammalian cells.

microphthalmia transcription factor *see* **MITF**.

micropinocytosis (*sometimes*) a form of **pinocytosis** occurring in higher animals, especially in the transfer of dissolved macromolecules from the blood to the cytoplasm of cells, in which the pinosomes formed are very small (**micropinosomes**) and can only be observed in the electron microscope.

micropipette or (*US*) **micropipet** any pipette calibrated to contain or deliver a volume in the range 5–500 μL .

micropore any pore (in a gel or porous solid) whose width does not exceed about 2.0 nm. *Compare* **macropore**, **mesopore**. —**microporous** *adj.*

microprocessor a single integrated electronic circuit designed to carry out a specific set of operations, e.g. as the central processor of a computer or a control system.

Microprocessor the smaller of two nuclear complexes containing **Drosha** and **Pasha** and involved in processing **pri-miRNA** to **pre-miRNA**.

microRNA *see* **miRNA**.

microsatellite a repeating DNA segment that is similar to a **mini-satellite** except that the overall range of size is smaller and the base core repeat unit involves a two or four nucleotide pair repeat motif. They are so named because of their resemblance to **satellite DNA** in having tandem repeats. The number of copies of the repeats varies not only between individuals but also between the two chromosomes of a pair. Their highly polymorphic nature has made them invaluable for analysis of pedigrees and in linkage analysis.

microscope an instrument consisting of a lens or a combination of lenses that uses light or other electromagnetic radiation to make enlarged images of objects that are invisible to, or not easily seen by, the unaided eye. *See also* **electron microscope**, **phase-contrast microscopy**.

microscopic 1 of a size that is not visible (in detail) to the unaided eye. **2** concerned with small units. **3** relating to the behaviour of individual molecular entities. **4** or **microscopical** of, pertaining to, or using a microscope. *Compare* **macroscopic**. —**microscopically** *adv.*

microscopic equilibrium constant any constant describing the equilibrium of the interconversion of two particular molecular entities. *Compare* **intrinsic constant**, **macroscopic equilibrium constant**.

microscopic reversibility a thermodynamic principle requiring that at equilibrium the reaction pathway for the reverse of any particular chemical reaction is the exact opposite of the pathway for the forward reaction, i.e. both forward and backward reactions must pass through the same transition states or intermediates and occur with equal frequency.

microscopy the art and practice of using a microscope; investigation with a microscope.

microsecond *symbol:* μs ; a unit of time equal to 10^{-6} second.

microsequenator an apparatus for microsequencing (*see* **microsequence**).

microsequence to sequence (def. 3) a biopolymer using a very small sample, e.g. 5–100 pmol of a protein.

microsolute an *operational term used to describe* any diffusible solute in a solution that also contains nondiffusible macromolecular solute(s).

microsomal of, pertaining to, or containing **microsomes**; being in the **microsomal fraction** of a homogenate of a cell or tissue.

microsomal fraction an *operational term for* the subcellular fraction of a homogenate of a eukaryotic cell or tissue that, on differential centrifugation, is sedimented at $10^5 g$; the fraction from some tissues, such as liver, although consisting largely of microsomes, commonly also contains free ribosomes and fragments of the plasma membrane, of the Golgi apparatus, of mitochondria, and of other subcellular structures. The morphological constituents differ according to the tissue from which the fraction was derived.

microsomal triglyceride transfer protein a protein of the endoplasmic reticulum involved in the assembly and secretion of apolipoprotein B-containing plasma lipoproteins in intestinal mucosa and liver. It is a heterodimer of an 88 kDa subunit and a pro-

tein disulfide isomerase. Mutations in the gene for the first subunit, at 4q22-q24 (which encodes an 894-residue protein), are associated with **abetalipoproteinemia**.

microsome any of the small, heterogeneous, artefactual, vesicular particles, 50–150 nm in diameter, that are formed when some eukaryotic cells are homogenized and that sediment on centrifugation at $10^5 g$. Microsomes are formed mostly from disrupted endoplasmic reticulum membranes but some arise from the plasma membrane. Those formed from rough endoplasmic reticulum are studied with ribosomes on the outside (**rough microsomes**); those formed from smooth endoplasmic reticulum and from plasma membrane have no adhering ribosomes (**smooth microsomes**).

microspectrophotometer an instrument, consisting of a microscope and a spectrophotometer, used for measuring light of selected frequencies passing through, or reflected from, a very small specimen, e.g. a cell or a subcellular structure.

microspectrophotometry **spectrophotometry** applied to a very small specimen, using a microspectrophotometer. —**microspectrophotometric** *adj.*

microsphere one of a preparation of spherical particles of known and uniform size, usually in the range 10–40 μm in diameter, and prepared from, e.g., serum albumin or an ion-exchange resin, that may be labelled with an appropriate radionuclide and used in studies of the circulation of the blood in health or disease.

microspore the smaller of the two types of spores produced by the heterosporous plants. In seed plants the microspore is the cell from which the pollen grain develops. —**microsporous** *adj.*

microstructure an *alternative term for* **fine structure**.

microsyringe a syringe for delivering volumes of gases or liquids in the range 0.1–500 μL .

microtitre plate or (*esp. US*) **microtiter plate** any rectangular plate usually made of polycarbonate and containing wells in a gridlike pattern. Most usually the plate has 96 wells arranged in the form of eight rows of 12 columns, each well having a capacity of a few hundred microlitres. They are commonly used for **enzyme-linked immunosorbent assay** (ELISA) or other immunological reactions, or for the growth of small cultures of microorganisms or eukaryotic cells.

microtome an instrument for cutting thin sections of objects, e.g. tissues or cells, preparatory to microscopic observation.

microtrabecular lattice an irregular, three-dimensional lattice of very fine strands, up to 15 nm in diameter, sometimes termed **microtrabeculae**, that can be visualized in the cytoplasmic ground substance of eukaryotic cells by high-voltage electron microscopy. It forms part of the cytoskeleton.

microtubule any of the long, generally straight, hollow tubes of internal diameter 12–15 nm and external diameter 24 nm found in a wide variety of eukaryotic cells. Each consists (usually) of 13 protofilaments of polymeric **tubulin**, staggered in such a manner that the tubulin monomers are arranged in a characteristic helical pattern on the surface, and with the α/β axes of the tubulin parallel to the long axis of the tubule. Microtubules exist in equilibrium with a pool of tubulin monomers in the cytoplasm and can be rapidly assembled and disassembled in response to various physiological stimuli; there are also a number of **microtubule-associated proteins**. Most microtubules in a cell appear to be initiated at **microtubule-organizing centres** and some may also become attached to the **kinetochores**. Microtubules are involved in force generation in cilia and flagella, where they exist in a characteristic $9 + 2$ array (a ring of nine doublet microtubules with two single microtubules in the centre), and the integrity of the microtubule network appears to be necessary for certain aspects of mitotic spindle function and for the saltatory movement of cell organelles. Taxol prevents depolymerization of microtubules, and is thus antimitotic. *Compare* **intermediate filament**, **microfilament**.

microtubule-associated protein *abbr.:* MAP; any protein that binds to **microtubules**, and modifies their properties, including proteins that induce polymerization of purified tubulin and become associated with the newly formed microtubules. Many different kinds have been found, including structural proteins and motor proteins. MAP 1 is a structural protein involved in the filamentous cross-bridging between microtubules and other skeletal elements. The role of MAP2 is unclear; in neuronal cells, it is confined to the cell

body and dendrites. It changes structurally during development by alternative splicing mechanisms. **Dynein** is an example of a motor protein MAP. *Compare tau protein. See also MAP kinase.*

microtubule-organizing centre a region near the centre of a eukaryotic cell consisting typically of two **centrioles** at right angles to each other and surrounded by a complex of associated proteins. The centrioles and their satellite proteins serve as initiating sites for the assembly of microtubules.

microvillin a protein of the microvilli of rat mammary cells, M_r 200 000.

microvillus (*pl. microvilli*) any of the very small, finger-like projections that occur on the exposed surfaces of epithelial cells, especially where cellular function requires a maximal surface area for absorption or secretion, as in the proximal renal tubule and the small intestine, where they constitute the brush border. The projections are about 1–2 μm long and 100 nm in diameter. The core of a microvillus contains a bundle of about 40 actin filaments of uniform polarity with their 'barbed' (+) ends anchored in a cap of ill-defined amorphous material in the microvillar tip. At the base the actin filaments extend into the perpendicular network, also made up largely of actin, known as the terminal web. In the core the actin filaments are bound together by the actin-binding proteins fimbrin and villin. The renal and intestinal microvilli contain a wide range of hydrolases that are integral membrane proteins; their hydrophilic domains, containing the catalytic sites, face outwards from the cell. —**microvillar** *adj.*

microvolume a very small volume, commonly in the range 1–100 μL .

microwave radiation electromagnetic radiation of wavelengths in the range 1–300 mm (frequencies 1–300 GHz), lying between infrared radiation and most radiofrequency radiation.

Midas *abbr. for* metal-ion-dependent adhesion site; a region that binds Ca^{2+} in the N-terminal region of the β chain of some **integrins**.

middle molecule *a term sometimes used for* any compound in the range 350–2000 Da that accumulates in the body fluids of persons with uremia.

middle T antigen *see* **T antigen** (def. 1).

midkine *other names:* neurite outgrowth-promoting protein; midgestation and kidney protein; amphiregulin-associated protein (*abbr.:* ARAP); a heparin-binding growth/differentiation factor with neurite-promoting activity. It is a cell-surface or basement-membrane protein, induced by retinoic acid and similar to **pleiotrophin**. The midkine gene product is primarily detected in the embryonic period, whereas pleiotrophin is expressed most strongly in the early neonatal period.

midnight zone (*in sequence analysis*) a region of identity where sequence comparisons fail completely to detect structural similarity. Falling in the lower reaches of the **twilight zone**, it represents the theoretical limit of sequence-based comparison methods.

midpoint 1 the point on a line, or a graph, that is equidistant from either end of the line or from two inflections in the graph. **2** a point in time that is half way between the beginning and the end of an event, or a series of events.

midpoint potential the **electrode potential**, at a given pH and temperature and 1 atm H_2 , at the midpoint of a redox titration when the activities of the reductant and the oxidant are equal.

MIF *abbr. for* **1** (macrophage) migration inhibition factor. **2** melanotropin release-inhibiting factor (i.e. **melanostatin**). **3** Müllerian inhibitory factor.

mifepristone *see* RU-486.

migratase *an old name for* **mutase**; e.g. lysolecithin migratase is an old name for lysolecithin acylmutase (EC 5.4.1.1).

migrate (*in chemistry*) (of atoms, ions, or molecules) to move from one region of a solution to another, or from a solution in one compartment to a solution in another compartment, under the influence of an electric or a centrifugal field or by diffusion. —**migration** *n.*

migration inhibition factor *abbr.:* MIF; *see* (macrophage) **migration inhibition factor**.

MIH *abbr. for* melanotropin release-inhibiting hormone (i.e. **melanostatin**).

MIL the avian homologue of **RAF**; *v-mil* is the oncogene of the avian

retrovirus Mill-Hill-2, which also carries *v-myc*. It codes for a serine/threonine kinase of the **RAF/MOS** subfamily of unknown function but exhibiting homology with Src and related proteins (*see src*).

milieu (*pl. milieus or milieux*) environment or setting.

milieu intérieur (*French*) the internal environment of a multicellular organism that surrounds the tissues and cells.

milk 1 the white liquid produced and secreted by the mammary glands of mature female mammals for the nourishment of their young. The milk of certain mammals, especially cows, is used as a food by humans, either as liquid milk or in the production of butter, cheese, etc. **2** any of various natural or manufactured liquids that have the appearance or consistency of milk, e.g. coconut milk, milk of magnesia. **3** to squeeze or draw milk from; to yield milk. — **milky** *adj.*

milk factor *an alternative name for* **Bittner factor**.

milk sugar *an old name for* **D-lactose**.

Miller index (*in crystallography*) any of a set of three integers that determine the position of a face, or internal plane, of a crystal in relation to three crystallographic axes. They are determined on the basis of the reciprocals of the intercepts of the face or plane on the crystallographic axes. [After W. H. Miller (1801–80).]

milli+ 1 *symbol:* m; an SI prefix denoting 10^{-3} times. **2** *prefix* denoting one-thousandth.

millicurie *symbol:* mCi or (*formerly*) mc; a unit of (radio)activity or of radioactive material equal to 10^{-3} **curie** or 3×10^7 becquerel.

milliequivalent *symbol:* mequiv or meq or mEq; a unit of amount of substance equal to 10^{-3} **equivalent** (def. 3); (mmol recommended).

milligram *symbol:* mg; a unit of mass equal to 10^{-6} **kilogram** or 10^{-3} gram.

millilitre or (*US*) **milliliter** *symbol:* mL or ml; a unit of volume equal to 10^{-3} **litre**. It is now identical to the cubic centimetre; i.e. $1 \text{ mL} = 1 \text{ cm}^3 = 10^{-6} \text{ m}^3$.

millimetre or (*US*) **millimeter** *symbol:* mm; a unit of length equal to 10^{-3} **metre**.

millimetre of mercury *symbol:* mmHg; a non-SI unit of pressure defined as the pressure exerted by a column exactly 1 mm high of a fluid of density that is exactly $13.5951 \text{ g cm}^{-3}$ in a place where the acceleration of free fall is exactly $980.665 \text{ cm s}^{-2}$. Its use is deprecated. $1 \text{ mmHg} = 1 \text{ torr} = 133.32 \text{ pascal}$.

millimicro+ *a former name for* **nano+**.

millimicron (*pl. millimicrons or millimicra*) *symbol:* $\text{m}\mu$; *a former name for* **nanometre**.

millimolar *symbol:* mM or mM; describing a solution containing one millimole per litre of solution, or a specified multiple or fraction thereof; the term is also used of an amount-of-substance concentration similarly expressed.

millimole *symbol:* mmol; a unit of amount of substance equal to 10^{-3} **mole**.

Millipore 1 *the proprietary name for* a range of microporous and other types of membrane filters manufactured by the Millipore Corporation. **2** a water purification system, manufactured by the same company and based on reverse osmosis.

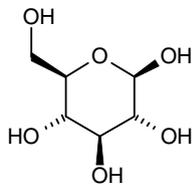

millisecond *symbol:* ms; a unit of time equal to 10^{-3} **second**.

Millon's reaction the formation of red complexes when compounds containing the hydroxybenzene group are heated with **Millon's reagent**. The reaction is given by proteins that contain one or more tyrosine residues. [After Auguste Millon (1812–67), French chemist.]

Millon's reagent a 15% solution of mercuric sulfate in 15% sulfuric acid. This is added to the test sample solution, which is then heated in a boiling water bath for 10 min. After cooling, a 1% aqueous solution of sodium nitrite is added to the cooled reaction mixture. It gives **Millon's reaction** with compounds containing the hydroxybenzene group.

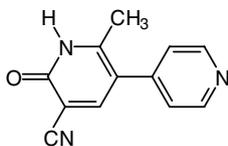

Mills perspective representation or **Mills representation** a diagrammatic way of unambiguously representing the structural formulae of carbohydrates and their polycyclic derivatives to show on a plane surface the relative configurational arrangements of substituents and bridges. It is particularly useful in instances where the **Haworth representation** is inconvenient, e.g. for depicting saccharides with substituents that bridge two positions on the ring. The carbohydrate in question, or its derivative, is drawn with single rings and

fused rings in the plane of the surface, and with bonds to substituents or bridges above or below the plane of the rings drawn with dark lines (often wedge-shaped) or broken lines, respectively (as is customary in representations of steroids and terpenes). Hydrogen atoms in the angular positions at ring junctions are always shown but those at points of substitution may be omitted. Like **Fischer projections**, but unlike Haworth representations, Mills representations may be rotated in the plane of the paper without alteration of their significance. It was proposed primarily for carbohydrate structures, but resembles systems used for other types of molecule, e.g. steroids.

β -D-glucose

milrinone 1,2-dihydro-6-methyl-2-oxo-5-(4-pyridinyl)nicotinonitrile; a phosphodiesterase inhibitor with vasodilating and cardio-stimulant activity.

mimetic imitating closely.

+mimetic *suffix* (esp. in pharmacology) denoting having a similar effect to the substance or action indicated.

min *symbol* for minute.

Min *abbr.* for Minute; a system of bacterial proteins responsible for correct localization of the **Z ring** to the mid-cell region of the plasma membrane inner surface in preparation for cell division. MinC and MinD form a complex on the inner cell-membrane surface and inhibit Z ring assembly. MinE relieves this inhibition in the mid-cell region.

mince **1** to disrupt tissue with a **tissue grinder** to the level at which there is extensive, but incomplete, rupture of cells. **2** the preparation resulting from the action of a coarse tissue grinder.

mineral **1** any naturally occurring inorganic substance of a type often obtained by mining, e.g. coal, stone, petroleum. **2** any of a class of naturally occurring inorganic substances, of definite chemical composition and physical properties and often crystalline in character. **3** of, pertaining to, or being a **mineral** (def. 1, 2).

mineralize or **mineralise** (of an organic material) to convert into, or impregnate with, a mineral or minerals. —**mineralization** or **mineralisation** *n.*

mineralocorticoid or **mineralocorticosteroid** any naturally occurring or synthetic hormonal **corticosteroid** that acts primarily on water and electrolyte balance by promoting the renal retention of sodium ions and excretion of potassium ions. Mineralocorticoids are produced in the outer layer (zona glomerulosa) of the adrenal cortex. **Aldosterone** is the most potent of the naturally occurring mineralocorticoids. *Compare* **glucocorticoid**.

mineralocorticoid receptor a nuclear receptor (984 amino acids) of the steroid hormone type that binds and mediates the biological effects of aldosterone. Loss-of-function mutations result in pseudo-hypoaldosteronism type 1. Gain-of-function mutations lead to an early-onset type of hypertension that is exacerbated by pregnancy.

mini+ *comb. form* denoting miniature; of smaller than usual dimensions.

miniature inverted-repeat transposable element *abbr.:*

MITE; a transposable element containing almost identical sequences of ≈ 400 bp flanked by characteristic inverted repeats of ≈ 15 bp. MITEs are too small to encode protein; they are ubiquitous in genome sequences, accounting for 5% or more of some genomes (e.g. rice).

micell **1** a small cell-like body arising from a polar region of a rod-shaped bacterium by aberrant cell division. It is spherical or near-spherical in shape and devoid of chromosomal DNA; hence it does not grow or divide and is normally unable to synthesize nucleic acid or protein (but may do so if a plasmid is introduced). **2** an experimentally produced eukaryotic cell in which an intact cell nucleus is surrounded by scant cytoplasm and a cell membrane. It is prepared by enucleation of a normal mononucleate cell.

miniexon a small exon, as found in the troponin T gene.

minigastrin a form of the peptide hormone **gastrin** that contains 14 amino-acid residues. It has been isolated from tumour tissue and corresponds to residues 5–17 of human gastrin 1, having the sequence LEEEEAYGWLDFH-amide.

minima a plural of **minimum**.

minimal of, being, or constituting the minimum; the least possible.

minimal medium a (synthetic) culture medium containing only those compounds essential for the growth of a wild-type organism and that is not able to support growth of an auxotroph.

minimum (*pl.* **minimums** or **minima**) **1** the least quantity, degree, or value possible or permissible. **2** (*in mathematics*) a value of a function that is less than that of any neighbouring value. **3** of, or pertaining to, a minimum or minimums.

minimum evolution a principle of phylogenetic reconstruction based on minimization of the sum of the lengths of tree branches. From all possible tree topologies over a defined set of taxa, the minimum evolution topology is the one that requires the shortest overall branch lengths.

minimum inhibitory concentration *abbr.:* MIC; the lowest concentration of a drug, or other substance, that just inhibits the growth of a given test organism (bacterium, etc.) in defined conditions.

minimum lethal dose *abbr.:* MLD; the minimum dose of a toxic substance, or organism, that will kill, within a specified time, all the animals in a test group to which it is administered.

minimum (relative) molecular mass or (*formerly*) **minimum molecular weight** the (relative) molecular mass of a compound as determined by the assay of one of its structural elements, e.g. a metal atom, a ligand, a terminal residue, etc., assuming that there must be at least one such structural element in each molecule of the compound.

minisatellite a repeat DNA segment comprising short head-to-tail tandem repeats giving **variable number tandem repeat**-type polymorphisms, with approximate size between 1 and 30 kb. The name derives from the fact that repeat DNA segments were originally found in **satellite DNA**, but the overall size of the minisatellite segments and the length of individual repeats are smaller, and satellite peaks are not seen on centrifugation.

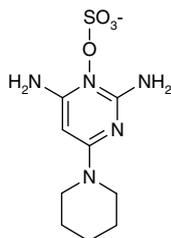

minivial a very small vial, especially a low-capacity container that can be inserted into a normal-sized sample vial used in liquid scintillation counting, to enable the (radio)activity of small-volume samples to be determined more efficiently.

minor base *see* **minor nucleoside**.

minor groove the smaller and shallower of the two grooves on the surface of a double-helical DNA molecule. *Compare* **major groove**.

minor nucleoside a nucleoside containing any of a group of purine or pyrimidine bases that occur in small amounts in most nucleic acids but in relatively large amounts in **transfer RNA** molecules from all organisms; they are sometimes known as 'odd bases'. The modifications range from the simple methylation of bases or ribose sugar residues to very complex substitutions, take place after transcription of the transfer RNA genes, and are thought to be related to the stability of the tertiary structure. A typical modified nucleoside is **pseudouridine**. *See also* **wyosine**.

minoxidil 6-(1-piperidinyl)-2,4-pyrimidinediamine-3-oxide; an anti-hypertensive agent and hair growth promoter. It is activated by sulfate conjugation to the active metabolite minoxidil sulfate.

minoxidil sulfate

minuend (*in mathematics*) the number (or quantity) from which another number (or quantity), the subtrahend, is to be subtracted.

minus end the end of a microtubule or actin filament at which the addition of monomers occurs least readily; the 'slow-growing' end of a microtubule or actin filament. The minus end of an actin filament is also known as the pointed end. *Compare plus end.*

minus 10 region and **minus 35 region** regions in the **promoter** defined by the number of nucleotides 5' from the first nucleotide transcribed, i.e. on the **coding strand**. The first nucleotide (the start site) of a transcribed DNA sequence is denoted as +1, the second +2; the nucleotide preceding the start site is denoted as -1. The most conserved sequence upstream (towards the 5' terminus) of DNA in *Escherichia coli* is a hexamer centred at the -10 position (*see* **Pribnow box**). It has a consensus sequence of TATAAT in which the leading TA and final T are highly conserved. -35 is the centre point of a consensus sequence involved in RNA polymerase recognition, TTGACA.

minus strand 1 the complementary strand to the parental polynucleotide strand – the **plus strand** (def. 1) – in bacteriophages whose genomes consist of duplex RNA. **2** any polynucleotide strand (RNA or DNA) in a viral genome that is complementary to the virus-specified mRNA – the **plus strand** (def. 2). **3** (*sometimes*) an *alternative term* for **coding strand** (of genetic duplex DNA).

minute 1 *symbol:* min; a non-SI unit of time equal to 60 seconds. **2** *symbol:* ' ; a unit of plane angle equal to ($\pi/10\ 800$) radians, or 0.291 milliradians. There are 60 seconds (of arc) in one minute (of arc), and 60 minutes in one degree (of arc). **3** (*in genetics*) an empirical unit of distance between genes in a bacterial chromosome, being a measure of the time taken, in minutes, for the transfer of a particular gene during bacterial conjugation relative to an arbitrarily standardized selected origin.

7-minute phosphate or **10-minute phosphate** *see* **labile phosphate**.

MIP *abbr.* for macrophage inflammatory protein.

mi protein a basic helix-loop-helix leucine-zipper protein that, as a homodimer, binds promoter regions of melanocyte-specific genes (e.g. tyrosinase). Mouse and human proteins (both ≈ 415 amino acids) share 95% sequence homology. At least a dozen mutations cause a type of Waardenburg syndrome that includes white forelock, heterochromia iridis, and congenital hearing loss. The protein is named after the microphthalmia-associated transcription factor of mouse.

miRNA *abbr.* for microRNA; *other name:* tiny RNA; any of various RNA species that are 21–25 nt long and may be single- or double-stranded. They have been found in animals, including *Drosophila* and *Caenorhabditis elegans*, and in plants. The term encompasses small interfering RNA (**siRNA**) and small temporal RNA (**stRNA**), as well as miRNA proper. miRNAs are transcribed as parts of longer RNA molecules and processed in the nucleus by the **dsRNA** ribonuclease **Drosha** to hairpin structures 70–100 nucleotides long. These are transported to the cytoplasm where they are digested to 21–23-mers by the dsRNA ribonuclease **Dicer**. Single-stranded miRNAs bind to complementary sequences in mRNA thereby inhibiting translation. Over 100 miRNA species have been found in *Arabidopsis thaliana*, of which some 16 are similar to species characterized from animals. They exhibit diverse developmental and tissue-specific expression profiles and are involved in a wide range of gene regulatory processes.

mirror (*in informatics*) an exact copy of a server made at a different

location, to spread the load of traffic and hence facilitate access to that server. Busy servers may have many mirrors (e.g. EXPASY).

misacylate or **mischarge** to acylate (a transfer RNA molecule) with an aminoacyl group other than the specific one. —**misacylation** *n.*

mischarge an *alternative term* for **misacylate**.

miscible (of two or more particular liquids) capable of being mixed together to give a homogeneous liquid. Particular liquids may be completely miscible or miscible only in certain proportions. *See also proofreading.* —**miscibility** *n.*

mismatch repair a system for the correction of errors introduced during DNA replication when an incorrect base, which cannot form hydrogen bonds with the corresponding base in the parent strand, is incorporated into the daughter strand. **Excinucleases** recognize a pair of non-hydrogen-bonded bases and cause a segment of polynucleotide chain to be excised from the (less methylated) daughter strand, thereby removing the mismatched base. The resulting gap is then filled by the actions of DNA polymerase I and DNA ligase.

mispairing the occurrence of a base in one polynucleotide strand of duplex DNA that is not complementary to the corresponding base in the other strand.

missense codon a particular codon that has been altered so that it codes for an amino-acid residue different from the one for which it normally codes.

missense mutation any mutation causing a base substitution in a gene that results in the incorporation of an incorrect amino-acid residue at a specific position in the polypeptide gene product. *Compare nonsense mutation, samesense mutation.*

mistranslation the insertion at a specific position in a polypeptide chain of an amino-acid residue that is not indicated by the corresponding codon in the mRNA molecule.

MIT *abbr.* for (3-)monoiodotyrosine.

Mitchell hypothesis the hypothesis, formulated principally by the British biochemist Peter Dennis Mitchell (1920–92), that mitochondrial systems can be driven by proton and electrical gradients that build up across membranes, a mechanism now referred to as **chemiosmotic coupling**.

MITE *abbr.* for miniature inverted-repeat transposable element.

MITF *abbr.* for microphthalmia transcription factor; a protein (419 amino acids) that shows 91% sequence homology in mouse and human. It is a basic helix-loop-helix leucine zipper transcription factor expressed in the neural crest, eye, and ear during development. Mutations lead to microphthalmia in mouse, and to Waardenburg syndrome type 2 in human.

mitochondria the plural of **mitochondrion**.

mitochondriac a biochemist with a chronic and unusually intense interest in mitochondria.

mitochondrial carrier any of a family of at least 13 metabolite transporters of the inner mitochondrial membrane. They consist of ≈ 300 amino acids organized into three homologous repeats, each of ≈ 100 residues and containing two transmembrane segments. They probably function as homodimers and serve as antiporters (e.g. for oxaloacetate/citrate, glutamate/aspartate, malate/2-oxoglutarate, citrulline/ornithine, and ATP/ADP pairs). *See also mitochondrial carrier protein.*

mitochondrial carrier protein any of various proteins involved in the translocation of small molecules across the mitochondrial inner membrane. Many are translocases using an **antiport** mechanism, and include carriers for pyruvate (antiport molecule is OH⁻), phosphate (malate), citrate (malate), phosphate (OH⁻), ADP (ATP), aspartate (glutamate), and malate (2-oxoglutarate); e.g., ADP/ATP translocase 1 of yeast; this is an integral inner membrane protein, with a tripartite structure, each repeated segment comprising ~ 100 residues and containing two transmembrane domains, one if which is more hydrophobic than the other. *See also OGCP.*

mitochondrial disease any disease that results from a mutation in mitochondrial DNA. Such diseases are transmitted maternally, are usually of early onset and rapidly progressive, and may involve organs that are seemingly unrelated embryologically or physiologically. Common clinical features include blindness, deafness, myopathy, cardiomyopathy, encephalopathy, diabetes mellitus, renal dysfunction, or liver disease. Among the best characterized are:

MELAS (mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes); **MERFF** (myoclonus epilepsy with ragged-red fibres); **Leber's hereditary optic neuropathy**; **Kearns-Sayre syndrome**; **Leigh syndrome**; aminoglycoside-induced deafness; and diabetes mellitus and deafness. The genetic causes of some of these are heterogeneous.

mitochondrial DNA *abbr.*: mtDNA; DNA that is contained, replicated, and expressed in mitochondria. mtDNA is double-stranded in almost all organisms studied; that from mammals has a contour length of $\approx 5 \mu\text{m}$, about 15 kilobases, while that from protozoa and fungi is about five times larger. Human mtDNA (16 569 bp) codes for two types of rRNA molecules, 22 types of tRNA molecules, and 13 proteins. mtDNA is transmitted maternally, i.e. with the mitochondria of oocytes. The code in mtDNA differs in some respects from that in nuclear DNA (*see* **genetic code**). *See* **mitochondrial disease**.

mitochondrial fission protein any protein involved in fission of mitochondria in eukaryotes. In yeast, three proteins (Fis1, Dnm1, and Mdv1) form the constriction ring around the outer membrane, while one protein (Mgm1) forms a ring on the outer surface of the inner membrane.

mitochondrial fraction *an operational term* for the more rapidly sedimenting components (for example 10 000–15 000 *g* for 30 min) of the **cytoplasmic fraction** of a homogenate of eukaryotic cells or tissue. It generally consists predominantly of mitochondria but may also contain varying numbers of secretion granules, lysosomes, microbodies, or other intracellular organelles.

mitochondrial plasmid DNA a distinct class of genetic elements, found in certain wild-type strains of *Neurospora*, that show virtually no sequence homology with standard mitochondrial DNA (mtDNA) in DNA–DNA hybridization experiments and achieve high copy number without suppressive behaviour towards wild-type mtDNA.

mitochondrial matrix the gel-like material, with considerable fine structure, that lies in the matrix space, or lumen, of a **mitochondrion**. It contains many enzymes, including ones involved in fatty-acid oxidation and enzymes of the tricarboxylic-acid cycle, amino-acid metabolism, urea cycle, and porphyrin synthesis.

mitochondrial processing peptidase EC 3.4.99.41; an enzyme that catalyses the cleavage of the leader peptide from precursor proteins imported into the mitochondrion, typically ones with Arg in position P2 (*see* **peptidase P-sites**). These enzymes resemble in sequence **preurein-leader peptidase**. In *Neurospora crassa* the enzyme consists of a catalytic subunit and an enhancer subunit. Both are transmembrane proteins. The enzyme requires the presence of divalent cations for activity.

mitochondrial RNA *abbr.*: mtRNA; any RNA molecules that are complementary to genes in mitochondrial DNA.

mitochondrial state *see* **respiratory state (of mitochondria)**.

mitochondrial trifunctional protein *see* **acyl-CoA dehydrogenase**.

mitochondrion (*pl.* **mitochondria**) a semiautonomous, self-replicating organelle that occurs in varying numbers, shapes, and sizes in the cytoplasm of virtually all eukaryotic cells. It is the site of tissue respiration (*see* **respiratory chain**, **oxidative phosphorylation**). Conventionally, mitochondria are represented as elongated cylinders with a diameter of 0.5–1.0 μm ; however, in living cells they show great mobility and plasticity, in some cells forming long, moving chains while in others being fixed in position near sites of high ATP consumption; e.g. in cardiac muscle they are packed between the myofibrils while in a sperm they are tightly wrapped around the flagellum. Mammalian hepatocytes each contain 1000–2000 mitochondria, roughly 20% of the cell volume. A mitochondrion has two functionally distinct membrane systems, the outer one completely surrounding the whole organelle and the inner one being infolded into **cristae**. These membrane systems define two compartments: the mitochondrial matrix and the intermembrane space. The matrix contains enzymes for the oxidation of pyruvate and fatty acids and for the tricarboxylic-acid cycle; it also contains the mitochondrial DNA and the enzymes and structures necessary for expression of the mitochondrial genes. The inner membrane contains the enzymes of the respiratory chain, ATP synthetase, and specific transport proteins. The intermembrane space contains a

number of kinases. The outer membrane, which is permeable to molecules of up to 10 kDa, contains monoamine oxidase, cytochrome *b₅*, a number of transferases, and a fatty-acid elongation system. The mitochondrion was formerly known as a **chondriosome** and by numerous other names. *See also* **cercidosome**. —**mitochondrial** *adj.*

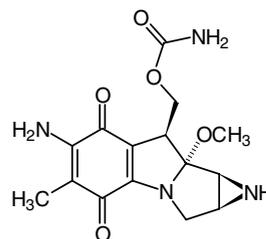

mitochrome a chromoprotein, or mixture of chromoproteins, released from mitochondria *in vitro* after ageing or other degradative processes. They are hemoproteins of ~ 105 kDa, with 1 atom of Fe per molecule, and are thought to inhibit *in vitro* oxidative phosphorylation.

mitogen any substance or agent that induces or stimulates **mitosis**. —**mitogenic** or **mitogenetic** *adj.*

mitogenic protein *abbr.*: MP; *an alternative name for interleukin 1*.

mitogillin EC 3.1.27.—; *other names*: allergen I/A; IgE-binding ribotoxin; a purine-specific ribonuclease that attacks 28S rRNA. The protein is a powerful allergen, an inhibitor of eukaryotic protein synthesis, and has anti-tumour activity. Its action is similar to **restrictocin** and ribonuclease U2.

mitomycin C a 334 Da antibiotic and the principal member of the aziridine antibiotics (mitomycins) produced by *Streptomyces caespitosus*. It is toxic to bacteria and mammalian cells and possesses antineoplastic activity. When administered, mitomycin C undergoes intramolecular rearrangement and reduction within cells to form a bifunctional alkylating agent that irreversibly cross-links the two strands of duplex DNA molecules, thereby inhibiting DNA synthesis.

mitoplast a structure consisting of the inner membrane and the matrix of a **mitochondrion**. It is formed by removing the outer membrane and the intermembrane material by treatment of a mitochondrion with nonionic detergents under defined conditions.

mitoribosome any of the **ribosomes** found in mitochondria. They resemble those of bacteria and are sensitive to chloramphenicol.

mitosis or **karyokinesis** the division of a eukaryotic cell nucleus to produce two daughter nuclei that contain identical numbers of chromosomes and that are identical genetically to the parent nucleus except where crossing over or mutation has occurred. It is divided into five main stages: **prophase**, **prometaphase**, **metaphase**, **anaphase**, and **telophase**. Mitosis is normally accompanied by **cytokinesis** leading to division of the cell. *Compare* **meiosis**. —**mitotic** *adj.*

mitotic coefficient or **mitotic index** the proportion of cells in a population that are in **mitosis** at a given time.

mitotic recombination or **somatic crossing over** crossing over between homologous chromosomes during mitotic division of a diploid somatic cell. The result of such a recombination will be imperceptible if the cell is homozygous at the loci exchanged but may produce a marked effect if the dividing cell is heterozygous at these loci. *See also* **Holliday junction recombination**.

mitotic spindle *see* **spindle**.

mixed acid fermentation a particular mode of bacterial fermentation of glucose that is characteristic of many members of the Enterobacteriaceae, e.g. *Escherichia*, *Salmonella*, and *Shigella*. It yields, as principal products, acetic, formic, lactic, and succinic acids, in varying proportions according to the organism and growth conditions.

mixed anhydride any **acid anhydride** formed between two different acids.

mixed-bed deionizer an apparatus for removing electrolytes from impure water (or an aqueous solution) and containing an intimate

mixture of anion- and cation-exchange resins. It is frequently fitted with a device for measuring the electrolytic conductivity of the effluent.

mixed-bed resin a common but imprecise term for an intimate mixture of anion- and cation-exchange resins as used in a mixed-bed deionizer.

mixed-function oxidase or **mixed-function oxygenase** an older term for monooxygenase.

mixed indicator 1 a mixture, in definite proportions, of two acid–base indicators, or of an indicator and a dye, chosen so as to produce a sharp colour change over a narrow range of pH values. **2** a mixture, in definite proportions, of two or more acid–base indicators chosen so as to produce a series of colour changes over an extended range of pH values.

mixed inhibition or **mixed-type inhibition** inhibition of the activity of an enzyme that yields complex kinetic data that cannot be clearly categorized as either competitive or non-competitive. This can result e.g. when the enzyme–substrate–inhibitor complex undergoes the catalytic process slowly, or where binding of the inhibitor changes both k_{cat} and K_m .

mixed inhibitor or **mixed-type inhibitor** any inhibitor that produces mixed inhibition of the activity of an enzyme.

mixed labelled describing a specifically isotopically labelled compound that has more than one type of modified atom, e.g. $[^{13}C]H_3-CH_2[^{18}O]H$.

mixed-lymphocyte reaction or **mixed-leukocyte reaction** the reaction that occurs when leukocytes from two genetically differing individuals are cultured together. Small lymphocytes are transformed into immature blast cells, with synthesis of DNA, to an extent that is related to the degree of disparity between the histocompatibility antigens of the cell donors. This reaction forms the basis of a test for the acceptability of an allograft.

mixed triacylglycerol or (formerly) **mixed triglyceride** any triacylglycerol that contains three types of acyl residue.

mixed-type inhibition an alternative term for mixed inhibition.

mixed-type inhibitor an alternative term for mixed inhibitor.

mixed valency describes coordination compounds and clusters in which a metal is present in more than one level of oxidation. In metal clusters the valence electrons are often completely delocalized, allowing efficient electron-transfer processes.

mixotropic series a series of solvents arranged on the basis of their ability to form hydrogen bonds. It is based on the extent to which two given solvents in this series will mix; near neighbours in the series are isopartitive.

mixture (in chemistry) homogeneous or heterogeneous material in any physical state that consists of two or more chemical components that have no firm chemical bonding between them and that are physically separable.

MK *abbr.* for menaquinone.

mks system or **MKS system** *abbr.* for metre–kilogram–second system (of electrical units).

mL or **ml** *symbol* for millilitre.

MLD *abbr.* for minimum lethal dose.

M line *see* sarcomere.

MluI a type 2 restriction endonuclease; recognition sequence: A↑CGCGT.

mM or **mM** *symbol* for millimolar.

M **macroglobulin** a paraprotein of IgM type that is produced by individuals with Waldenström's macroglobulinemia.

MMDB *abbr.* for molecular modelling database; *see* structure database.

mmHg *symbol* for the conventional millimetre of mercury.

MMLV *abbr.* for Moloney murine leukemia virus; a virus that encodes a reverse transcriptase with high processivity used in the generation of cDNA.

mmol *symbol* for millimole.

MMP *abbr.* for matrix metalloproteinase.

MMPI *abbr.* for matrix metalloproteinase inhibitor.

MMTV *abbr.* for mouse mammary tumour virus.

Mn *symbol* for manganese.

mnemonic enzyme mechanism or **mnemonic enzyme mechanism** an enzyme mechanism proposed to explain cooperativity to-

wards substrate shown by monomeric enzymes with only one substrate-binding site. In this mechanism free enzyme is considered to exist in two conformations, I and II, that are only relatively slowly interconvertible and that differ in their substrate-binding affinities; the binding of substrate induces a change of the enzyme to a third conformation, III, which reverts to conformation I when product is released. The behaviour of the system depends on the rate of interconversion of I and II and on the relative rates at which these forms can bind substrate. If the binding by I is more rapid than that by II, the system will show positive cooperativity, i.e. the enzyme has 'remembered' the catalytically more effective conformation; if the converse, the system will show negative cooperativity.

MNSs system one of the blood-group systems of humans, in which the antigens are the **glycophorins** of the erythrocytes. It was the second human-blood-group system to be discovered, the first being the ABH system (*see* **ABH antigens**). The M and N antigenic sites are poorly immunogenic and antibodies to M and N antigens do not normally occur in the blood. The determinants are located at the N terminus of glycophorins A and B (GPA and GPB); polymorphism between M and N antigens on GPA is attributed to amino-acid substitutions at residues 1 (Ser/Leu) and 5 (Gly/Glu), but the N-terminal Ser¹ and Leu¹ are the primary determinants for the M and N antigens respectively. GPB carries 'N' (N-like activity), S/s, and U blood-group antigens; 'N' activity resides at the N terminus of GPB, the sequences of GPA and GPB between residues 1 and 26 being identical; the S/s antigenic determinants arise from Met/Thr polymorphism at residue 29 of GPB; and the U antigen, present in all Caucasians and most Blacks, resides between residues 33 and 39.

Mo *symbol* for molybdenum.

mob the genetic notation for genes involved in the mobilization of a plasmid from cell to cell.

mobile element an alternative term for transposon.

mobile phase the phase that moves in a chromatographic system; it can include the portion of the starting sample present in this phase at any given time.

mobility 1 the property of being mobile. **2** *see* electrophoretic mobility. **mobilization** or **mobilisation 1** the act or process of mobilizing. **2** the process by which a conjugative plasmid brings about the transfer from one cell to another of DNA to which it is not stably and covalently linked.

mobilize or **mobilise** to bring (resources or reserves) into use for a particular purpose, e.g. to mobilize fat by lipolysis or glycogen by glycogenolysis.

mobilizing plasmid or **mobilising plasmid** an alternative name for conjugative plasmid.

Möbius strip or **Moebius strip** any one-sided continuous surface with a single bounding curve made by twisting a ribbon through 180° and joining the ends together. When divided lengthwise it forms another Möbius strip of double the length, and is a model for the replicative behaviour of a circular chromosome that contains a single twist. [After its inventor, August Ferdinand Möbius (1790–1868), German mathematician.]

Mo cell a relatively small cell, containing round, osmophilic granules, that is believed to produce motilin. Mo cells occur in the upper small intestine of humans, mainly in the crypts; they are sparse in the lower small intestine.

MoCo *abbr.* for molybdenum cofactor.

modal class (in a statistical distribution) the class that contains the mode (def. 2).

mode 1 any particular way or manner of existing or of doing something. **2** (in a statistical distribution) the value of the variable occurring with greatest frequency. **3** any of the several wave frequencies that an oscillator can generate, or to which a resonator can be tuned to respond. —**modal adj.**; **modality n.**

modeccin a 57 kDa lectin present in the turnip-like root of the southern African plant, *Modecca digitata*. It is highly toxic to animals, its prime action being on the liver, and to animal cells in culture. It consists of two polypeptide subunits in disulfide linkage, the A (smaller) subunit being biologically indistinguishable from the A subunits of ricin and abrin. *See also* ribosome-inactivating protein.

model 1 a three-dimensional representation of an object, structure, etc., sized to be conveniently seen, handled, and studied. **2** a con-

ceptual representation of a particular phenomenon, system, or set of experimental observations as an aid to understanding and as an object for test or for further experimentation. **3** an animal that, often as a result of mutation, mimics a pathological condition and can be used to study the pathogenesis of the condition. *See also transgenic.* **4** a mathematical representation of a particular phenomenon, system, or set of experimental observations as an aid to calculation and prediction. **5** to construct or create a **model** (def. 1, 2, 3). —**modelled** or (*sometimes US*) **modeled** *adj.*; —**modelling** or (*sometimes US*) **modeling** *n.*

model organism an organism used in research to exemplify its type and to represent more complex organisms in which similar phenomena are thought to or do occur. Examples include the bacterium *Escherichia coli*, the yeast *Saccharomyces cerevisiae*, the worm *Caenorhabditis elegans*, the fruit fly *Drosophila melanogaster*, the flowering plant *Arabidopsis thaliana*, and the rodent *Mus musculus*.

model system any biological or biochemical system that is used for study because it is considered to be representative of one or more other (often more complex) systems in which similar phenomena occur or are believed to occur.

moderator or **modulator** any substance that changes the rate of an enzymic or other reaction, either positively or negatively.

modification 1 (*in biochemistry*) *see* **covalent modification.** **2** (*in genetics*) any nonheritable change in the phenotype of an organism in response to variation of its environment; it includes **host-controlled modification.** *Compare* **mutation.**

modification enzyme any enzyme that effects **covalent modification**, and specifically the DNA methylase component of the **restriction-modification system.** Such methylases are conventionally named in the same way as **restriction endonucleases** with a prefix 'M' and in this dictionary they are listed, where appropriate, under the corresponding nuclease (e.g. *M.AluI* appears under *AluI*).

modification gene *see* **restriction-modification system.**

modification methylase a common name for any of the enzymes that methylate specific sites on a DNA molecule.

modification-restriction system an alternative name for **restriction-modification system.**

modified LDL a low-density lipoprotein (LDL) particle that has been modified *in vitro* by acetylation, treatment with malondialdehyde, cigarette smoke, or oxidation by copper. Similar changes *in vivo* have been implicated in atherogenesis. Such particles bind to a modified LDL (or scavenger) receptor on macrophages and are internalized, thereby transforming the macrophages into foam cells.

modifier an alternative term for **effector.**

modifier gene or **modifying gene** any gene that affects the phenotypic expression of a gene or genes at other loci.

modify 1 to alter the structure, character, activity, etc. of (something). **2** to convert a chemical compound into an analogue, especially by substitution. *See also* **modification.**

modular primer an unligated tandem arrangement of **primers** (usually two or three) used for the **polymerase chain reaction** and related experiments.

modulating codon any codon that controls the frequency with which a **cistron** or cistrons are transcribed.

modulation 1 adjustment or regulation of the degree or activity of something. **2** regulation of the frequency with which a **cistron** or cistrons is transcribed. **3** control of the activity of a regulatory enzyme by an effector. **4** (*in physics*) the process of changing the amplitude, frequency, or phase of a wave by combination with another wave.

modulator 1 something that modulates or brings about modulation. **2** any molecule that acts as an **effector.** **3** (*in pharmacology*) a ligand that increases or decreases the action of an agonist by combining with a distinct (allosteric) site on the receptor macromolecule. **4** an alternative name for **moderator.**

modulator protein an alternative name for **calmodulin.**

module a standardized or self-contained part or unit of construction, especially one that can be used in alternative combinations with others; e.g. one of a set of such assemblies of electronic components that comprise a larger piece of equipment or one of a number of autonomous protein folding units (or building blocks) that

are often used to confer a variety of complex functions on a parent protein, either by multiple combinations of the same unit or by combinations of different units to form mosaics; the spread of protein modules is believed to involve genetic shuffling mechanisms (e.g. a **kringle** or SH3 domain). —**modular** *adj.*

MODY *abbr.* for maturity-onset diabetes of the young.

moesin *abbr.* for membrane-organizing extension spike protein; a protein, isolated from bovine uteri, containing a domain similar to one in **ezrin**, band 4.1 and related proteins. Moesin occurs in many cell types and tissues, and is involved in connections of major cytoskeletal structures to the plasma membrane.

Moffitt-Yang equation or **Moffitt equation** a phenomenological equation, related to the **Drude equation**, that describes the anomalous variation of optical rotatory dispersion with wavelength shown by polypeptides containing helical sections. It is used to provide an estimate of the alpha-helical content of polypeptides and proteins. If λ is the wavelength of observation and $[m']_{\lambda}$ is the reduced **mean residue rotation** at that wavelength,

$$[m']_{\lambda} = \{a_0\lambda_0^2/(\lambda^2 - \lambda_0^2)\} + \{b_0\lambda_0^4/(\lambda^2 - \lambda_0^2)^2\},$$

where a_0 , b_0 , and λ_0 are empirical constants; a_0 is a function of contributions to the optical rotation from both the helix and the residue side-chains, as well as from the solvent, and b_0 and λ_0 are related principally to the amount of helical structure in the molecule. A value of λ_0 is chosen to give the best straight line when $[m'](\lambda^2 - \lambda_0^2)$ is plotted against $1/(\lambda^2 - \lambda_0^2)$, a good fit usually being obtained if $\lambda_0 = 212$ nm when $\lambda = 350$ – 600 nm. The slope of this line, $b_0\lambda_0^4$, gives a value of b_0 , whence, by reference to the values found for non-helical and fully helical synthetic polypeptides an estimate may be made of the alpha-helical content of a polypeptide or protein under investigation. [After W. Moffitt and Jen Tsi Yang (1922–).]

Mohr pipette a cylindrical pipette calibrated for delivery from the zero mark to a particular chosen graduation mark. [After Carl Friedrich Mohr (1806–1879), German chemist.]

Mohr's salt ammonium ferrous sulfate; di-ammonium iron(II) sulfate hexahydrate; $(\text{NH}_4)_2\text{SO}_4 \cdot \text{FeSO}_4 \cdot 6\text{H}_2\text{O}$.

m.o.i. *abbr.* for multiplicity of infection; the ratio of viral particles to organisms or cells exposed to infection.

moiety either of two, usually distinctive, component parts of a complex molecule; e.g. the steroid and saccharide moieties of a cardiac glycoside.

mol *symbol* for mole.

mol. *abbr.* for 1 molecular. **2** molecule.

μmol *symbol* for micromole.

molar 1 denoting the concentration of a solute (or a solution as a whole) expressed as the amount of substance of the solute divided by the mass of solvent. It is measured in moles per kilogram. **2** denoting an amount-of-substance **concentration** measured in such terms. *Compare* **molar.**

molarity *symbol:* *m* or *b*; a measure of concentration expressed as the number of moles (of a specified solute) per kilogram of solvent. Molarity is independent of temperature. *See also* **molal.**

molar 1 denoting an extensive physical quantity that is measured per mole (of a specified substance). It is usually denoted by the subscript *m* in the symbol; e.g. **molar volume** is the volume of one mole of a substance, and the symbol is V_m . *Compare* **specific.** **2** denoting an intensive physical quantity that is measured per mole (of a specified substance); i.e. divided by concentration. Use of the term **molar** in this sense is no longer recommended, except in the terms **molar absorption coefficient** and **molar conductivity.** **3** denoting the concentration of a solute (or a solution as a whole), expressed as the amount of substance of the solute divided by the mass of the solution. The recommended units are moles per litre but the convenient symbols *M* and *m* are frequently used. *Compare* **molal.**

molar absorbancy index a former name for **molar absorption coefficient.**

molar absorption coefficient either the **molar decadic absorption coefficient** (*symbol:* ϵ) or the **molar Napierian absorption coefficient** (*symbol:* κ); these are, respectively, the decadic **absorbance** or the Napierian absorbance of a substance, or of a solute in solution, (at a specified wavelength (or frequency) and temperature) divided by the optical path length (in cm) of the medium and by the amount-

of-substance concentration of the substance; i.e. the decadic or Napierian absorption coefficients of a medium whose concentration is expressed in moles per litre. *Former names:* molar absorptivity; molar extinction coefficient; molar extinction coefficient. *See also* **absorption coefficient**.

molar absorptivity a former name for **molar absorption coefficient**.

molar activity an **activity** (def. 1) of a substance or material divided by its amount of substance (in moles). *Compare* **specific activity**.

molar catalytic activity the **catalytic activity** of an enzyme, under specified conditions, divided by the amount of substance (in moles), either of enzyme catalytic centres or of multi-centre molecules; in the latter case it is important to specify whether the measurements refer to catalytic centres or to molecules. It may be expressed in katal per mole of enzyme. If the conditions specified are such that the enzyme is saturated with substrate, the expression (which then replaces the obsolete term turnover number) will be numerically equal to the **catalytic constant**, in s^{-1} , for decomposition of the enzyme-substrate complex into enzyme and products, although its interpretation may be complex. *Compare* **molar enzymic activity**, **specific catalytic activity**.

molar concentration an old but now incorrect term for **amount-of-substance concentration** measured in moles per litre. *See* **molar** (def. 2).

molar conductivity *symbol:* Λ ; the **electrolytic conductivity** of a (specified) electrolyte divided by its amount-of-substance concentration. The SI derived unit is the $\text{S m}^2 \text{mol}^{-1}$.

molar decadic absorption coefficient *symbol:* ϵ ; *see* **molar absorption coefficient**.

molar ellipticity or (formerly) **molecular ellipticity** *symbol:* $[\Theta]$; an expression of circular dichroism, $\Delta\epsilon$, at a specified wavelength, λ . It is given by the relation: $[\Theta]_{\lambda} = 3299 \Delta\epsilon_{\lambda}$.

molar enzymic activity (obsolete) the phenomenological coefficient relating the **enzymic activity** (under specified conditions) to the molar amount of enzyme substance; it is expressed in katal per mole of enzyme. It has now been superseded by **molar catalytic activity**.

molar extinction coefficient a former name for **molar absorption coefficient**.

molarity an older (still widely used) term for **amount-of-substance concentration** expressed in mol dm^{-3} or mol L^{-1} . *See* **concentration** (def. 1b), **molar** (def. 3).

molar mass the mass of a substance divided by its **amount of substance**; it is commonly expressed in grams (sometimes kilograms) per mole. *Compare* **molecular mass**, **relative molecular mass**.

molar Napierian absorption coefficient *symbol:* κ ; *see* **molar absorption coefficient**.

molar optical rotation *symbol:* $[m]$ or $[M]$; the observed optical rotation, α_{obs} , of a substance, or of a solute in solution, (at a specified wavelength (or frequency) and temperature) divided by the optical path length (in dm), l , of the medium and by its amount-of-substance concentration (in mol dm^{-3}), c . It is given by:

$$[m] = \alpha_{\text{obs}}/cl = [\alpha]_{\lambda}^{\theta} M_r/100$$

in $\text{deg dm}^2 \text{g}^{-1}$, where $[\alpha]_{\lambda}^{\theta}$ is the **specific optical rotation**.

molar optical rotatory power *symbol:* α_m ; it is given by the relation $\alpha_m = \alpha/cl$ in $\text{rad m}^2 \text{mol}^{-1}$, where α is the observed rotation in radians, c is the amount-of-substance concentration in mol dm^{-3} , and l is the optical path length of the sample in m. *See also* **specific optical rotatory power**.

molar volume *symbol:* V_m ; the volume occupied by a substance, under specified conditions of temperature and pressure, divided by its **amount of substance**; it is commonly expressed in litres per mole.

mold the US spelling of **mould**.

mole *symbol:* mol; the SI base unit of **amount of substance**, defined as the amount of substance of a system that contains as many elementary entities as there are atoms in 0.012 kilogram of carbon-12; the elementary entities must be specified and may be atoms, molecules, ions, electrons, other particles, or specified groups of such particles. One mole of a compound has a mass equal to its **relative molecular mass** in grams.

molecular 1 of or pertaining to a molecule or molecules. 2 consisting of or existing as molecules; (especially of certain gaseous ele-

ments) present or reacting as intact molecules rather than as atoms, ions, etc., e.g. molecular oxygen (i.e. dioxygen). 3 of dimensions comparable to those of molecules. 4 (*in physical chemistry*) an obsolete term meaning divided by molecular weight or expressed per gram-molecule; **molar** now used. 5 considered in terms of or at the level of molecules, or in terms of chemical substances or structures and their interconversions; e.g. molecular biology, molecular medicine.

+molecular *comb. form* indicating the **molecularity** of a chemical reaction (when qualified by a multiplicative prefix), e.g. unimolecular, bimolecular, termolecular.

molecular beacon or **molecular platform** a protein that contains a variety of domains for specific proteins and serves as a platform for the assembly of specific proteins that mediate a particular function. *See* **REST**.

molecular biology the science that studies the chemical and physical basis of biological specificity and variation, especially with regard to the structure, replication, and expression of genes, and to the structure, interaction, and physiological function of gene products. —**molecular biologist** *n*.

molecular chaperone *see* **chaperone**.

molecular clock the principle that the relationship between evolutionary distance as determined from macromolecular sequences and time is approximately linear, a concept consistent with the neutral theory of evolution in the presence of more or less constant functional constraints.

molecular cloning or **DNA cloning** the isolation in a bacterial cell of a fragment of any heterologous DNA in covalent linkage with a replicon (plasmid, phage, etc.) in order to obtain a homogeneous population (i.e. clone) of DNA molecules from the progeny of such a cell. The DNA to be cloned may be a fragment of genomic DNA obtained by restriction endonuclease digestion, or a complementary DNA (cDNA). The foreign DNA is inserted into the **cloning vector**, which has been cleaved with a restriction enzyme; the gaps between vector and insert DNA are sealed with DNA ligase. In cloning using plasmid vectors, plasmids are then reintroduced into host cells by **transformation**; markers on the cloning vector allow selection of plasmid-containing cells and identification of those cells that contain recombinant plasmids (rather than 'empty' vectors). To identify clones containing particular sequences, DNA from individual colonies may be screened with a labelled DNA probe by **colony hybridization**. In cloning using bacteriophage vectors, the ligated insert and vector are packaged into phage capsids *in vitro*, and then these are used to infect host bacteria.

molecular disease any disease caused by an abnormality in a single protein, usually an enzyme. This may have an abnormal structure that makes it functionally less efficient or harmful to the organism, or it may have a normal structure but be present in reduced amount. Examples are the many inborn errors of metabolism and **sickle-cell anemia**. Overproduction of proteins, e.g. of oncogene products, may also lead to a pathological situation.

molecular distillation distillation at very low pressures (at or below 1.3 N m^{-2}) when the mean free path of the molecules is of the same order as the distance between the surface of the liquid being distilled and the distillate; the molecules can therefore travel rapidly from the liquid to the distillate with relatively few collisions, and with a reduced risk of thermal denaturation or decomposition. The technique is useful in the separation and purification of fat-soluble vitamins and other natural products.

molecular drive or **concerted evolution** a theory to explain the observed greater homogeneity of members of a multigene family within a species compared with their homologous counterparts in a sister species. It holds that unequal crossing over and other mechanisms of molecular turnover between homologous chromosomes spread a particular variant of a gene in a multigene family from one chromosome to the next. The variant gene is spread through the population by sexual reproduction until it reaches fixation.

molecular dynamics the study of the relative intramolecular differences in the motions of the components of (macro)molecules.

molecular ellipticity a former term for **molar ellipticity**.

molecular endocrinology endocrinology at the molecular level.

molecular entity any chemically or isotopically distinct atom, mol-

ecule, ion, ion pair, radical, radical ion, complex, conformer, etc., capable of existence as a separately distinguishable entity.

molecular enzymology (*sometimes*) the aspects of enzymology concerned with kinetics and mechanisms.

molecular evolution the process whereby changes in DNA or RNA accumulate over time via a range of different mechanisms, giving rise to changes in, for example, genes, gene products, gene expression, or the frequency of genes within populations.

molecular exclusion chromatography a *less common name* for gel-permeation chromatography.

molecular extinction coefficient a former name for molar absorption coefficient.

molecular formula a chemical formula giving the kinds and number of atoms in one molecule of a specified substance.

molecular fragmentography an alternative (*less satisfactory*) name for selected-ion monitoring.

molecular genetics the branch of genetics that attempts to describe genetic events in molecular terms.

molecular graphics *functioning as sing.* the use of computer programs for visualizing (macro)molecules, refining structures and molecular design, protein engineering, etc. Suites of programs that are commonly used include Insight, Ribbons, Midas, and O.

molecular hybridization an alternative name for hybridization analysis.

molecular ion any ion produced, especially in a mass spectrometer, when a molecule loses or gains an electron, forming a molecular cation or molecular anion, respectively.

molecularity the number of molecular entities involved in a simple, one-step, chemical reaction (it is not used to describe an overall reaction with more than one step). In the two-step reaction: $A + B \rightarrow C \rightarrow D$, the molecularity of the first step is two, i.e. it is bimolecular, and the molecularity of the second step is one, i.e. it is unimolecular.

molecular mass the mass of one molecule of a specified substance expressed in (unified) atomic mass units or daltons. *Compare relative molecular mass, molecular weight.*

molecular matchmaker any of a class of proteins, also called matchmaker proteins, that cause a conformational change in one or both components of a DNA–protein binding pair to promote formation of a metastable DNA–protein complex. ATP hydrolysis occurs in the process. Such matchmaking is used extensively in repair, replication, and transcription of DNA.

molecular medicine (*sometimes*) the branch of medicine concerned with the biochemical mechanisms of disease processes and therapy.

molecular mimicry 1 in the context of ligand receptor binding (*see ligand (def. 6)*) a molecule, unrelated to the ligand that by accident binds to the receptor. **2** in the etiology of autoimmune diseases, the hypothesis that molecules from a microorganism mimic those in an animal host, leading to activation of self-reactive lymphocytes.

molecular motor a protein or protein complex that generates force upon hydrolysis of ATP. Such motors include **myosins**, **kinesins**, **dyneins**, and **DNA helicases**.

molecular orbital a wave equation for one electron describing its movement in the effective field provided by the nuclei and all other electrons of a molecular entity of more than one atom.

molecular pathology the use of techniques of molecular biology to enhance the understanding, diagnosis, and therapy of disease (mainly with respect to humans).

molecular pharmacology the use of techniques of molecular biology to enhance the understanding of the mechanism of action of existing drugs, and with the help of molecular graphics to predict the structure of novel drugs, especially compounds that might bind to proteins of known structure.

molecular pK any one of the **pK** values of an acid with two or more dissociations. *Compare group pK, titration pK.*

molecular recognition the specific **recognition** of one molecule by another; it often includes **chiral recognition**.

molecular ruler 1 any rigid oligoproline crosslinking reagent of defined length. Such reagents are useful in probing the structures of biological macromolecules in solution. **2** any molecule that regulates length, e.g. **nebulin**.

molecular sieve any of a class of substances or materials, whether naturally occurring or artificial, that contain pores of molecular dimensions and of a closely defined range of diameters. They are useful for the separation of substances within a particular range of molecular dimensions on the basis of selective exclusion.

molecular-sieve chromatography any form of chromatography in which a separation is based mainly upon differences in molecular size and/or shape of the substances being separated. It includes **gel-permeation chromatography** and separations using **zeolites**.

molecular-sieve electrophoresis (*sometimes*) an alternative term for polyacrylamide gel electrophoresis.

molecular switch a protein that can change from an active to an inactive form by altering its conformation as a result of binding to a specific ligand or of chemical modification.

molecular tinkering the evolutionary process of transforming pre-existing genes or parts of genes to produce new roles or functions, or of combining molecular systems to give new, often more complex, systems. For example, in mammals, lysozyme, an ancient hydrolytic enzyme that destroys bacterial cell walls, has been recruited as the milk protein α -lactalbumin. Similarly, in birds and reptiles, the ancestral ornithine-urea cycle enzyme argininosuccinate lyase has been recruited as a water-soluble eye-lens structural protein, δ -crystallin.

molecular weight *abbr.*: mol. wt. or M.W.; a former name for relative molecular mass.

molecular weight cut-off or **cut-off** a jargon term for the nominal maximal value of the relative molecular mass of a macrosolute that can pass through an ultrafiltration membrane of a particular grade.

molecular weight marker or **molecular weight standard** a jargon term for any soluble polymer of accurately known relative molecular mass that serves as a reference in estimations of M_r values of polymers by techniques such as gel permeation chromatography or gel electrophoresis. Generally a set of such substances, covering a range of M_r values, is used.

molecule a structural unit of matter consisting of one or more atoms; the smallest discrete part of a specified element or compound that retains its chemical identity and exhibits all its chemical properties.

mole fraction an alternative name for amount-of-substance fraction. *See concentration.*

mole percent the quantity mole fraction multiplied by 10^{-2} ; usage no longer recommended.

Molisch test a qualitative test for free or combined aldohexoses. It depends on the formation of a purple colour when the furfural derivatives, formed when aldohexoses are heated with strong acids (e.g. H_2SO_4), react with sulfonated 1-naphthol. [After Hans Molisch (1856–1937), Austrian chemist.]

mollicute *see mycoplasma.*

Molscrip a computer program, written by Per Kraulis, for displaying molecular 3D structures such as proteins.

mol the US spelling of **moult**.

moulting hormone the US spelling of moulting hormone (i.e. **ecdysterone**).

mol. wt. *abbr.* for molecular weight (alternative to M.W.).

molybdate 1 the bivalent anion, MoO_4^{2-} , derived from molybdic acid. **2** any salt of molybdic acid.

molybdenum *symbol*: Mo; a metallic transition element of group 6 of the (IUPAC) **periodic table**; atomic number 42; relative atomic mass 95.94. It consists of a mixture of eight stable nuclides of which the commonest is that of mass number 98. It forms molybdates (molybdenum(VI)) and can also exist in various lower oxidation states. Molybdenum is of low abundance in the Earth's crust and is an essential trace component of living material, where it participates in numerous redox reactions. It is a constituent of component I (or molybdoferredoxin) of the **nitrogenase** (EC 1.18.6.1) complex from legume nodule bacteria (bacteroids), which converts nitrogen into ammonia. There are many artificial radionuclides of molybdenum, of which the most widely used is molybdenum-99.

molybdenum cofactor a cofactor of **molybdoenzymes** of human cells. It consists of a molybdenum atom complexed by vicinal sulfhydryl groups on a unique pterin species called **molybdopterin**. In some bacteria it is present as a dinucleotide. Synthesis of the cofac-

tor starts with GTP and proceeds by a pathway independent from that for folate or bipterin synthesis. It has been well studied in *E. coli* but homologous genes have been found in the human genome.

molybdenum cofactor deficiency a severe autosomal disease of humans in which activity of the three **molybdoenzymes** is lacking and leads to accumulation and increased excretion of sulfite, thiosulfate, *S*-sulfocysteine, taurine, xanthine, and hypoxanthine. Clinically the presentation is very similar to that of sulfite oxidase deficiency. It is caused by a defect in the synthesis of **molybdenum cofactor**.

molybdo+ *comb. form* denoting containing molybdenum, e.g. molybdoprotein.

molybdoenzyme any enzyme that contains tightly bound **molybdenum cofactor**. Examples from human cells are aldehyde oxidase (EC 1.2.3.1), sulfite oxidase (EC 1.8.2.1), and xanthine dehydrogenase (EC 1.17.1.4). A very rare combined deficiency of these three enzymes presents as xanthinuria.

molybdoferredoxin *an alternative name for* component I of **nitrogenase**.

molybdophosphoric acid or **phosphomolybdic acid** a heteropolyacid of approximate formula $24\text{MoO}_3 \cdot \text{P}_2\text{O}_5 \cdot x\text{H}_2\text{O}$, where x is approximately 50. It is useful in reagents for alkaloids, xanthine, uric acid, creatinine, etc.

molybdopterin or **pyranopterin** a pterin derivative that binds molybdenum or tungsten in enzymes. *See* **molybdenum cofactor**.

mon+ *a variant form of* **mono+** (sometimes before a vowel).

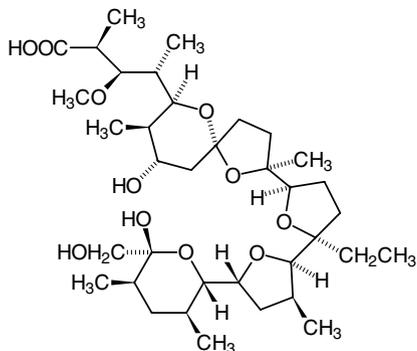

Mon *symbol for* the montanoyl group.

monactin *see* **nonactin**.

monatomic or **monoatomic** (of a molecular entity) composed of only one atom.

monellin an ~11 kDa protein consisting of two polypeptide chains, linked non-covalently, isolated from the fresh fruits of the African shrub, *Dioscoreophyllum cumminsii*, known as serendipity berry. It is intensely sweet-tasting, being 3000 times sweeter than sucrose on a mass basis, and has sequence similarities with **thaumatin**.

monensin a 671 Da, open-chain macrotetrolide-like antibiotic, with many chiral centres, isolated from *Streptomyces cinnamonensis*. It forms stable complexes with monovalent cations, especially with Na^+ , and exhibits high Na^+/K^+ selectivity. These complexes are soluble in organic solvents and thus monensin can act as an **ionophore** for monovalent cations. It is used as a digestion-modifying feed additive in ruminants.

Monera the kingdom containing all prokaryotic organisms (i.e. bacteria and cyanobacteria) in the five-kingdom system of classification. — **moneran** *adj.*, *n*.

mongolism *an older name for* **Down's syndrome**.

monitor **1** any instrument or device for checking, controlling, measuring, or keeping a record of some varying biological activity or chemical or physical property, e.g. absorbance, (radio)activity, concentration, pH, respiration. **2** to serve as a monitor of (some activity or property); to use a monitor.

mono+ or (sometimes before a vowel) **mon+** *comb. form* **1** denoting one, single, onefold, once, alone; **uni+**. **2** (in adjectives describing physical attributes) homogeneous; e.g. monochromatic, monodis-

perse, monoenergetic. **3** (in generic names of chemical compounds) denoting that member of a series (a) having only one specified substituent or other chemical modification, e.g. monoacylglycerol, monoamine; or (b) comprised of only one constitutional unit, e.g. monomer, monosaccharide. **4** *informal term (in specific names of chemical compounds)* indicating or emphasizing the presence in a molecule of a single specified atom, group, or residue; e.g. monoiodotyrosine, adenosine monophosphate, monosodium dihydrogen phosphate. **5** (in adjectives describing compounds or substances) having a single function of the kind specified; e.g. monoacidic, monobasic, monodentate, monohydric. **6** (in names of processes or enzymes) concerned with or acting on, one or only one chemical group of the kind specified; e.g. monoiodination, monoesterase.

monoacidic (of a **base** (def. 1)) able to accept only one proton per molecule in solution.

monoacylglycerol or (formerly) **monoglyceride** any ester of glycerol in which any one of its hydroxyl groups has been acylated with a fatty acid, the others being non-esterified.

monoacylglycerol pathway a pathway in which diacylglycerols and triacylglycerols are formed by sequential acylation of monoacylglycerol by acyl-CoA. It is important during fat absorption since monoacylglycerol is extensively absorbed from the gut; however, it is also present in a large number of other mammalian tissues. There is little evidence for this pathway in plants.

monoamine oxidase *abbr.:* MAO; *a common name for* amine oxidase (flavin-containing), EC 1.4.3.4; an enzyme, widely distributed in animal tissues, that catalyses the oxidative deamination of primary amines by a reaction between dioxygen and $\text{R-CH}_2\text{-NH}_2$ to form R-CHO , NH_3 , and H_2O_2 . It also acts on secondary and tertiary amines. It is important in the catabolism of neuroactive amines, e.g. epinephrine, norepinephrine, serotonin (5-hydroxytryptamine), and tyramine. Mammals have two genes for MAO, both on the X chromosome and near the Norrie disease gene. MAO-A (human, 520 amino acids) contains FAD and is a transmembrane protein of the outer mitochondrial membrane in most tissues. It shares 70% sequence identity with MAO-B (527 amino acids). Deficiency of either or both can be associated with deletion of the Norrie disease gene. *See* **Norrin**.

monoamine oxidase inhibitor any compound that inhibits **monoamine oxidase** (*abbr.:* MAO) and is useful as a thymoleptic (antidepressant) drug. MAO inhibitors act by increasing the concentrations of **norepinephrine** and **serotonin**, which, because of the block on their metabolism, accumulate in the synaptic gap and exert an increased postsynaptic effect. They were discovered as a result of the euphoric side effect of the antitubercular drug **isoniazid**. There are two main groups: (1) the **cyclopropylamines**, including tranylcypromine (*trans*-phenyl-cyclopropylamine); and (2) the **propargylamines**, including pargyline (*N*-benzyl-*N*-methyl-2-propynylamine). **Harmin** and related carboline alkaloids are reversible MAO inhibitors but are not used therapeutically.

monoatomic *a variant spelling of* **monatomic**.

monobactam any of a family of *N*-sulfonated monocyclic β -lactam antibiotics produced by a range of bacterial species.

monobasic **1** (of an acid) able to yield only one hydrogen ion per molecule in solution. **2** (of a salt or ester of a polybasic acid) derived by the replacement of only one of its dissociable hydrogen atoms per molecule.

monochromatic **1** or **homochromatic** involving, possessing, or relating to a single colour; consisting of, relating to, or emitting light (or other electromagnetic radiation) of a single frequency or wavelength. **2** *an alternative term for* **monoenergetic**. *Compare* **heterochromatic** (def. 1), **polychromatic**.

monochromator a device used for producing light (or other electromagnetic radiation) of essentially one frequency or wavelength, which may be fixed or selectable.

monocistronic containing as much genetic information as is contained in a single **cistron**.

monocistronic messenger RNA any messenger RNA molecule that carries one initiation site and encodes the synthesis of one polypeptide chain. It is characteristic of eukaryotes, which do not possess **polycistronic messenger RNA**.

monoclonal 1 of, pertaining to, being, formed by, or derived from a single clone (def. 1). **2** (*sometimes*) an informal name for **monoclonal antibody**.

monoclonal antibody or (*informal*) **monoclonal** an immunoglobulin secreted by a single clone of antibody-producing cells, either *in vivo* or in culture. Such antibodies are **monospecific**; they can thus be useful as immunochemical reagents for the detection or assay of particular antigens, or used in therapy. *See also* **humanize**, **hybridoma**.

monocomponent insulin a commercial preparation of natural insulin that has been highly purified by chromatography and is thus made essentially free of proinsulin, intermediates in the conversion of proinsulin to insulin, and breakdown products of insulin, as well as any unrelated contaminants.

monocotyledon or **monocot** any flowering plant having a single cotyledon (seed leaf) in the embryo. Such plants comprise the class Monocotyledonae.

monocyclic having a single ring of atoms in the molecule.

monocyte a large leukocyte of the **mononuclear phagocyte system**, 16–22 μm in diameter (in humans), with pale-staining cytoplasm and a reniform or horseshoe-shaped nucleus. Found in bone marrow and the bloodstream, monocytes are derived from pluripotent stem cells and become macrophages when they enter the tissues.

monodisperse describing a colloidal system in which the dispersed phase consists of particles all of (nearly) the same size. —**monodispersity** *n*.

Monod-Wyman-Changeux model (for allosteric interactions) *abbr.*: MWC model; a model describing the nature of **allosteric** interactions in proteins. It requires an allosteric protein to be an oligomer, the protomers of which are associated in such a way that they all occupy equivalent positions. Each protomer has only one stereospecific binding site for each ligand. The protein can exist in either of two conformational states, the T form (**tense form**), the predominant form when unligated, and the R form (**relaxed form**); these states are in equilibrium. The affinity of the R form for ligand is higher than that of the T form. All binding sites in each state are deemed to be equivalent and to have identical dissociation constants, K_R and K_T for the R and T forms, respectively. The sigmoidal binding curve for any allosteric protein and a given ligand can be calculated from the allosteric constant, L , equal to the ratio [T form]/[R form] for the unligated states and the two dissociation constants. [After Jacques Lucien Monod (1910–76), French microbiologist and molecular biologist, Jeffries Wyman (1901–95), US biochemist, and Jean-Pierre Changeux (1936–), French biochemist.] *See also* **mnemonic enzyme mechanism**.

monoenergetic or **monochromatic** (of moving particles and sometimes also photons) all having the same kinetic energy.

monoenoic denoting any alkenyl carboxylic acid containing one carbon–carbon double bond per molecule.

monoester any simple ester; i.e. any **ester** formed by condensation of one molecular proportion of an alcohol or phenol with one of an oxoacid.

monoesterase *see* **phosphomonoesterase**.

monofunctional having only one function or one reactive chemical group.

monoglyceride a former name for **monoacylglycerol**; its use is discouraged as it does not convey the intended meaning.

monognotobiotic an alternative term for **axenic**.

monohydric or **monohydroxy** describing any chemical compound containing one hydroxyl group per molecule. It is used especially of alcohols.

moniodinated reacted with or containing only one atom of iodine per molecule.

monokine an alternative name for a **cytokine** produced by monocytes.

monolayer 1 an alternative name for **monomolecular layer**. **2** a single layer of cells grown or growing in culture.

monomer 1 any substance that can provide one or more (in number or species) of the monomeric units of an **oligomer** (def. 1) or of a **polymer** (def. 1); a molecule of such a substance. **2** a loose term for any of the component molecules (identical or non-identical) formed by the complete dissociation of a macromolecule with quaternary structure. **3** (*in molecular biology*) **a** any protein that is made up of

non-identical structural units. **b** any of the structural units formed by dissociation of an oligomeric protein, and corresponding to a **protomer** in the undissociated protein. —**monomeric** *adj.*

monomeric unit a group of atoms, derived from a molecule of a given **monomer** (def. 1), that comprises any one species of constitutional unit of a polymer.

monomolecular 1 relating to, consisting of, or involving a singular **molecular entity**. **2** (of a reaction) having a **molecularity** of one; unimolecular.

monomolecular layer or **monolayer** a layer of a substance or substances that is one molecule thick.

mononuclear 1 (of a cell) having one nucleus. **2** (of a metal-ion–ligand complex) containing a single central metal atom.

mononuclear phagocyte system a cell system in higher animals that comprises all the highly phagocytic mononuclear cells and their precursors. It includes the free macrophages, precursor cells and promonocytes of the bone marrow, monocytes of the bone marrow and the blood, and the tissue macrophages. The term is a replacement for **reticuloendothelial system**, now held to lack precision.

mononucleosis *see* **Epstein–Barr virus**.

mononucleotide any **nucleotide** (def. 1); the term is used especially as the generic name of the constitutional repeating unit of all oligonucleotides, polynucleotides, and nucleic acids. A mononucleotide consists of the (3'- or 5'-)phosphate of a single ribonucleoside or deoxyribonucleoside. The term is extended generally to include: (1) nucleoside oligophosphates, e.g. adenosine 5'-triphosphate (ATP); (2) nucleoside diphosphate sugars, e.g. uridine 5'-diphosphate glucose (UDPG); (3) nucleoside 2',3'- and 3',5'-(cyclic)phosphates, e.g. adenosine 3',5'-phosphate (cyclic AMP); (4) nucleoside phosphates derived from artificial heterocyclic bases, e.g. 5-iodo-2'-deoxycytidine 5'-triphosphate, or from ones that do not occur naturally in nucleic acids, e.g. inosine 5'-phosphate (i.e. inosinic acid; hypoxanthine riboside 5'-phosphate; IMP); and (5) certain analogous compounds such as those containing, in place of a residue of ribose or deoxyribose, a residue of ribitol, e.g. flavin mononucleotide (i.e. riboflavin 5'-phosphate; FMN), of dideoxyribose, e.g. 2',3'-dideoxyadenosine 5'-triphosphate (i.e. ddATP), or of another pentose, e.g. cytosine arabinoside 5'-triphosphate (i.e. ara-CTP). *Compare* **oligonucleotide**, **polynucleotide**.

monooxygenase any oxidoreductase enzyme that brings about the incorporation of one atom of oxygen from dioxygen into the donor, and catalyses reactions of the type:

The following are examples. (1) Lysine 2-monooxygenase; EC 1.13.12.2; it catalyses the oxidation by dioxygen of L-lysine to 5-aminopentanamide, CO_2 , and H_2O ; FAD is a coenzyme. (2) Lysine 6-monooxygenase; EC 1.13.12.10; it catalyses the oxidation by dioxygen of L-lysine to N^6 -hydroxy-L-lysine and H_2O . (3) Tryptophan 2-monooxygenase; EC 1.13.12.3; it catalyses the oxidation by dioxygen of L-tryptophan to indole-3-acetamide, CO_2 , and H_2O . (4) *myo*-Inositol oxygenase; EC 1.13.99.1; it catalyses the oxidation by dioxygen of *myo*-inositol to D-glucuronate and H_2O ; iron is a cofactor. (5) Phenol 2-monooxygenase; EC 1.14.13.7; *other name*: phenol hydroxylase; it catalyses a reaction between phenol, NADPH, and O_2 to form catechol, NADP⁺, and H_2O ; FAD is a coenzyme. It is an enzyme of bacterial aromatic substrate utilization. (6) *trans*-Cinnamate 4-monooxygenase; EC 1.14.13.11; *other names*: cinnamic acid 4-hydroxylase; cinnamate 4-hydroxylase; CA4H; it catalyses a reaction between *trans*-cinnamate, NADPH, and O_2 to form 4-hydroxycinnamate, NADP⁺, and H_2O . It is a cytochrome P450–thiolate enzyme. *See also* **monophenol monooxygenase**.

monophenol monooxygenase EC 1.14.18.1; *other names*: tyrosinase; phenolase; monophenol oxidase; cresolase. An enzyme involved in the formation of melanins and other polyphenolic pigments, etc. It catalyses a reaction between L-tyrosine, L-dopa, and O_2 to form L-dopa, dopaquinone, and H_2O ; copper is a cofactor. It has four motifs, three for the Cu site.

monophosphatidyl glycerol any [1,2-diacyl-*sn*-glycero-3-(phospho-1-*sn*-glycerol)] lipid present in chloroplasts of higher plants.

monophyletic group a group of species (or nodes in a phylogenetic tree) that share a common ancestor that is exclusive to those species (or nodes). For example, a clade is a monophyletic group.

monoploid (of cells or individuals) having a single set of chromosomes; i.e. in a polyploid series, having the fundamental **haploid** chromosome number; true haploid.

monosaccharide *the generic name of the simplest carbohydrates.* Monosaccharides cannot be hydrolysed to give smaller carbohydrates. They are polyhydric alcohols containing either (in **aldoses**) an aldehyde group or (in **ketoses**) a keto group and with from three to ten or more carbon atoms. Monosaccharides form the constitutional repeating units of oligo- and polysaccharides. The names and structures of the common aldoses (from triose to hexose) form the basis for prefixes used to describe other compounds containing a set of >CHOH groups. For structures, see illustration (note that if X = CHO and Y = CH₂OH these structures also depict the common D aldoses). An example of prefix use is the ketoheptonic acid phosphate, DAHP, **3-deoxy-D-arabino-(2)-heptulose 7-phosphate**. By extension the stereochemical relationships are applied to substituents other than OH, e.g. in **threonine**. See also **glycose** (def. 1), **heptose**, **hexose**, **pentose**, **tetrose**, **triose**.

monose *an obsolete term for monosaccharide.*

monosodium glutamate *abbr.:* MSG; the monosodium salt of L-glutamic acid, widely used as a flavouring agent for its meaty taste, and the most active component of soy sauce. Consumption by adults of more than about 3.0 g can cause **Chinese restaurant syndrome**, characterized by a feeling of tightness, facial pressure, burning sensation, and headache. The D-enantiomer does not have the

characteristic taste and up to 7.0 g can be consumed without ill effect.

monosome 1 any chromosome in a functionally diploid chromosome set that lacks a homologue. **2** a structure consisting of a single ribosome bound to a molecule of messenger RNA.

monosomic (of cells, tissues, or individuals) having one or more **monosomes** (def. 1).

monospecific (of an antibody or an antiserum) only able to react with a single specified antigen or antigenic determinant.

monoterpene any **terpene** containing or derived from two isoprene units and thus containing ten carbon atoms. Monoterpenes may be acyclic or mono- or dicyclic.

monotonic (of a mathematical function) varying in such a manner that it continuously either increases or decreases as the independent variable increases. —**monotonically** *adv.*

monotopic an integral membrane protein that crosses the membrane once. *Compare* **polytopic**.

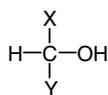

monovalent *an alternative term for univalent.*

monoxenic *see* **synxenic**.

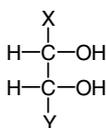

monozygotic 1 (of twins, triplets, etc.) derived from a single fertilized ovum. **2** any one of a set of monozygotic individuals. *Compare* **dizygotic**.

montanate 1 *the trivial name for* octacosanoate, CH₃—[CH₂]₂₆—COO⁻, the anion derived from montanic acid (i.e. octacosanoic acid), a saturated straight-chain higher fatty acid. **2** any mixture of free montanic acid and its anion. **3** any salt or ester of montanic acid. Montanate esters of long-chain alcohols occur in montan wax, beeswax, and some other natural waxes.

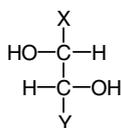

montanoyl *symbol:* Mon; *the trivial name for* octacosanoyl,

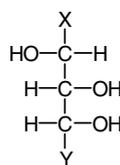

D-glycero

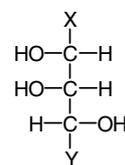

D-erythro

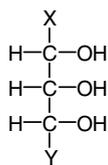

D-threo

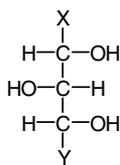

D-arabino

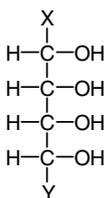

D-lyxo

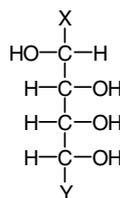

D-ribo

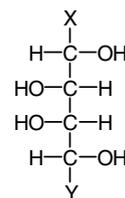

D-xylo

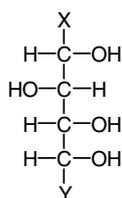

D-allo

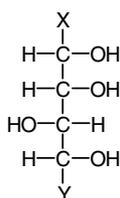

D-altro

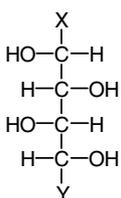

D-galacto

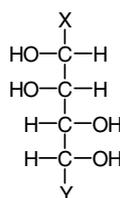

D-gluco

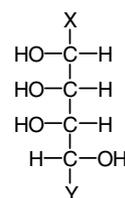

D-gulo

D-ido

D-manno

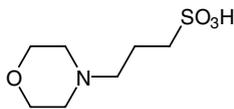

D-talo

$\text{CH}_3\text{-(CH}_2\text{)}_{26}\text{-CO-}$, the acyl group derived from montanic acid (i.e. octacosanoic acid).

Monte Carlo method a way of solving a mathematical problem by sampling methods. The procedure involves the construction of a stochastic model of the mathematical process and the performance of sampling experiments upon it. Such methods have application in molecular graphics aimed at extracting the fundamental principles of macromolecular conformation. [After the resort in Monaco famous for its casino.]

Mops or **MOPS** *abbr. for* 3-(*N*-morpholino)propanesulfonic acid; a **Good buffer substance**, $\text{p}K_{\text{a}}$ (20°C) = 7.2.

morgan a unit of genetic length along a chromosome, defined as the distance between two loci that show, on average, one crossover per meiotic event; it is equal to 100 **map units** (or Morgan's units). [After Thomas Hunt Morgan (1866–1945), US geneticist and zoologist.]

Morgan's unit *an alternative name for* map unit. *Compare* **morgan**.

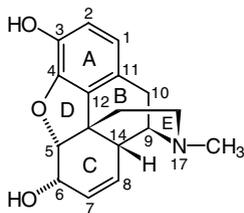

Mörner's test a qualitative test for tyrosine in which a green coloration is produced when a tyrosine-containing sample is boiled in a solution of formaldehyde in strong sulfuric acid. [After K.A.H. Mörner (1855–1917), Swedish chemist.]

morph+ *a variant form of* **morpho+** (before a vowel).

+morph *comb. form* indicating of a specified form, shape, or structure. —**+morphic** or **+morphous** *adj.*; **+morphy** *n.*

morphiceptin a tetrapeptide amide fragment of the milk protein β -casein, structure Tyr-Pro-Phe-Pro-NH₂, and the N-terminal tetrapeptide of casomorphin. It is a potent and specific agonist for μ -opiate receptors, its effects on the receptor being blocked by naloxone.

morphine 7,8-didehydro-4,5-epoxy-17-methylmorphinan-3,6-diol; an opiate and the most important opium alkaloid; it is a powerful, habit-forming narcotic analgesic. In the opium poppy, *Papaver somniferum*, it is derived from two molecules of tyrosine via (*S*)-reticuline as intermediate. Many enzymes, equivalent to those involved in its biosynthesis, have been found in mammalian liver. The diacetate ester, diacetylmorphine, is known as **diamorphine** or **heroin**. This is strongly habit forming and its manufacture, importation, and use are controlled in a number of countries. *See* **opioid receptor**.

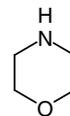

morpho+ or (before a vowel) **morph+** *comb. form* indicating form or structure.

morphogen a diffusible substance responsible for some aspect of generation of form or structure during development of an organism. Its effects are concentration-dependent. A good example is retinoic acid.

morphogenesis the ensemble of the processes of development of a part, organ, or organism. —**morphogenetic** or **morphogenic** *adj.*

morpholine tetrahydro-1,4-oxazine; a heterocyclic compound with a six-membered oxygen- and nitrogen-containing ring. A number of *N*-substituted morpholines are useful as biological buffers, e.g. **Mes**, **Mops**.

morpholine

morpholino antisense oligonucleotide a nonionic DNA analogue with an altered backbone that is resistant to nucleases. Such nucleotides can base pair with mRNA and can block gene expression and produce phenotypic effects in early development when injected into zebrafish, sea urchin, or *Xenopus* embryos.

morphology the branch of biology concerned with the outer form and inner structure of living organisms.

Morquio syndrome *another name for* mucopolysaccharidosis IV. *See* **mucopolysaccharidosis**.

MORT1 *see* **FADD**.

mortalin *other name:* 75 kDa glucose-regulated protein (*abbr.:* GRP 75); a protein that resembles **heat-shock proteins** in sequence, and may be a **chaperone**. It is a member of the heat-shock protein 70 family, which functions as a mortality marker in fibroblasts. Mortal fibroblasts contain a protein, MOT-1, uniformly distributed in the cytosol, while, in immortal fibroblasts, another form of the protein, MOT-2, is concentrated in perinuclear or juxtannuclear regions. In MOT-2, there are differences at residues 618 (Val to Met) and 624 (Arg to Gly). The cytosolic form induces cellular senescence; the perinuclear form does not.

MOS a gene family encoding serine/threonine kinases, e.g. the human and mouse protein pp39^{mos}; *v-mos* is the oncogene of the acutely transforming murine Moloney sarcoma virus (hence 'mos' from mo + s). *MOS* mRNA is detectable only in germ cells in testes and ovaries, and is implicated in meiosis; directly or indirectly it stabilizes **M-phase promoting factor** and activates **MAP kinase**. The protein has homology with Src (*see* **src**).

mosaic 1 a design or pattern on a surface, made up of numerous separate pieces of more or less the same area but differing in some characteristic, e.g. colour, shape, texture. **2** *an alternative name for* **chimera** (used especially of animals). **3** a protein comprising a number of different **modules**. —**mosaicism** *n.*

mosaic evolution within a population of organisms, the phenomenon of varying rates of evolution in different functional systems. For example, in hominid evolution, the dental, locomotor, and neurological systems have evolved at markedly different rates.

mosaic model *see* **fluid-mosaic model**.

Mössbauer spectroscopy a spectroscopic technique specific to particular atomic nuclei. The basis of the Mössbauer effect is the recoilless resonance absorption of γ -rays. For biochemical studies the relevant isotope for study is the stable isotope ⁵⁷Fe. Gamma rays are produced by a radioactive source of ⁵⁷Co, and the energy of the γ -rays emitted by the radioactive source is shifted by the Doppler shift obtained by moving the source with respect to the absorber. A more recent variation of the method uses synchrotron radiation. Parameters derived from the Mössbauer spectrum, which provide information on the chemical state of the iron are the isomer shift, the nuclear quadrupole shift and the nuclear hyperfine splitting due to interaction with unpaired electrons. [After Rudolf Mössbauer (1929–), co-winner of the Nobel Prize for Physics 1961 for his researches concerning the resonance absorption of gamma radiation.]

most parsimonious reconstruction (*in phylogeny*) for a given character in a data set, the branching order that requires the fewest mutational events to explain the contemporary sequences. *Compare* **most parsimonious tree**.

most parsimonious tree (*in phylogeny*) for all sequences in a data set, the branching order that requires the fewest evolutionary events to explain the contemporary sequences. *Compare* **most parsimonious reconstruction**.

MOT-1, MOT-2 *see* **mortalin**.

mother liquor the liquid remaining after a substance has been crystallized or precipitated from a solution.

motif 1 (*in relation to protein structure*) a locally ordered region within the core of a protein molecule, formed by 3-D interaction between two or three segments of the secondary structure (α -helix and/or β -strand) that are near one another along the polypeptide chain. The most important types are: ($\alpha\alpha$), ($\alpha\beta$), ($\beta\beta\beta$), and ($\beta\alpha\beta$). *See also* **domain 2** (*in relation to protein sequences or sequence alignments*) a contiguous, conserved region, typically 10-20 amino acids in length, usually denoting a key structural or functional unit within a protein, or group of proteins, and often used to diagnose related sequences using pattern-recognition methods (such as fingerprinting). *Alternative name* **block**.

motile (of organisms or cells) capable of independent locomotion; (of cilia, flagella, etc.) capable of spontaneous movement. —**motility** *n*.

motilin a 22-residue peptide produced by **Mo cells** of the mucosa of the upper small intestine, and having putative hormonal activity. Its plasma level rises when food or alkali are placed in the duodenum; it stimulates contractions of the stomach and secretion of pepsin, but its effects show marked species variation.

motor (*in biology*) pertaining to movement of an organ or part; pertaining to nerves or neurons involved in muscular activity.

motor protein a protein, e.g. **dynein**, **kinesin**, **myosin**, that propels itself along a filament or polymeric molecule. Nucleoside triphosphate hydrolysis is usually necessarily involved. A similar process is thought to be involved in the action of elongation factor G (*see* **EF-G**). These processes are referred to as **chemical-mechanical coupling** (or mechanochemical coupling).

Motrin a proprietary name for **ibuprofen**.

mould or (*US*) **mold 1** any **microfungus** having a distinctive mycelium; *the common name for* any superficial growth of fungal mycelium. **2** a matrix for shaping a cast.

moult or (*US*) **molt 1** to cast off periodically an outer covering of cuticle, feathers, hair, horns, skin, etc. **2** the act, process, or condition of moulting; in invertebrates it is known as ecdysis.

moulting hormone or (*US*) **molting hormone** a *common name for* **ecdysterone**.

mouse-convulsion method a sensitive method for the detection and biological assay of insulin, used primarily to control the strength of pharmaceutical preparations of insulin. It is based on the finding that small doses of insulin injected into mice (0.1–1.0 μ g per animal) cause convulsions. When the method is used for assay, large equal numbers of animals are injected with either of two dilutions of the test solution or of a standard and the results are analysed statistically.

mouse mammary tumour virus *abbr.*: MMTV; a DNA virus that causes breast cancer in mice. It contains a powerful enhancer DNA sequence in the terminal repeats of the genome. This activates an oncogene called *wnt-1* (formerly called *int-1*), which is closely homologous to the *Drosophila* gene **wingless**. MMTV is often used as an **expression vector** especially in transgenic mice.

moving-boundary electrophoresis an analytical method of electrophoresis carried out using a **Tiselius apparatus**, formerly used for measuring electrophoretic mobility directly.

MOX *abbr.* for methanol oxidase (*see* **alcohol oxidase**).

m.p. *abbr.* for melting point.

MP *abbr.* for mitogenic protein (i.e. **interleukin 1**).

6-MP *abbr.* for 6-mercaptopurine.

MPF *abbr.* for M-phase-promoting factor.

M phase the period of mitosis and cytokinesis in the eukaryotic **cell-division cycle**. During this phase the nucleus and cytoplasm divide.

M-phase-promoting factor or **maturation-promoting factor** or **p34^{cdc}** *abbr.*: MPF; a protein complex, containing **cyclin** and a protein kinase, that triggers a cell to enter M phase of the **cell-division cycle**.

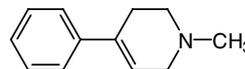

MPP *abbr.* for mitochondrial processing peptidase.

M6P receptor *abbr.* for **mannose 6-phosphate receptor**.

M protein 1 a structural protein that occurs in the M lines of myofibrils of striated muscle. **2** an *alternative name for* galactoside permease of *Escherichia coli*. **3** a cell-surface protein of Gram-positive

cocci, associated with virulence; it renders the organism resistant to phagocytosis. It is a cell-wall component, consisting of a coiled coil with a membrane anchor.

MPTP *abbr.* for 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine; a toxic by-product of the synthesis of heroin; it produces severe and permanent parkinsonism in primates, resulting from its oxidation by monoamine oxidase to the quaternary 1-methyl-4-phenyl-pyridinium (MPP⁺) ion. The latter is a potent inhibitor of complex I of the mitochondrial electron-transport chain and a selective neurotoxin for dopaminergic neurons, by which it is taken up in the substantia nigra via the normal neuronal dopamine re-uptake system.

MRC *abbr.* for Medical Research Council (of the UK).

MRCK *abbr.* for myotonic dystrophy kinase-related Cdc42-binding kinase; a protein-serine/threonine kinase that has sequence homology to **myotonic dystrophy protein kinase** and is activated by **Cdc42**.

MRE *abbr.* for metal response element; *see also* **response element**.

MREBP *abbr.* for metal response element binding protein.

MRF *abbr.* for melanotropin-releasing factor (*see* **MSHRH**).

MRF4 *abbr.* for muscle specific regulatory factor 4; *other name*: myogenic factor 6; a DNA-binding, probably **helix-turn-helix**, protein of the **MYC** family. It induces fibroblasts to differentiate into myoblasts.

MRH *abbr.* for melanotropin-releasing hormone (*see* **MSHRH**).

MRI *abbr.* for magnetic resonance imaging.

MRIF *abbr.* for melanotropin release-inhibiting factor (i.e. **melanostatin**).

MRIH *abbr.* for melanotropin-release inhibiting hormone (i.e. **melanostatin**).

mRNA *abbr.* for messenger RNA.

mRNA binding site (ribosome) a ribosomal binding region for mRNA. In bacteria this involves **ribosomal proteins** S1, S3, S4, S5, S12, S18, S21, and the 3' end of 16S rRNA.

mRNA splicing the process in which excision of **introns** from the primary transcript of **messenger RNA** (mRNA) is followed by ligation of the two **exon** termini exposed by removal of each intron, so that mRNA consisting only of the joined exons is produced. *See* **splicing** (def. 2).

mRNA surveillance the process occurring in the cytosol of eukaryotic cells whereby mRNA that contains a premature stop codon is detected and submitted to selective degradation by nonsense-mediated mRNA decay. It involves assembly of a surveillance complex on the mRNA about 24 nt upstream of exon-exon junctions. If translation terminates because of an upstream stop codon, translation release factors bind to the surveillance complex and trigger mRNA degradation.

mRNP *abbr.* for messenger ribonucleoprotein.

MRSA *abbr.* for **methicillin-resistant Staphylococcus aureus**, an organism resistant to antibiotics owing to the inability of penicillins to enter the cell (and not directly to β -lactamase). *Compare* **VRE**.

ms- *abbr.* for *meso-*.

MS *abbr.* for **1** mass spectrometer or mass spectrometry. **2** magic spot (compound). **3** multiple sclerosis.

MSA *abbr.* for multiplication-stimulating activity.

MSD *abbr.* for macromolecular structure database; *see* **structure database**.

msDNA *abbr.* for multicopy single-strand DNA.

MSEL-neurophysin *see* **neurophysin II**.

MSG *abbr.* for monosodium glutamate.

MSH *abbr.* for melanocyte-stimulating hormone.

MSHIF *abbr.* for melanocyte-stimulating-hormone release-inhibiting factor (i.e. **melanostatin**).

MSHII *abbr.* for melanocyte-stimulating-hormone release-inhibiting hormone (i.e. **melanostatin**).

MSHRF *abbr.* for melanocyte-stimulating-hormone releasing factor (i.e. **MSHRH**).

MSHRH *abbr.* for melanocyte-stimulating-hormone releasing hor-

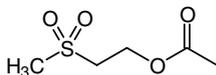

none; a pentapeptide, possibly identical to the N-terminal moiety of **oxytocin**, that is produced in the hypothalamus. In animals that show an unambiguous response of their melanophores to **melanotropin** this regulating factor is believed to promote melanotropin release. *Recommended name:* melanoliberin; *other names:* melanotropin-releasing factor (*abbr.:* MRF); melanotropin-releasing hormone (*abbr.:* MRH); melanocyte-stimulating-hormone releasing factor (*abbr.:* MSHRF).

MSHRIF *abbr. for* melanocyte-stimulating-hormone release-inhibiting factor (i.e. **melanostatin**).

MSRHIF *abbr. for* melanocyte-stimulating-hormone release-inhibiting hormone (i.e. **melanostatin**).

MS/MS *abbr. for* tandem mass spectrometry.

MSOC *abbr. for* the *N*-(2-methanesulfonyl)ethoxycarbonyl group; it is used as an amino-protecting group, its stability to acid, lability to alkali, and resistance to hydrogenation contributing to its usefulness. It is introduced using such reagents as **methylsulfonyl nitrophenyl carbonate** and **methylsulfonyl succinimidyl carbonate**.

Msp-300 a protein (8204 amino acids) of *Drosophila* that is probably involved in tethering nuclei to the cytoskeleton. Homologous with ANC-1 of *Caenorhabditis elegans* and mammalian Syne proteins, it contains two actin-binding domains, large central domains composed of spectrin repeats, and a C-terminal nuclear envelope transmembrane domain.

MSP *abbr. for* maximum-scoring segment pair.

MspI a type 2 **restriction endonuclease**; recognition sequence: C↑CGG. *HpaII* and *HapII* are **isoschizomers**. *MspI* is insensitive to methylation of the 5′C. *Compare HpaII*.

Mst1 *abbr. for* mammalian sterile twenty; a protein serine/threonine kinase that phosphorylates Ser14 of histone H2B. This phosphorylation correlates with the onset of apoptosis. Activity of the kinase is regulated by caspase-3.

MSX-1 or **Hox-7** a **homeobox** protein.

mtDNA *abbr. for* mitochondrial DNA.

MTOC *abbr. for* microtubule organizing centre.

mTor *abbr. for* mammalian target of rapamycin; *other name:* FKBP12-rapamycin-associated protein (*abbr.:* FRAP); a protein serine/threonine kinase that is inhibited by FKBP12-rapamycin. mTor phosphorylates the initiation factor eIF-4E and regulates S6 kinase and translation of mRNAs for ribosomal proteins and other components of the translation machinery. Its function is influenced by the intracellular concentration of ATP.

mtRNA *abbr. for* mitochondrial RNA.

MT-SP1 membrane type-serine protease I; *other name:* matriptase; a human type II transmembrane serine protease (855 amino acids) that is present in the gastrointestinal tract, liver, spleen, thymus, and placenta.

mu *symbol:* μ (lower case) or M (upper case); the twelfth letter of the Greek alphabet. For uses see **Appendix A**.

MU *abbr. for* 4-methylumbelliferyl.

mu chain or **μ chain** the heavy chain characterizing immunoglobulins belonging to the class IgM.

mucic acid *an old name for* galactaric acid, the *meso*-aldaric acid derived from both D- and L-galactose.

mucilage any of numerous proteoheteroglycans, frequently containing uronic acids, that occur widely in plants, especially in seed coats. Mucilages are hard when dry; in water, they swell, but do not dissolve, to form slimy masses with adhesive properties. *Compare gum.* —**mucilaginous** *adj.*

mucin any of a group of widely distributed glycoproteins of high M_r that are secreted by various animal mucous cells and glands; they occur, e.g., in saliva, gastric juice, and intestinal juice. Mucins form viscous solutions that act as lubricants and protectants of the linings of body cavities and of the skin.

mucinase *an alternative name for* **hyaluronidase**.

mucin domain *other name:* PTS region; a proline and threonine/serine-rich peptide sequence present in an apomucin. It contains 8–169 amino acids, is poorly conserved, and frequently tandemly repeated. It provides the sites for *O*-glycosylation. *See mucin.*

muco+ *comb. form of* mucus or mucin; mucoid.

mucoid 1 any **mucin**-like substance or mucoprotein. **2** of the nature of, or resembling, **mucus**. **3** describing a bacterial colony that has a gummy consistency, resulting from the abundant synthesis of capsular material.

mucolipid *an alternative name for* **ganglioside**.

mucolipidosis (*pl. mucolipidoses*) any of a group of inherited autosomal recessive diseases of humans characterized by deficiency of a variety of lysosomal hydrolases in connective tissue cells of patients, and in fibroblasts cultured from them. Mucolipidosis I, commonly known as **sialidosis**, is due to a deficiency of neuraminidase that leads to accumulation of sialyl oligosaccharides, and excretion of these in the urine. In mucolipidosis II, the cytoplasm of cultured cells from affected patients contains numerous highly refractile inclusions, visible by phase-contrast microscopy. These are very large lysosomes containing heterogeneous material, mucopolysaccharides, glycolipids, and whorls of membranes, giving this the name **I-cell** (inclusion cell) **disease**. Mucolipidosis III is due to a deficiency of *N*-acetylglucosamine 1-phosphotransferase.

mucolytic having the ability to disrupt mucus.

muconate *a trivial name for* any one of the three stereoisomers (*cis,cis*, *cis,trans*, or *trans,trans*) of 2,4-hexadienedioate; 1,3-butadiene-1,4-dicarboxylate; $^-\text{OOC}-\text{CH}=\text{CH}-\text{CH}=\text{CH}-\text{COO}^-$, the dianion derived from muconic acid. The *cis,cis* isomer is an intermediate in the degradation of catechol by microorganisms.

muconolactone Δ-isomerase EC 5.3.3.4; an enzyme that catalyses the reaction:

in the pathway for the degradation of catechol to acetyl-CoA.

mucopeptide (*sometimes*) *an alternative name for* **peptidoglycan**.

mucopolysaccharide any of a group of acid heteroglycans built up of characteristic repeating disaccharide units each consisting of an *N*-acylated hexosamine residue and a uronic-acid residue; many mucopolysaccharides also contain sulfate. The group includes hyaluronic acid (*see* **hyaluronate**), **chondroitin sulfate**, **dermatan sulfate**, **keratan sulfate**, **heparin**, and some **blood-group substances**.

mucopolysaccharide storage disease any of a group of clinically progressive, hereditary diseases of humans characterized by the accumulation of mucopolysaccharides in various tissues. They include the **mucopolysaccharidoses** and the **mucolipidoses**.

mucopolysaccharidosis (*pl. mucopolysaccharidoses*) any of a group of clinically progressive, hereditary diseases of humans each of which is characterized by the deficiency of a single lysosomal hydrolase concerned in the degradation of mucopolysaccharides. They have been classified into a number of types. *See* individual entries below.

mucopolysaccharidosis IH or **Hurler syndrome** a **mucopolysaccharidosis** caused by a deficiency in lysosomal L-iduronidase (EC 3.2.1.76) that affects the degradation of both dermatan sulfate and heparan sulfate. It is inherited as an autosomal recessive disorder. Subjects excrete excessive amounts of both dermatan sulfate and heparan sulfate in the urine in the ratio of approximately 7:3. The biochemical lesion is the same as in mucopolysaccharidoses IH/S and IS, from which differentiation can only be made by clinical criteria.

mucopolysaccharidosis IH/S or **Hurler–Scheie compound syndrome** a **mucopolysaccharidosis** caused by the same deficiency in lysosomal L-iduronidase (EC 3.2.1.76) as is found in mucopolysaccharidoses IH and IS. It is inherited as an autosomal recessive disorder and it is believed to be a phenotype intermediate between these two syndromes, one mutant allele being inherited from the father and a different mutant allele from the mother. The condition can only be differentiated from mucopolysaccharidoses IH and IS by clinical criteria.

mucopolysaccharidosis IS or **Scheie syndrome** (*formerly*) **mucopolysaccharidosis V** a **mucopolysaccharidosis** caused by the same

deficiency in lysosomal L-iduronidase (EC 3.2.1.76) as is found in mucopolysaccharidoses IH and IH/S. It is inherited as an autosomal recessive disorder and it has a milder clinical course than mucopolysaccharidoses IH and IH/S, from which it can be differentiated only by clinical criteria.

mucopolysaccharidosis II or **Hunter syndrome** a **mucopolysaccharidosis** caused by a deficiency in iduronate sulfatase that affects the degradation of both dermatan sulfate and heparan sulfate. It is inherited as an X-linked recessive disorder, and several different mutations of the same X-chromosome locus probably account for the different severities of the disease seen in various families. Subjects excrete excessive and roughly equal amounts of both dermatan sulfate and heparan sulfate in the urine.

mucopolysaccharidosis IIIA or **Sanfilippo syndrome A** a **mucopolysaccharidosis** caused by a deficiency in heparan *N*-sulfatase that affects the degradation of heparan sulfate. It is inherited as an autosomal recessive disorder and is indistinguishable clinically from mucopolysaccharidosis IIIB. Subjects excrete excessive amounts of heparan sulfate in the urine.

mucopolysaccharidosis IIIB or **Sanfilippo syndrome B** a **mucopolysaccharidosis** caused by deficiency in α -*N*-acetyl-D-glucosaminidase (EC 3.2.1.50) that affects the degradation of heparan sulfate. It is inherited as an autosomal recessive disorder and is indistinguishable clinically from mucopolysaccharidosis IIIA. Subjects excrete excessive amounts of heparan sulfate in the urine.

mucopolysaccharidosis IIIC (*abbr.*: MPS IIIC) or **Sanfilippo syndrome C** a mucopolysaccharidosis (MPS) that is clinically similar to MPS IIIA, IIIB, and IIID but caused by deficiency of lysosomal acetyl-CoA: α -glucosaminidase acetyl transferase, which affects the degradation of heparan sulfate. Subjects excrete excessive amounts of heparan sulfate in urine.

mucopolysaccharidosis IIID (*abbr.*: MPS IIID) or **Sanfilippo syndrome D** a mucopolysaccharidosis (MPS) that is clinically similar to MPS IIIA, IIIB, and IIIC, but caused by deficiency of *N*-acetyl glucosamine 6-sulfatase, which affects the degradation of heparan sulfate. Subjects excrete excessive amounts of heparan sulfate in urine.

mucopolysaccharidosis IVA (or **IVA**) or **Morquio A disease** a mucopolysaccharidosis caused by a deficiency of lysosomal *N*-acetyl-galactosamine-6-sulfatase, leading to an accumulation of keratan sulfate and chondroitin 6-sulfate. It is inherited as an autosomal recessive disorder.

mucopolysaccharidosis IVB (or **IVb**) or **Morquio B disease** a mucopolysaccharidosis caused by a deficiency of β -galactosidase leading to accumulation of keratan sulfate. It is inherited as an autosomal recessive disorder.

mucopolysaccharidosis V a former name for **mucopolysaccharidosis I S**.

mucopolysaccharidosis VI or **Maroteaux-Lamy syndrome** a **mucopolysaccharidosis** caused by a deficiency of lysosomal *N*-acetyl-galactosamine 4-sulfatase that affects the degradation of dermatan sulfate. Three clinically distinguishable forms are known: severe, intermediate, and mild; all are inherited as autosomal recessive disorders, with probably two or more mutant alleles at the mucopolysaccharidosis VI locus, one of which produces the severe form when homozygous and the other the mild form. Subjects excrete excessive amounts of dermatan sulfate in the urine.

mucopolysaccharidosis VII a **mucopolysaccharidosis** caused by a deficiency of lysosomal β -D-glucuronidase (EC 3.2.1.31) that affects the degradation of both dermatan sulfate and heparan sulfate. It is inherited as an autosomal recessive disorder.

mucopolysaccharidosis IX (*abbr.*: MPS IX) or **hyaluronidase deficiency** a rare mucopolysaccharidosis caused by deficiency of lysosomal endohexosaminidase (hyaluronoglucosaminidase; EC 3.2.1.35), which is responsible for degradation of hyaluronates primarily to a tetrasaccharide. Subjects excrete excessive amounts of hyaluronate in urine. The gene for the enzyme is at 3p21.2-p21.3.

mucoprotein any glycoprotein containing relatively large amounts of acidic polysaccharide.

mucosa (*pl.* **mucosae**) or **mucous membrane** any of the moist membranes that line the alimentary canal, the glandular ducts, and the respiratory, urinary, and genital passages; it may be smooth, corrugated, or covered with villi. Mucous membranes consist of a surface

layer of epithelium containing mucus-secreting glands, and an underlying layer of connective and muscular tissue. *Compare* **serosa**. —**mucosal** *adj.*

mucotetraose *symbol*: McOse₄ or Mc₄ (if space is limited); the tetrasaccharide Gal(β 1-3)Gal(β 1-4)Gal(β 1-4)Glc.

mucotriaose *symbol*: McOse₃ or Mc₃ (if space is limited); the trisaccharide Gal(β 1-4)Gal(β 1-4)Glc.

mucous relating to, resembling, or secreting **mucus**.

mucous cell any cell that secretes **mucus**.

mucous gland any exocrine gland consisting predominantly of **mucus**-secreting cells.

mucous membrane an alternative name for **mucosa**. *Compare* **serous membrane**. —**mucomembranous** *adj.*

mucus the slimy, sticky, viscous secretion, consisting predominantly of **mucins**, that is secreted by mucous cells of the mucosae and of the external body surface of some animals.

MUG *abbr. for* **1** either 4-methylumbelliferyl-glucuronide or 4-methylumbelliferyl- β -D-galactopyranoside. Both compounds are fluorogenic enzyme substrates that yield 4-methylumbelliferone. *See also* 4-methylumbelliferyl. **2** murinoglobulin.

MUGal *abbr. for* 4-methylumbelliferyl- β -D-galactopyranoside (alternative to MUG).

muineic acid a phytosiderophore secreted by the roots of barley plants. It is derived from the α -aminobutyrate moieties of three molecules of *S*-adenosylmethionine by the action of nicotinamine synthase.

mull a suspension of very finely ground solid in an inert liquid, especially paraffin or **Nujol**, that is used in infrared spectroscopy of the solid.

Müllerian inhibiting factor an alternative name for **anti-Müllerian hormone**.

multi+ *comb. form* denoting more than one, several. *See also* **poly+**.

multicatalytic endopeptidase complex *see* **proteasome**.

multicellular having, or consisting of, several or many cells.

multichain (*of a protein*) consisting of two or more polypeptide chains connected by non-peptide links.

multichannel analyser any instrument or device for sorting a heterogeneous input into a number of ranges, e.g. of frequency or energy, and determining the relative proportions in each range.

multichannel pipette a plunger-operated pipette used for dispensing fluids in the microlitre range that is designed to deliver 4–8 samples of the same volume in parallel. The tips of the pipette have the same spatial separation as the wells on a **microtitre plate**.

multicopy single-strand DNA *abbr.*: msDNA; DNA generated by bacterial reverse transcriptase and found in certain Gram-negative bacteria. The molecules are unique in being the only known naturally occurring examples of nucleic acids containing an RNA–DNA covalent link.

multidentate (*of a ligand*) having two or more groups through which it can be attached to a central atom. Such a ligand is able to form a bridge or a chelate.

multidimensional chromatography a technique in which a single component separated from a mixture by chromatography on one type of column may be automatically transferred, as a sample, for chromatography on another type of column in order to effect further resolution.

multidrug resistance *see* **MDR**.

multidrug transporter a superfamily of integral membrane proteins found in nearly all cells. They bind to structurally and chemically diverse compounds and remove them from cells using energy derived from ATP or protonmotive force. First discovered in mammalian cells (*see* **MDR**) they also occur in bacteria and yeast. There are four classes: (1) ATP-binding cassette (ABC) transporters; (2) major facilitator (MRF) transporters; (3) small multidrug-resistance (SMR) transporters; and (4) resistance-nodulation (RND) transporters. The first class is ATP-dependent, the other three classes are proton-dependent.

multienzyme the recommended class name for any protein that possesses two or more autonomous catalytic functions due to separate catalytic domains (*see* **domain**, def. 3), whether contributed by distinct subunits (*see* **multienzyme complex**), by distinct parts of an individual polypeptide chain (*see* **multienzyme polypeptide**), or by both.

Excluded is any enzyme that can catalyse different reactions at the same catalytic centre. *Compare enzyme complex, multienzyme system.*

multienzyme cluster *see enzyme cluster.*

multienzyme complex *the recommended subclass name for any multienzyme in which catalytic domains occur on more than one type of polypeptide chain. A multienzyme complex may itself contain a multienzyme polypeptide.*

multienzyme polypeptide *the recommended subclass name for any multienzyme in which at least two demonstrably distinct catalytic domains of different types occur on a single polypeptide chain and are encoded by a single gene. A multienzyme polypeptide may itself be a component of a multienzyme complex. Compare multifunctional protein.*

multienzyme system *an operational term for any system of two or more enzymes functioning sequentially to catalyse the reactions of a metabolic pathway, so that the product of the first enzyme becomes the substrate of the second and so on. Three levels of organization of multienzyme systems may be discerned. First, the individual enzymes are independently in solution in a compartment within a cell and are not directly associated with each other when acting. Second, the individual enzymes are physically associated and function together as an enzyme complex, or they occur as a multienzyme. Third and most highly organized, the individual enzymes are associated with large, supramolecular structures such as membranes or ribosomes. See also enzyme cluster, metabolon.*

multifactorial 1 involving or dependent on more than one factor or causes. **2** (*in genetics*) inheritance depending on more than one gene.

multifunctional protein any protein that combines two or more autonomous functions on one polypeptide chain, the functions being both independently measurable and assignable to separate domains of the protein. Such functions may or may not be catalytic (*compare multifunctional protein ade2*). Excluded are allosteric enzymes, proenzymes, and enzymes that can catalyse different reactions at a single reaction centre.

multifunctional protein ade2 a protein that contains phosphoribosylaminoimidazolesuccinocarboxamide synthase and phosphoribosylaminoimidazole carboxylase and is involved in the sixth and seventh steps in *de novo* purine biosynthesis. The human enzyme consists of 425 amino acids; the synthase domain resides in residues 1–260, the carboxylase domain in residues 261–425.

multigenic describing a phenotype that results either from the inheritance of more than one mutant allele, or the interaction of a number of genes and environmental factors.

multiiodinated describing any compound that has been reacted so as to contain two or more atoms of iodine per molecule.

multilamellar occurring as, or made up of, several discrete layers.

multilayered film analyser a device for the rapid determination of any of a range of components present in small volumes of biological fluids. It depends on a single-use reagent slide on which the various chemicals required are present in dry form as a series of thin films. These consist successively of an indicator layer, a semipermeable layer, a reagent layer, and a spreading layer, all mounted between two transparent supports. Typically, a 10 μ L sample is applied to the spreading layer, a chemical or enzymatic reaction occurs in the reagent layer, and the semipermeable layer withholds macromolecular substances from the indicator layer, where usually a dye combines with a product of the reaction to form a coloured compound. The intensity of the colour, which is proportional to the quantity of the analyte in the specimen, is measured by reflectance spectrophotometry. The concept has been extended to the use of potentiometry for the measurement of sodium and potassium.

multilocus enzyme any of a set of enzymes, with similar catalytic properties and existing in the same organism, whose amino-acid sequences are encoded in nonallelic structural genes at two or more separate loci. There may be marked variations in the expression of the individual loci in different tissues. A class of **isoenzyme**.

multimer any specific aggregate of (identical or nonidentical) molecular entities held together by noncovalent bonds. —**multimeric adj.**; **multimerize** or **multimerise vb.**; **multimerization** or **multimerisation n.**

multinucleate or **multinuclear** (of a cell) containing several or many nuclei.

multipass (*in protein biochemistry*) describing an integral membrane protein that contains more than one transmembrane segment. *Compare single-pass.*

multiphase having several phases; polyphase.

multiple alignment *see alignment.*

multiple alignment program (*in sequence analysis*) software for aligning more than two sequences of biopolymers. Evolutionarily rigorous multiple alignment is computationally intractable, and is therefore most often effected by means of heuristic techniques that progressively align pairs of aligned sequences: e.g. Clustal, T-Coffee. *See alignment.*

multiple cloning site a short DNA sequence in a cloning vector that incorporates recognition sites for a number of restriction endonucleases, which cut the vector only at this point. Their presence affords a choice of individual sites for cloning DNA or, by using two different sites, the possibility of cloning a DNA fragment in a desired orientation with respect to the vector. Also known as a **polylinker**.

multiple codon recognition the recognition by a single tRNA molecule of more than one type of codon in mRNA.

multiple development technique a chromatographic technique in which the chromatogram is developed more than once with either the same solvent system or a different one with the aim of improving the separation.

multiple drug resistance *see MDR.*

multiple forms (of an enzyme) *the recommended collective term to describe all proteins that possess the same (specified) enzymic activity and occur naturally in a single species. It includes, but is not limited to, isoenzymes; the term isoenzyme should be applied only to multiple forms that arise from genetically determined differences in primary structure, and some limit this to those arising from a single gene locus.*

multiple myeloma or **multiple myelomatosis** *see myeloma.*

multiple osteochondromata *an alternative name for hereditary multiple exostoses.*

multiple sclerosis *abbr.*: MS; a chronic and usually progressive disease of the nervous system, also known as disseminated sclerosis, in which the myelin sheaths surrounding the axons in the central nervous system are lost. The cause is unknown. It is generally considered to be a T-lymphocyte-mediated autoimmune disorder targeted at myelin-specific components. A major antigen during the inflammatory phase is α B-crystallin. It is accompanied by formation of plaques, microscopic to macroscopic in size and containing activated lymphocytes and monocytes. The disease is characterized by a course of relapses and remissions over a number of years.

multiplet any group of two or more associated spectral lines. In electronic spectra the lines of a multiplet are very closely spaced and appear at low resolution as a single line, whereas in nuclear magnetic resonance spectra the separation may be considerable.

multiplicand (*in mathematics*) a number to be multiplied by another number – the multiplier – in an arithmetic multiplication.

multiplication-stimulating activity *abbr.*: MSA; an activity found in mammalian serum and produced by some animal cells that is required for the multiplication of animal cells in culture.

multiplicity (*in physics*) the number of components in a multiplet.

multiplicity of infection the ratio of the number of virus particles to the number of susceptible cells in a given system.

multiplicity reactivation the reconstruction of viable genomes in a cell that is multiply infected with otherwise nonviable viruses.

multiplier 1 (*in mathematics*) any number by which another number – the multiplicand – is multiplied. **2** any instrument or device for multiplying an effect, e.g. photomultiplier.

multiplying prefix a prefix to denote the presence of several identical substituents in a molecule, at different positions. The prefix 'bis' indicates two substituents, for example fructose-1,6-bisphosphate; by contrast the prefix 'di' indicates that both substituents are linked at the same position, e.g. adenosine diphosphate. 'tris' corresponds to three substituents, and subsequently the names are formed by adding the ending 'kis' to the basic multiplying prefix ending in 'a', e.g. 'tetrakis', 'pentakis', 'hexakis'.

multiply labelled describing an isotopically substituted compound that has more than one modified atom of the same element at the same position or at different positions.

multipotent (of a cell or tissue) capable of giving rise to several kinds of cells, tissues, or structures. *Compare pluripotent* (def. 2).

multisubstrate enzyme any enzyme that requires two or more substrates in order to catalyse a particular reaction.

multiubiquitin *see polyubiquitin*.

multivalent *an alternative term for polyvalent*.

multivalent phosphorylation the phosphorylation of any hormonally regulated enzyme at a plurality of sites by two or more distinct kinase enzymes, with a resultant increase in the regulatory potential of the enzyme.

multivesicular body an intracellular structure that is lined by a single membrane and contains a number of inner vesicles that are approximately 50 nm in diameter. It is a form of secondary **lysosome**.

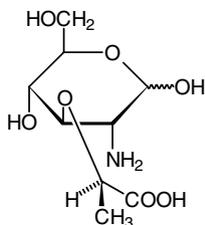

multi-wavelength anomalous dispersion *abbr.*: MAD; a method for solving macromolecular structures containing different elements by X-ray crystallography, in which the phases are resolved by diffraction at X-ray wavelengths near to an absorption edge of the element.

MunI a type 2 **restriction endonuclease**; recognition sequence: C \uparrow AATTG. *MfeI* is an **isoschizomer**.

mupirocin a substance produced by *Pseudomonas fluorescens* and active against Gram-negative bacteria. It is used to treat impetigo and skin infections. It inhibits protein synthesis by reversibly and specifically binding to isoleucine transfer-RNA ligase (*see transfer RNA*).

Mur *symbol for a residue (or sometimes a molecule) of muramic acid*.

muramic acid *symbol*: Mur; 3-*O*- α -carboxyethyl-D-glucosamine; the 3-*O*-D-lactyl ether derivative of D-glucosamine. It occurs naturally in peptidoglycan of bacterial cell walls.

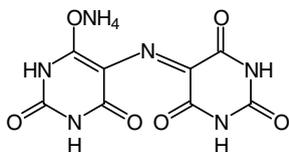

muramidase *an alternative name for lysozyme*.

muramyl the acyl group derived from **muramic acid**.

muramyl-dipeptide *abbr.*: MDP; *N*-acetyl-muramyl-D-alanyl-D-isoglutamine; a synthetic, water-soluble, **peptidoglycan** derivative that is capable of replacing whole mycobacteria in complete **Freund's adjuvant**. It is highly active in stimulating antibody production against an antigen injected simultaneously.

murein *an alternative name for peptidoglycan*.

murexide ammonium purpurate; 5,5'-nitrilodibarbituric acid monoammonium salt; a compound that forms a purple-red solution in water. It is useful as an indicator in complexometric titration of calcium, nickel, cobalt, copper, etc. with EDTA.

murexide test a colour test for uric acid and some other purines. The (solid) sample is first treated with conc. nitric acid, which is slowly evaporated away; subsequent addition of ammonia solution gives a purple colour if uric acid was present, due to formation of

murexide, or a yellow colour that turns to red on heating if xanthine was present.

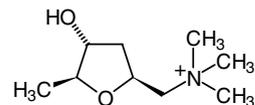

murine of, belonging to, characteristic of, affecting, transmitted by, or being a member of the Muridae, a family of small rodents that includes mice and rats; of or relating to the mouse genus, *Mus*.

murine toxin or **Yersinia murine toxin** the product of the *Ymt* gene on a plasmid of *Yersinia pestis* (the causative agent of bubonic plague). It belongs to the phospholipase D family of enzymes and causes hypotension and vascular failure as a result of release from lysing bacteria during the terminal stages of septicemic plague. It is required for survival of the *Yersinia* bacteria in the midgut of the rat flea *Xenopsylla cheopis*.

murinoglobulin *abbr.*: MUG; a monomeric protease inhibitor found in blood plasma of vertebrates and invertebrates, and in egg white of birds and reptiles. It has a characteristic **bait region**. *Compare* α_2 **macroglobulin**.

muropeptide *an alternative name for peptidoglycan*.

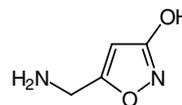

muscarine a toxic alkaloid (quaternary ammonium base) found in the red variety of *Amanita muscaria* (fly agaric) and some other gill fungi. It is an agonist for one type of **cholinoceptor**.

(+)-enantiomer

muscarinic receptor *see cholinoceptor*.

muscimol 5-aminomethyl-3-hydroxyisoxazole; an isoxazole isolated from the fungus *Amanita muscaria*. A hallucinogen and potent CNS depressant, it is a selective agonist of GABA_A receptors.

muscle 1 a tissue made up of various elongated cells that are specialized to contract and thus to produce movement and mechanical work. **2** an organ consisting principally of muscle tissue. *See cardiac muscle, smooth muscle, striated muscle*. —**muscular** *adj.*

muscle contraction *see sliding filament model*.

muscle hemoglobin *a former name for myoglobin*.

muscle sugar *a former name for inositol* (def. 1).

muscular dystrophy any genetically determined disease of humans in which there is progressive muscular weakness and evidence of muscle degeneration. All are characterized by creatinuria, and serum creatine phosphokinase activity is elevated in several of them. *See also dystrophin*.

musculin *see capsulin*.

mushroom sugar *a former name for trehalose*.

Musk *abbr. for muscle-specific kinase*; a skeletal muscle-specific receptor-tyrosine kinase found at neuromuscular junctions. It may be involved in clustering of acetylcholine receptors and dystroglycans.

mustard gas sulfur mustard; bis(2-chloroethyl)sulfide; a colourless oily liquid with a very low vapour pressure. It is a powerful vesicant and also a mutagen and carcinogen. *See also nitrogen mustard*.

mustard oil any alkyl isothiocyanate, of general formula R-N=C=S. Such compounds have a pungent mustard-like smell and are present in the tissues of a number of plants, either free or as thioglycosides.

mut any of a family of genes whose products are involved in **mismatch repair**. All the following examples are from *Escherichia coli*. The product of *mutH* is a repair endonuclease that is specific for unmethylated GATC sequences. The protein encoded by *mutL* is also

involved in repair of mismatches in DNA and is required for activity of the *dam* product. The protein encoded by *mutS*, again involved in mismatch repair (possibly the recognition step), has weak ATPase activity.

mutable able or tending to undergo change or **mutation**. —**mutability** *n*.

mutable gene any gene that spontaneously mutates at a high rate.

mutable site any site on a chromosome at which mutations can occur.

mutagen any physical or chemical agent that is capable of increasing the frequency of **mutation** above the spontaneous, background level. —**mutagenic** *adj.*; **mutagenicity** *n*.

mutagenesis the production of mutations.

mutagenize or **mutagenise** to treat (cells or organisms) with a mutagen. —**mutagenized** or **mutagenised** *adj*.

mutant 1 a any organism that has arisen by or has undergone **mutation**, or one that carries a mutant gene that is expressed in the phenotype of that organism. **b** a mutant gene. **2** produced by or following a mutation; having the attributes of a **mutant** (def. 1).

mutarotation the spontaneous change in the optical rotation of a freshly prepared solution of a pure stereoisomer, especially a carbohydrate, that is caused by epimerization, or some other structural change.

mutase any enzyme that catalyses (or apparently catalyses) an intramolecular transfer of a chemical group. Such enzymes belong to one of the following EC sub-classes: EC 5.4.1, transferring acyl groups; EC 5.4.2, transferring phosphoryl groups; EC 5.4.3, transferring amino groups; EC 5.4.99, transferring other groups.

mutate to undergo or cause to undergo mutation.

mutation 1 the process by which genetic material undergoes a detectable and heritable structural change, or the result of such a change. Three categories are recognized: **genome mutations**, in which addition or subtraction of one or more whole chromosomes occurs; **chromosome mutations**, in which the structure of one or more chromosomes is affected; and **gene mutations**, in which the structure of a gene is altered at the molecular level. **2** any modified gene arising from a **mutation** (def. 1). **3** a **mutant** (def. 1). *See also* **deletion**, **inversion** (def. 4), **point mutation**, **translocation** (def. 2).

mutational heteroduplex *see* **heteroduplex**.

mutation bias bias in the mutation frequencies of different codons, affecting the synonymous to nonsynonymous rate ratio. Mutation bias results in an accelerated rate of amino acid replacement in functionally less constrained regions.

mutation frequency the frequency at which a mutation occurs in a population. It may or may not reflect the **mutation rate**, with which it is sometimes used interchangeably.

mutation frequency decline the significant and irreversible reduction in the frequency of some UV-induced mutations in bacteria during the temporary post-irradiation inhibition of protein synthesis.

mutation matrix *an alternative name for substitution matrix*.

mutation pressure the continued production of an allele by mutation that tends to increase the allele's frequency in the gene pool.

mutation rate 1 the probability that a particular mutation will occur per virus, cell, or organism during a reproductive cycle. **2** the frequency at which any mutation or mutational class occurs in a given population; **mutation frequency**.

mutator gene any gene that produces an increase in spontaneous mutation rates. Their action may be limited to certain alleles or to certain mutational pathways.

mutain a mutant protein produced by site-specific mutagenesis or other recombinant DNA technique.

MutH a protein of *E. coli* that is involved, with **MutS** and **MutL**, in DNA mismatch repair. No homologue appears to have been found in eukaryotic cells. It functions as a site-specific endonuclease.

MutL a protein of *E. coli* that is involved, with **MutS** and **MutH**, in DNA mismatch repair. MutL homologues (*abbr.*: MLH) are present in all eukaryotic cells. Mutations in the human homologue (hMLH) are common in hereditary nonpolyposis colon cancer.

muton the smallest unit of genetic material whose alteration may give rise to a mutation; commonly supposed to be a single nucleotide (pair).

MutS a homodimeric mismatch-binding protein of *E. coli* that is involved, with **MutH** and **MutL**, in DNA mismatch repair. MutS homologues (*abbr.*: MSH) exist in all eukaryotic cells. In yeast they are called MSH1 and MSH2. Mutations in the human homologue (hMSH2) are common in hereditary nonpolyposis colon cancer.

MVA *abbr.* for mevalonic acid (use discouraged).

MvaI a type 2 **restriction endonuclease**; recognition sequence: CC↑[AT]GG. *EcoRII* is an **isoschizomer**.

M13 vector a DNA cloning vector based on the genome of the filamentous bacteriophage M13. In some **phagemids** only the M13 origin of replication is used.

MVG *abbr.* for methoxyvinylglycine.

MVP *abbr.* for major vault protein. *See* **vault**.

M.W. *abbr.* for molecular weight (alternative to mol. wt.).

MWC model *abbr.* for Monod–Wyman–Changeux model.

my+ a variant form of **myo+** (before a vowel).

MYB a gene family that encodes DNA-binding proteins; *v-myb* is the oncogene of the acutely transforming avian myeloblastosis virus. It is highly conserved between mammalian species. The product, Myb, contains DNA-binding, transcriptional activation, and negative regulatory domains; it recognizes YAAC(G/T)G. It is notably associated with cells of the hemopoietic lineage and is essential for normal hemopoiesis. It is expressed in some human malignant tumours. [From 'myeloblastosis'.]

MYC a family of genes encoding short-lived nuclear regulatory proteins that act as transcription factors, e.g. pp64/pp67 (based on expressed mass). The oncogene, *v-myc*, was originally identified in avian myelocytomatosis virus, MC29, but is also carried by the avian retroviruses CM11 and OK-10. The protooncogene, *c-myc*, is a member of a family of at least seven related genes: *myc*, *B-myc*, *N-myc*, *L-myc*, *P-myc*, *R-myc*, and *S-myc*; *B-Myc* lacks the basic helix-loop-helix leucine zipper (bHLHLZ) domains of other Myc proteins. The product of *c-myc* binds nonselectively to DNA and (with higher affinity) to CAC[GA]TG. In normal cells *myc* expression is strictly dependent on mitogenic stimuli and is required for cell proliferation as well as to prevent cell differentiation. Induction of *c-myc* in the absence of growth factors is sufficient to drive rodent fibroblasts into the cell cycle but concomitantly induces apoptosis unless specific survival cytokines are present. Structurally, the product Myc contains an N-terminal transactivation domain that activates transcription of the gene with which it interacts, and a C-terminal bHLHLZ motif, which is known to mediate Myc dimerization and sequence-specific DNA binding. Although Myc–Myc dimers can form in solution, Myc homodimers are not detected *in vivo*, dimers forming with other partners, e.g. Max, which has a bHLHLZ motif but no transactivation domain (*see* **MAX**). *In vitro*, Myc–Max (and Myc–Myc) dimers have been found to bind DNA with a core sequence of CACGTG. Unlike Myc, Max is a stable protein expressed constitutively in growing, resting, and differentiating cells, and is capable of binding further proteins, e.g. Mad and Mxi, which compete with Myc for binding. The *myc* gene may be activated to become a transforming gene by proviral insertion, chromosomal translocation, or gene amplification, but generally protein structure is not affected; **Philadelphia chromosome** is one example. The *myc* gene has been implicated in various neoplasms in birds, mice, and humans, oncogenic activation occurring mainly through constitutive and elevated expression of the Myc protein. [From 'myelocytomatosis'.]

myc+ a variant form of **myco+** (before a vowel).

mycarose 2,6-dideoxy-3-C-methyl-L-ribo-hexose; a component of several **macrolide** antibiotics.

mycelia the plural of **mycelium**.

mycelium (*pl.* **mycelia**) the network or mass of discrete hyphae that forms the body (thallus) of a fungus. —**mycelial** *adj*.

myceto+ or (before a vowel) **mycet+** *comb. form* denoting fungus.

myco+ or (before a vowel) **myc+** *comb. form* denoting fungus.

mycobacterium (*pl.* **mycobacteria**) any bacterium belonging to the genus **Mycobacterium**.

Mycobacterium a genus of Gram-positive, aerobic, nonmotile, non-spore-forming, acid-fast bacteria of the family **Mycobacteriaceae**. The cells are rodlike and can form filaments or branched structures; their cell walls characteristically contain **mycolic acid**.

Some species are pathogenic to humans and/or other animals, e.g. *M. tuberculosis* (the tubercle bacillus) and *M. leprae* (the leprosy bacillus).

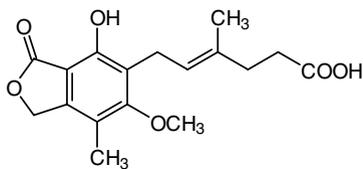

mycobactin any of a family of **siderochromes** of the hydroxamic acid-derivative category, produced by various species of *Mycobacterium*. At least nine have been characterized.

mycolic acid any of a family of α -substituted β -hydroxylated very-long-chain fatty acids of general formula $R_2-CH(OH)-CHR_1-COOH$, where R_1 is a $C_{20}-C_{24}$ linear alkyl group and R_2 is a complex $C_{30}-C_{60}$ group of very variable structure. They occur naturally as esters of arabinose in the cell walls of *Mycobacterium* spp., *Nocardia* spp., and *Corynebacterium* spp. and as esters of trehalose in **cord factor**. See also **cyclic fatty acids**.

mycology the scientific study of fungi. —**mycological** or **mycologic** *adj.*; **mycologist** *n.*

mycolyl the generic name for acyl groups derived from **mycolic acids**.

mycophenolic acid 6-(1,3-dihydro-4-hydroxy-6-methoxy-7-methyl-3-oxo-5-isobenzofuranyl)-4-methyl-4-hexenoic acid; an antibiotic and antitumour material from *Penicillium brevicompactum*. It was first isolated in 1896, and said by the Australian physiologist Howard Florey (1898–1968) to be ‘the first antibiotic produced by a mould to be crystallized’. As the morpholinoethyl ester (mycophenolate mofetil) it is an approved immunosuppressant in renal transplantation. Transformed mammalian cells expressing *E. coli* guanine phosphoribosyltransferase (GPT) are resistant to mycophenolic acid if grown in a medium supplemented with xanthine.

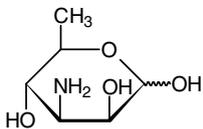

mycoplasma or (formerly) **pleuropneumonia-like organism** (*abbr.*: PLO) any member of the Mycoplasmatales, an order of minute, Gram-negative, prokaryotic microorganisms that are the smallest known free-living organisms. They have no cell walls (except for some saprophytic species), are variable in form, and can pass through bacteria-retaining filters. Some are saprophytic while others are pathogenic to humans, other animals, and plants. Mycoplasmas frequently infect tissue cultures. They were once thought to be the same as **L forms**. A newer classification replaces mycoplasma as a trivial name for members of the entire class by the term **mollicute**, and the class is called Mollicutes. The trivial name ‘mycoplasma’ is then restricted to members of the genus *Mycoplasma*.

Mycoplasma the main genus of **mycoplasmas**.

mycoprotein a commercially produced protein-containing food-stuff derived from moulds grown on carbohydrate substrates.

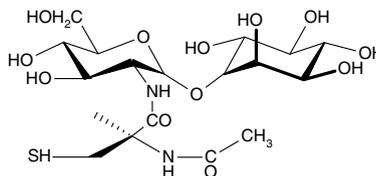

mycosamine 3-amino-3-deoxy-D-rhamnose; 3,6-dideoxy-3-amino-D-mannose; an amino sugar that contributes the nitrogen-containing moiety of the polyene antibiotics **amphotericin B** and **nystatin**.

mycose a common name for **trehalose**.

mycostatic describing any agent that inhibits the growth of fungi; fungistatic.

mycothiol 1-O-(2-[N-acetyl-L-cysteinyl]amido-2-deoxy- α -D-glucopyranosyl)-D-myoinositol, the major low-molecular-mass thiol in mycobacteria; it is associated with the protection of *Mycobacterium tuberculosis* from oxidants and antibiotics.

mycotoxin any poisonous substance produced by a fungus that is not a mushroom. Examples include aflatoxin, ochratoxin, and patulin.

myelo+ a variant form of **myelo+** (before a vowel).

myelin the material that constitutes the **myelin sheaths** surrounding vertebrate nerve axons. It is rich in lipid, particularly in glycolipid. See also **myelin protein**.

myelination the process by which a nerve axon acquires a **myelin sheath**.

myelin protein any of the proteins that form part of the **myelin sheath**. In the following descriptions, all examples are of human precursor sequences. **Myelin-associated glycoprotein**, a cell adhesion molecule for postnatal neural development, is a member of the immunoglobulin superfamily; it is an integral membrane protein. **Myelin basic protein**, a protein of the cytoplasmic face of the myelin membrane, is a major protein component of normal myelin of the central nervous system (CNS). Very basic in nature (pI > 10.5), it is a single-chain protein with little structure. Administration of myelin basic protein in complete **Freund's adjuvant** in various experimental animals elicits experimental allergic encephalitis, owing to induction of delayed hypersensitivity to the protein, which is thought to have an important role in causing demyelinating diseases in humans. Three forms are produced by alternative splicing. **P2** is probably a lipid transport protein; it is found in Schwann cells, associated with myelin basic protein. **P0** is an immunoglobulin-like membrane protein of Schwann cells of the peripheral nervous system; it is associated with a hereditary polyneuropathy (Charcot–Marie–Tooth disease type 1b). **Myelin proteolipid protein** (PLP or **lipophilin**) is the major myelin protein from the CNS, playing an important role in the formation, or maintenance, of the multilamellar structure of myelin; it is an integral membrane protein. Alternative splicing leads to a shorter variant. Mutations are associated with Pelizaeus–Merzbacher disease, and other mutations result in dysmyelination, e.g. *jimpy* and *rumpshaker* (mouse), and MD (rat). See also **Folch–Lees protein**, **Wolffgram proteolipid protein**.

myelin-proteolipid O-palmitoyltransferase EC 2.3.1.100; *other names*: myelin PLP acyltransferase; acyl-protein synthase; an enzyme that catalyses a reaction between palmitoyl-CoA and [myelin proteolipid] to form [myelin proteolipid] O-palmitoylprotein and CoA.

myelin sheath the sheath that surrounds the axons of vertebrate nerves. It is formed by Schwann cells in peripheral nerves and by oligodendrocytes in the central nervous system; these cells wrap up to 100 concentric layers of their plasma membrane in a tight spiral around the axons. Myelin sheaths prevent almost all electric current leakage across the covered portion of the axon membrane, thereby contributing to the rapid transmission of nerve impulses along the axons. See also **myelin**, **myelin protein**.

myelo+ or (before a vowel) **myel+** *comb. form* **1** denoting bone marrow. **2** denoting the spinal cord. **3** denoting **myelin**.

myeloblast a cell of the bone marrow that is the precursor of the **myelocyte**.

myelocyte a nucleated cell of the bone marrow that is a precursor of the **granulocytes** of the blood.

myeloid 1 of or pertaining to bone marrow. **2** of or pertaining to the spinal cord. **3** of or resembling myelocytes.

myeloma or **myelomatosis** a tumour caused by the uncontrolled proliferation of a clone of immunoglobulin-producing plasma cells. It leads to multiple deposits of tumour cells in the bone marrow and an excessive production of a single type of (i.e. monoclonal) immunoglobulin molecule, which may belong to any of the major classes of immunoglobulins. In some cases either the light or the

heavy chains may be produced in excess or exclusively. *See also* **Bence-Jones protein**, **Waldenström's macroglobulinemia**.

myeloma protein an immunoglobulin that is overproduced by a **myeloma**. They are single immunoglobulin types and form the basis of monoclonal antibody technology. Human examples include **Bence-Jones protein**. *See also* **hybridoma**.

myeloperoxidase a special name for **peroxidase** (def. 2), so named following its isolation from the blood of patients with myeloid leukemia, and originally named **verdoperoxidase** on account of its green colour. It is present in phagosomes of neutrophils and monocytes, where it catalyses the reaction:

The reaction product is strongly bactericidal. The enzyme is a heterotetramer of two α subunits (59 kDa) linked by disulfide bonds, and two β subunits (13 kDa). Each α subunit contains a heme group and a Ca^{2+} -binding region. Both subunits are derived from the same precursor. Several isozymes are produced by alternative splicing. Myeloperoxidase deficiency, resulting from mutation in the gene at 17q22, is not rare. It is frequently asymptomatic but may be accompanied by repeated infection.

Mylar the proprietary name for a type of polyethylene terephthalate polyester that forms very strong films of good transparency and high electrical resistance.

myo+ or (before a vowel) **my+** comb. form denoting muscle.

myo- prefix used to distinguish common **inositol**, 1,2,3,5/4,6-cyclohexanehexol (formerly *meso*-inositol), from the other eight possible inositol stereoisomers.

myoadenylate deaminase *see* **adenylate deaminase**.

myoblast any of the mononucleate precursor cells that fuse to form a multinucleate skeletal muscle cell.

myocardin a transcription factor expressed exclusively in myocardium after birth.

myocardium the middle, muscular, layer of the heart wall. —**myocardial** *adj.*

myocilin or **TIGR** a protein (504 amino acids) expressed in many tissues but having no known function. It contains an N-terminal hydrophobic region, a leucine zipper region, and a region of homology with myosin heavy chain. Mutations in the gene at 1q23 are responsible for autosomal dominant open-angle glaucoma.

myocyte 1 a muscle cell of any type. **2** any contractile cell.

myocyte enhancement factor *abbr.*: MEF; a transcription factor that binds an AT-rich DNA sequence in the promoter region of many muscle-specific genes. There are at least four MEF genes in vertebrates, which are nearly identical in coding N-terminal regions that serve for dimerization and DNA binding.

myoD the gene for myoblast determination protein, a basic helix-loop-helix transcription factor related to **MYC**; the human equivalent is **MYF3**. It is expressed after **myogenin**.

myofibre or (*esp. US*) **myofiber** a skeletal muscle fibre; it consists of a single, long, multinucleate cell, composed predominantly of a large number of myofibrils (typically 1000 or more).

myofibril any of the long, cylindrical, contractile elements, 1–2 μm in diameter, that comprise the major component of the cytoplasm of the **myofibre** and extend for its entire length. Each myofibril is composed in turn of numerous **myofilaments**. —**microfibrillar** *adj.*

myofilament either of two kinds of thin, contractile, threadlike, interdigitating structures within the myofibrils of **striated muscle**. The so-called thick filaments are about 15 nm in diameter and 1.6 μm in length, and the so-called thin filaments are about 8 nm in diameter and 1.0 μm in length.

myogen a name sometimes used for a number of different protein mixtures extractable with water from skeletal muscle of various species of animal. **Myogen A** is a crystallizable complex of **aldolase** and **glycerol-3-phosphate dehydrogenase** that can be prepared from rabbit muscle.

myogenic factor any of various proteins involved in muscle differentiation. They are normally produced only in muscle cells, but have been shown to activate muscle differentiation mechanisms when introduced into other cells. They include MyoD (*see* **myoD**), Myf5, and **myogenin**.

myogenin a protein involved in muscle differentiation (i.e., a **myo-**

genic factor) that induces fibroblasts to differentiate into myoblasts. It is probably a sequence-specific DNA-binding protein, similar to other members of the Myc family of **helix-turn-helix** transcription factors (*see* **MYC**).

myoglobin or (formerly) **muscle hemoglobin** or **myohemoglobin** *abbr.*: Mb; a 17.5 kDa oxygen-carrying hemoprotein that occurs in muscle, particularly in red fibres, and consists of a single polypeptide chain of 153 amino-acid residues, to which a single ferroheme prosthetic group is non-covalently bound. Myoglobin binds dioxygen non-cooperatively, with an affinity between that of hemoglobin and of cytochrome oxidase. It can thus accept dioxygen from hemoglobin, and store it in the muscle cell for release to cytochrome oxidase when the supply becomes limiting. It also assists the direct transfer of dioxygen from the surface of the myocyte to the mitochondria. Sperm-whale myoglobin was the first protein whose 3-D structure was determined by X-ray crystallography.

myoglobinuria the excretion of myoglobin in the urine.

myohaematin a historical term, used by MacMunn for the 'histohaematin' (i.e. the cytochromes) of striated muscle.

myo-inositol an alternative name for **inositol** (def. 1) (formerly known as **muscle sugar**). *See also* **myo-**.

1D-myoinositol-trisphosphate 3-kinase EC 2.7.1.127; an enzyme that catalyses a reaction between ATP and 1D-myoinositol 1,4,5-trisphosphate to form 1D-myoinositol 1,3,4,5-tetrakisphosphate with release of ADP. The enzyme requires calcium. *See also* **inositol phosphates**.

myokinase an alternative name for **adenylate kinase**.

MyoR *see* **capsulin**.

myosin any of a group of related proteins with ATPase activity that occur in the contractile apparatus of both muscle and non-muscle cells; the myosin of striated muscle is the major component of the thick filaments. Individual myosin molecules consist of two identical **heavy chains** of ~200 kDa and two pairs of light chains (*see* **light chain** (def. 2)) with distinct masses that vary within the range 15–27 kDa according to the source. The N-terminal region of each heavy chain consists of a globular head with which the light chains are associated; the remaining three-quarters of each heavy chain consists predominantly of an alpha helix, which intertwines with its partner to form a long tail. The head region contains binding sites for actin and for ATP, while aggregation with other myosin molecules to form filaments occurs at the tail region. For example, human muscle protein is a hexamer of two heavy chains and four light chains. Different isoforms exist for different muscle types. Light chain 1, the skeletal muscle isoform, contains an **EF hand** motif. Some early preparations of myosin were denoted by letters. Thus, myosin A and myosin B were actin-poor and actin-rich preparations respectively, while myosin T and L-myosin were among the first actin-free preparations. The name myosin was originally given by F. W. Kühne, in 1859, to the substance in muscle press juice that, on standing at room temperature, set to a gel.

myosin-binding C protein a protein that is arranged transversely in seven to nine strips in the A bands of muscle **sarcomeres**. It binds the coiled-coil portion of myosin heavy chains to titin. A gene at 11p11.2 encodes the cardiac isoform, a protein of ~1200 amino acids that contains immunoglobulin-like and fibronectin repeats. Various mutations cause hypertrophic cardiomyopathy.

myosin-heavy-chain kinase EC 2.7.1.129; an enzyme that catalyses the phosphorylation by ATP of specific threonines of myosin heavy chain with release of ADP, during chemotaxis of *Dictyostelium discoideum* (slime mould). It inhibits myosin thick filament formation.

myosin-light-chain kinase EC 2.7.1.117; *other names*: myosin kinase; smooth-muscle-myosin-light-chain kinase; an enzyme that catalyses the phosphorylation by ATP of myosin light chain with release of ADP. It was one of the first Ca^{2+} /calmodulin-dependent protein kinases to be discovered. Its specificity is restricted to myosin light chain. In skeletal muscle, light-chain phosphorylation modulates tension during contraction. In smooth muscle, it initiates contraction.

myosin-light-chain-phosphatase EC 3.1.3.53; *other names*: myosin light chain kinase phosphatase; myosin phosphatase; an en-

zyme that catalyses the hydrolysis of phosphate from myosin light-chain phosphate.

myostatin a protein of the transforming growth factor β superfamily that is expressed in cells of skeletal muscle lineage. Gene knockout in mice, and deficiency in cattle, cause dramatic and widespread increase in skeletal muscle mass. Overexpression or prolonged injection in mice lead to severe loss of muscle and adipose tissue. Myostatins from many vertebrate species have an identical, biologically active C-terminal region. Mutations in cattle produce double-muscling.

myotonia any genetically distinct hereditary disease characterized by muscle hyperexcitability, hypertrophy, and stiffness. Myotonia congenita results from numerous mutations in the gene for the sarcolemmal voltage-gated chloride channel, which normally forms multimeric subunits each of which contains ≈ 13 transmembrane segments.

myotonia congenita *see* **myotonia**.

myotonic dystrophy a common hereditary muscular dystrophy in which muscle wasting and weakness (i.e. dystrophy) are associated with stiffness (i.e. myotonia). Type 1 is due to expansion of a CTG trinucleotide repeat in the 3' untranslated region of the gene (at 19q13.2) for muscular dystrophy protein kinase. Type 2 is due to expansion of a CCTG tetranucleotide repeat in intron 1 of the gene (at 3q21) for **ZNF9**.

myotonic dystrophy protein kinase a cytosolic protein-serine/threonine kinase found predominantly in heart, skeletal muscle, brain, and eye. The gene at 19q13.2-q13.3 encodes a protein of 585 amino acids. In persons affected by myotonic dystrophy type 1, the 3' untranslated region contains 50 to several thousand repeats of the trinucleotide CTG. Normal subjects have less than 37 such repeats, whereas healthy genetic carriers of the disorder have 50 to 100 repeats.

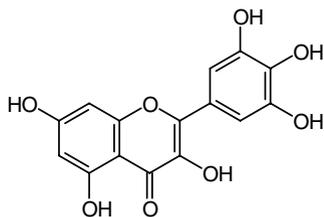

myotrophin a 12 kDa protein of hypertrophied myocardium of spontaneously hypertensive rats that stimulates protein synthesis in cultured adult rat myocytes *in vitro*. It contains **ankyrin** repeats, and binds to **NF- λ B**.

myotube the multinucleate structure formed by the fusion of proliferating myoblasts in culture under certain conditions. It is characterized by the presence of certain muscle-specific proteins that are not found in the myoblast and may represent a stage in the development of skeletal muscle cells.

myotubularin a protein encoded by a gene at Xq28, mutations of which cause X-chromosome-linked myotubular myopathy. The protein contains ≈ 621 amino acids, which include a sequence that corresponds exactly with the consensus sequence for tyrosine phosphatases. It is expressed in skeletal muscle and testes, but not in fetal tissues (e.g. brain, liver, kidney).

Myr *symbol for the myristoyl group*.

myricetin 3,3',4',5,5',7-hexahydroxyflavone; a **flavone** that is widely distributed in plants. The name originates from *Myrica*, a genus of shrubs. Myricetin inhibits a number of enzymes, including α -glucosidase, xanthine oxidase, and glyoxalase.

myricyl or **melissyl** the common name for triacontyl,

$\text{CH}_3\text{--}[\text{CH}_2]_{28}\text{--CH}_2\text{--}$, the alkyl group derived from the C_{30} straight-chain alkane, triacontane. Myricyl palmitate is the major component of beeswax.

myristate **1** the trivial name for tetradecanoate, $\text{CH}_3\text{--}[\text{CH}_2]_{12}\text{--COO}^-$, the anion derived from myristic acid (i.e. tetradecanoic acid), a saturated straight-chain higher fatty acid and a major component of many plant and animal fats. **2** any mixture of free myristic acid and its anion. **3** any salt or ester of myristic acid.

myristin an old name for any of the glyceryl esters of myristic acid, especially the triester, **trimyristin**, or trimyristoylglycerol.

myristoleic acid *see* **tetradecenoic acid**.

myristoyl or (formerly) **myristyl** *symbol*: Myr; the trivial name for tetradecanoyl, $\text{CH}_3\text{--}[\text{CH}_2]_{12}\text{--CO--}$, the acyl group derived from myristic acid (i.e. tetradecanoic acid). It occurs in most animal and plant fats and oils as acylglycerols and in phospholipids. The oils of the seeds of nutmeg (*Myristica fragrans*) and other members of the Myristicaceae are particularly rich sources. *Compare* **myristyl**.

myristoylation the introduction of one or more **myristoyl** groups into an organic compound. Protein *N*-myristoylation refers to the covalent attachment of a **myristoyl** group via an amide bond to the N-terminal Gly residue of a nascent polypeptide. This **post-translational modification** has only been observed in eukaryotes and is irreversible. The *N*-myristoyl proteins are numerous with diverse functions. In some cases the modification is essential for the biological role of the protein, while in other cases it is not essential. The process is catalysed by glycylpeptide *N*-tetradecanoyltransferase (EC 2.3.1.97).

myristyl **1** the common name for tetradecyl, $\text{CH}_3\text{--}[\text{CH}_2]_{12}\text{--CH}_2\text{--}$, the alkyl group derived from tetradecane; use deprecated. **2** a former trivial name for tetradecanoyl (**myristoyl** now used).

myrosinase an alternative name for **thioglucosidase**.

MySQL *see* **relational database management system**.

myt5 the gene for bacteriophage T5 5'-exodeoxynuclease (EC 3.1.11.3). It performs exonucleolytic cleavage in the 5' to 3' direction to yield 5'-phosphomononucleotides. *See also* **deoxyribonuclease**.

myxamoeba or (esp. US) **myxameba** a free-living haploid amoeboid cell occurring in the life cycles of the cellular slime moulds and the myxomycetes. In the former they aggregate to form a slug and in the latter a plasmodium.

myxedema or (esp. Brit.) **myxoedema** the syndrome caused by hypothyroidism in adults. It is characterized by mucoid infiltration and coarsening of the skin, weight gain, intolerance to cold, and mental sluggishness.

myxo+ or (usually before a vowel) **myx+** *comb. form* indicating mucoid, mucus, or slime.

Myxobacterales the myxobacteria; an order of Gram-negative bacteria that bear extracellular slime and have a characteristic swarming habit that leads to the formation of stalked fruiting bodies. A more recent classification has suggested replacement of Myxobacterales by Myxococcales.

myxobacteria bacteria belonging to the order **Myxobacterales**.

myxoedema a variant spelling (esp. Brit.) of **myxedema**.

myxomatosis a highly contagious disease of rabbits, caused by a myxoma virus, part of a subgenus of poxvirus. It is characterized by proliferative changes in the connective tissues.

Myxomycetes a large class of very primitive organisms, also known as the true or acellular slime moulds, found living saprophytically in damp conditions. Their major vegetative stage is a multinucleate migratory mass of protoplasm, from which (usually macroscopic) fruiting bodies arise.

myxothiazol an inhibitor of complex III of the mitochondrial electron transport chain, used as an antifungal agent.

myxovirus any of a group of negative-strand RNA animal viruses, now divided into **orthomyxoviruses** and **paramyxoviruses**.

Nn

n symbol for 1 nano+ (SI prefix denoting 10^{-9} times). 2 neutron; may be written as n^0 to indicate its charge.

n symbol for 1 any (unknown or unspecified) number, especially an integer. 2 amount of substance; the substance in question may be indicated as a suffix in parentheses or by a subscript. 3 refractive index (of a nonabsorbing material); n_D symbol for refractive index measured with light of the sodium D-lines (589.0 and 589.5 nm). 4 order of reaction. 5 order of reflection. 6 haploid number of chromosomes. 7 number density.

n- prefix indicating normal (isomer); no longer used.

n_H symbol for Hill coefficient (alternative to *h*).

N symbol for 1 nitrogen. 2 newton. 3 a residue of the α -amino acid L-asparagine (alternative to Asn). 4 a residue of an incompletely specified base in a nucleic-acid sequence that may be adenine, cytosine, guanine, or either thymine (in DNA) or uracil (in RNA). 5 an undertermined, unidentified, or unspecified nucleoside residue (alternative to Nuc). 6 (when suffixed to the symbol for a sugar molecule or residue) aminodeoxy+; e.g. GlcN is the symbol for 2-amino-2-deoxy-D-glucose (i.e. D-glucosamine). 7 normal (def. 1).

N symbol for 1 the SI derived physical quantity named number of entities (e.g. molecules, atoms, ions, formula units). 2 neutron number. 3 Avogadro constant (N_A or L now recommended). 4 the total number of receptors per unit area of membrane, per cell, or per unit mass of protein.

N- prefix (in chemical nomenclature) indicating substitution on nitrogen; a particular nitrogen atom may be specified by a right superscript.

N_A symbol for Avogadro constant (alternative to *L*).

N_L symbol for Loschmidt constant.

Na symbol for sodium.

NA abbr. for 1 nicotinic acid. 2 noradrenaline (i.e. norepinephrine). 3 nucleic acid. 4 numerical aperture.

NAA abbr. for *N*-acetylaspartate.

NAADP abbr. for nicotinic acid adenine dinucleotide phosphate; the form of NADP in which the nicotinamide moiety has been exchanged for nicotinic acid in a reaction catalysed by ADP-ribosyltransferase. In sea urchin eggs, plant cells, and some mammalian tissues – e.g. brain (especially medulla, thalamus, and midbrain), pancreatic acini, and heart – it mobilizes intracellular Ca^{2+} stores via receptors that are distinct from, but which interact with, those for inositol trisphosphate and for ryanodine/cyclic ADP-ribose. It is rapidly degraded within the aforementioned cells.

NAC symbol for (when suffixed to the symbol for a sugar molecule or residue) an acetylated aminodeoxy sugar; e.g. GlcNAc is the symbol for *N*-acetylglucosamine or 2-acetamido-2-deoxy-D-glucose.

NAC abbr. for nascent chain-associated complex; a dimer of α (33 kDa) and β (22 kDa) subunits that associates with nascent polypeptide chains and their ribosomes, and dissociates from both after chain release from the ribosome. It is present in eukaryotic cytosol and lacks peptidylprolyl isomerase activity. See trigger factor.

nactin any of a group of macrotetrolide antibiotics produced by various strains of *Actinomyces*. The group includes nonactin, monactin, dinactin, and trinactin.

NAD abbr. for nicotinamide-adenine dinucleotide (when its oxidation state is unknown or unspecified). Besides being a coenzyme, NAD is a precursor of NADP, of mono- and poly-ADP-ribosylation of some proteins, and of cADP-ribose. See also **NAD⁺**, **NADH**, **NADP**, **NAD(P)**.

NAD⁺ abbr. for oxidized nicotinamide-adenine dinucleotide. The positive charge refers to the nicotinamide ring; the overall charge is negative, owing to the two phosphate groups, which are negatively charged at neutral pH.

NAD⁺ ADP-ribosyltransferase see poly(ADP)-ribosyl transferase.

NADH abbr. for nicotinamide-adenine dinucleotide (reduced). The corresponding oxidized state is **NAD⁺**.

NADH₂ alternative name for nicotinamide-adenine dinucleotide (reduced), the oxidized form being NAD. NADH is preferred except in cases where the use of the charge on **NAD⁺** would be misleading.

NADH dehydrogenase EC 1.6.99.3; systematic name: NADH:(acceptor) oxidoreductase; other names: cytochrome *c* reductase; type I dehydrogenase. An enzyme, associated with a respiratory chain, that catalyses a reaction between NADH and an acceptor to form **NAD⁺** and a reduced acceptor; FMN or, in plant mitochondrion, FAD, is a prosthetic group.

NADH dehydrogenase (ubiquinone) EC 1.6.5.3; other names: ubiquinone reductase; type I dehydrogenase; complex I dehydrogenase; a flavoprotein enzyme that catalyses the reaction:

The flavin is FMN, and the complex also contains at least nine iron-sulfur proteins. This is the catalytic activity of mitochondrial complex I.

NADH kinase EC 2.7.1.86; an enzyme that catalyses the formation of NADPH from ATP and NADH with release of ADP.

Nadi reagent a mixture of 1-naphthol and *N,N*-dimethyl-*p*-phenylene diamine that can be oxidized by cytochrome oxidase to form indophenol blue.

NAD⁺ kinase EC 2.7.1.23; an enzyme that catalyses the formation of **NADP⁺** from ATP and **NAD⁺** with release of ADP.

NADP abbr. for nicotinamide-adenine dinucleotide phosphate (when its oxidation state is unknown or unspecified). Besides being a coenzyme, NADP is a precursor of NADP. See also **NAD**, **NADP⁺**, **NAD(P)**, **NADPH**.

NADP⁺ abbr. for oxidized nicotinamide-adenine dinucleotide. The positive charge refers to the nicotinamide ring; the overall charge is negative, owing to the two phosphate groups, which are negatively charged at neutral pH.

NAD(P) abbr. for a coenzyme that may be NAD or NADP.

NAD(P)⁺ abbr. for a coenzyme that may be **NAD⁺** or **NADP⁺**.

NAD(P)⁺-arginine ADP-ribosyltransferase EC 2.4.2.31; other names: ADP-ribosyltransferase; mono(ADP-ribosyl) transferase; a sarcoplasmic reticulum enzyme that catalyses the formation of *N*²-(ADP-D-ribosyl)-L-arginine from **NAD⁺** and L-arginine with release of nicotinamide. It couples poly(ADP-ribose) to arginine residues in proteins.

NADPH abbr. for nicotinamide-adenine dinucleotide phosphate (reduced). The corresponding oxidized state is **NADP⁺**.

NADPH₂ alternative name for nicotinamide-adenine dinucleotide phosphate (reduced), the oxidized form being NADP. NADPH is preferred except in cases where the use of the charge on **NADP⁺** would be misleading.

NAD(P)H abbr. for a coenzyme that may be either NADH or NADPH. Use of **NAD(P)H₂** to represent **NAD(P)H** is not recommended.

NADPH:adrenodoxin oxidoreductase EC 1.18.1.2; other names: adrenodoxin reductase; recommended name: ferredoxin-NADP⁺ reductase; a flavoprotein enzyme that catalyses the reaction:

The flavin is FAD.

NAD(P)⁺ stereospecificity in oxidation-reduction reactions involving the nicotinamide coenzymes, **NAD⁺** and **NADP⁺** reversibly accept hydrogen at the 4 position of the nicotinamide ring. In NADH and NADPH this position is **prochiral**, and the faces of the nicotinamide ring and the *c*-4 hydrogens of the dihydronicotinamide ring may be labelled according to the *Re/Si* and *pro-R/pro-S* conventions, respectively. Then, if the ring is drawn with the $-\text{CONH}_2$ group pointing to the right, the hydrogen projecting out from the plane of the paper is the *pro-R* hydrogen (or H_R) and that projecting back the *pro-S* hydrogen (or H_S). Alcohol dehydrogenases (EC 1.1.1.1) transfer to the *Re* face (i.e. that from which H_R

points out) and use H_R . In biochemistry the *pro-R* hydrogen region is also labelled as H_A , and the *pro-S* hydrogen as H_B . Enzymes that use the *pro-R* hydrogen (H_A) are described as A-specific, while those that use the *pro-S* hydrogen (H_B) are called B-specific. See also *pro-R/pro-S* convention, *Re/Si* convention.

NAD(P)⁺ transhydrogenase (AB-specific) EC 1.6.1.2; *other names*: pyridine nucleotide transhydrogenase; transhydrogenase. An enzyme that catalyses the same reaction as **NAD(P)⁺ transhydrogenase (B-specific)**; however, preparations from heart mitochondria are A-specific with respect to NAD⁺ and B-specific with respect to NADP⁺. See also **NAD(P)⁺ stereospecificity**.

NAD(P)⁺ transhydrogenase (B-specific) EC 1.6.1.1; *other names*: pyridine nucleotide transhydrogenase; nicotinamide nucleotide transhydrogenase; a flavoprotein enzyme that catalyses the reaction

(with specificity for H_B of NADPH and NADH). The flavin is FAD. The enzyme is coupled to respiration and acts as a **hydrogen-ion pump**. See also **NAD(P)⁺ stereospecificity**.

NAD⁺ pyrophosphorylase see **nicotinamide-nucleotide adenyltransferase**.

NAD⁺ synthase EC 6.3.1.5; *other name*: NAD⁺ synthetase; an enzyme that catalyses the formation of NAD⁺ from deamido-NAD⁺, ATP, and NH₃ with release of AMP and pyrophosphate. See also **NAD⁺ synthase (glutamine-hydrolysing)**; **nicotinamide-nucleotide adenyltransferase**.

NAD⁺ synthase (glutamine-hydrolysing) EC 6.3.5.1; *other name*: NAD⁺ synthetase (glutamine-hydrolysing); an enzyme that catalyses the formation of NAD⁺ from deamido-NAD⁺, L-glutamine, ATP, and H₂O with release of AMP, pyrophosphate, and L-glutamate. See also **nicotinamide-nucleotide adenyltransferase**.

NaeI a type 2 **restriction endonuclease** recognition sequence: GCC↑GGC.

NAF *abbr.* for Neu-activating factor (see **neu**).

NAG *abbr.* for **1** *N*-acetylglucosamine. **2** (*esp. in clinical chemistry*) *N*-acetylglucosaminidase; see **β-N-acetylhexosaminidase**.

NAGA *abbr.* for *N*-acetylgalactosamine.

Nagarse (proteinase) *another name* for a species variant of **subtilisin**, EC 3.4.21.62, from *Bacillus subtilis*; an endopeptidase with a broad spectrum of proteolytic activity.

Nagase a *pseudoacronym* for **β-N-acetylglucosaminidase** (formerly EC 3.2.1.30). This enzyme is now included with EC 3.2.1.52, **β-N-acetylhexosaminidase**.

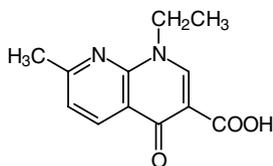

NAIBS *abbr.* for nonadrenergic imidazoline binding site; see **imidazoline receptors**.

Na⁺/I⁻ symporter (*abbr.*: NIS) *an alternative name* for **iodide pump**.

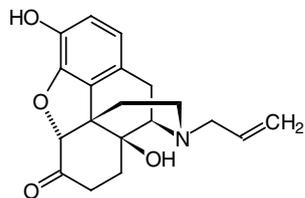

Naka *an alternative name* for **CD36**.

Na⁺,K⁺-ATPase see **sodium/potassium ATPase**.

nalidixic acid 1-ethyl-7-methyl-1,8-naphthyridin-4-one-3-carboxylic acid; a synthetic **4-quinolone antibiotic** that is active against many Gram-negative bacteria. It specifically inhibits bacterial DNA gyrase thereby interfering with DNA synthesis. It has no apparent effect on eukaryotic DNA synthesis.

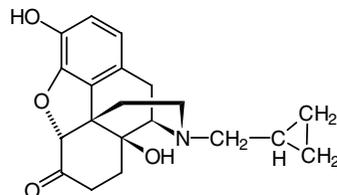

naloxone 1-*N*-allyl-7,8-dihydro-14-hydroxynormorphinone; one of the most effective opiate antagonists. It binds tightly to opiate receptors in the nervous system, its action depending on the 3-carbon side-chain substitution on the nitrogen. It is used as an antidote to overdose of narcotics.

naloxone

naltrexone 1-*N*-cyclopropylmethyl-7,8-dihydro-14-hydroxynormorphinone; the cyclopropylmethyl analogue of **naloxone**; it has similar properties but is longer acting.

NANA *abbr.* for *N*-acetylneuraminic acid (i.e. **sialic acid**).

nano+ *symbol*: n; SI prefix denoting 10⁻⁹ times. It was formerly known as millimicro (*symbol*: mμ).

nanogram *symbol*: ng; a unit of mass equal to 10⁻⁹ gram, or 10⁻¹² kilogram.

nanometre or (*US*) **nanometer** *symbol*: nm; a unit of length equal to 10⁻⁹ metre. It was formerly known as millimicron (*symbol*: mμ).

nanomolar *symbol*: nm or nM; describing a solution containing one **nanomole** per litre of solution, or a specified multiple or fraction thereof; describing an amount-of-substance concentration similarly expressed.

nanomole *symbol*: nmol; a unit of amount of substance equal to 10⁻⁹ mole.

Nanos an RNA-binding protein of *Drosophila* that, with **Pumilio**, keeps mRNA for Hunchback and cyclin B translationally repressed in the posterior thoracic region of the early syncytial embryo.

nanosecond *symbol*: ns; a unit of time equal to 10⁻⁹ second.

nanotechnology the creation and control of objects on nanometre scales. –**nanotechnology** *adj.* –**nanotechnologist** *n*.

NAP1 *abbr.* for nuclear assembly protein 1; a protein (≈12.5 kDa), widely distributed among eukaryotes, that is responsible for chaperoning histones H2A and H2B to DNA during DNA replication. See also **CAF1**.

NAP-2 *abbr.* for neutrophil activating peptide 2; one of several peptides derived from **platelet basic protein precursor**. It consists of **LA-PF4** without the first 15 N-terminal amino acids. It is a potent chemoattractant and activator for neutrophils.

NAP cell adhesion a cell adhesion system comprising nectin, afadin, ponsin, and possibly other proteins. It occurs in **adherens junctions** and **tight junctions**.

Naphthalene Black or **Naphthol Blue Black** or **Amido Black** a dye used for staining protein on cellulose acetate or on starch or agarose gels.

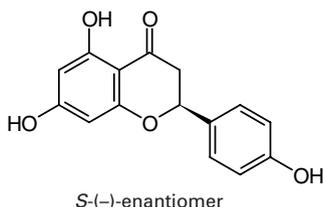

Naphthol Blue Black an alternative name for **Naphthalene Black**.

Napierian logarithm *symbol:* \log_e or \ln ; an alternative name for natural logarithm. [After John Napier (1550–1617), Scots mathematician who invented logarithms.]

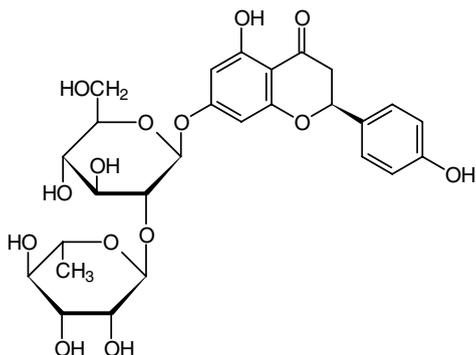

narcosis a state of partial or complete loss of consciousness induced by a drug or drugs that have a depressant action on the central nervous system.

narcotic 1 any of a heterogeneous group of drugs that is capable of inducing narcosis and noted for their analgesic action. **2** (*esp. US*) the trivial name for any illegal drug or abused drug. **3** of, or relating to, narcosis; of, relating to, or denoting a narcotic drug.

naringenin 4',5,7-trihydroxyflavanone; the aglycon of **naringin**, and an inducer of *nod* genes in some *Rhizobium* species.

naringin naringenin-7-rhamnoglucoside; a compound that occurs in the flowers, fruit, and rind of the grapefruit, and is the main bitter component of grapefruit juice. *See also* **naringenin**.

NARP *abbr. for* neuropathy, ataxia, and retinitis pigmentosa; a mitochondrial disease that includes developmental delay, retinitis pigmentosa, ataxia, and other neurological symptoms. It is associated with two point mutations in the mitochondrial gene for a subunit of F_0F_1 ATPase.

NAS *abbr. for* nonsense-mediated alternative splicing.

nascent just formed or in the process of being formed, especially in a chemical or biochemical reaction.

nascent chain-associated complex *see* **NAC**.

native (*of a biopolymer*) undenatured, i.e. having the structure and biological activity possessed in living material.

native state of a protein or nucleic acid, the form in which it occurs in the intact cell, its three-dimensional structure depending on formation of the appropriate hydrogen bonds.

natriuresis the excretion of sodium ions in the urine.

natriuretic 1 describing any agent that promotes the excretion of sodium ions in the urine. **2** such an agent.

natriuretic hormone any peptide present in plasma or urine that is capable of stimulating sodium excretion by the kidney and of inhibiting membrane Na^+ , K^+ -ATPase in cells from kidney and some other tissues. *See* **natriuretic peptide**.

natriuretic peptide any of several peptides, secreted by various tissues, that stimulate natriuresis. The first of the group to be identified was **atrial natriuretic peptide** (*or* atrial natriuretic factor) (*abbr.:* ANP; *other name:* type A natriuretic peptide; *former names:* atri-

opeptin; vasoactive peptide). Its discovery arose from the observation that extracts of atrial granules could bring about **natriuresis**. Subsequently, **brain natriuretic peptide** (*abbr.:* BNP; *other name:* type B natriuretic peptide) and **type C natriuretic peptide** (CNP) were identified. Members of this family share many common features; they are produced primarily in the heart and specialized areas of the central nervous system, and induce diuresis, natriuresis, and vasorelaxation. The natriuretic effect results from direct inhibition of sodium absorption in the collecting duct, increased glomerular filtration, and inhibition of aldosterone production and secretion. The major constituent of atrial granules, ANP, is synthesized from a precursor, prepronatriodilatin (152 amino acids), which is cleaved to proANP (126 amino acids). The latter is strikingly similar between many species; proANP is cleaved into an N-terminal fragment, amino-acid residues 1–98, and the biologically active hormone, residues 99–126; the amino-acid sequence of ANP (proANP 99–126) is identical in all mammalian species, except at residue 12 (110 of proANP), which is methionine in humans, dogs, and cows, but isoleucine in rats, mice, and rabbits. There are two genes for the precursor (prepronatriodilatin); cleavage of the latter leads to two peptides, ANP:

SLRRSSFCGGRMDRIGAQSGLGCNSFRY

and cardiodilatin-related peptide (CDP):

NPMYNAVSADLMDFKNLLDHLLEEKMPLED.

The synthesis of BNP follows a similar course. In humans and pig, a 32-amino-acid hormone is the circulating form of BNP, sequence (human)

SPKMQVQSGCFGRKMDRISSSSGLGCKVLRRH;

in rodents BNP contains 45 amino acids and is known as iso-ANP. A 17-member ring, formed by a disulfide bridge between the two cysteine residues, is essential for biological activity of ANP and BNP. *See also* **natriuretic-peptide receptor**.

natriuretic-peptide receptor any type 1 membrane glycoprotein that binds **natriuretic peptides** and mediates their intracellular effects. Three receptors have been identified: ANP_A (previously known as GC-A, ANP-R_1 , or ANP_B); ANP_B (previously known as GC-B); and ANP_C . Human ANP_A and ANP_B each have one transmembrane domain and intrinsic guanylate cyclase activity in an intracellular domain, which is highly conserved (88% identity). At the ANP_A receptor, atrial natriuretic peptide is about ten times more potent than brain natriuretic peptide, whereas type C natriuretic peptide is 50–500 times more potent than other agonists at the ANP_B receptor. ANP_C is a disulfide-linked homodimer with one transmembrane domain and no guanylate cyclase domain; it acts through other second messenger systems.

natural abundance the number of atoms of a given nuclide in any naturally occurring mixture of the nuclides of a particular element, expressed as a percentage or fraction of the total number.

natural killer cell *see* **NK cell**.

natural language processing *abbr.:* NLP; the computational analysis and interpretation of human language. NLP is used in software that provides automatic translations of text from one language to another, in robotic systems that use human-language-type commands, and in text-mining tools (e.g. to provide summaries or abstracts of large volumes of text).

natural logarithm *or* Napierian logarithm *symbol:* \log_e or \ln ; *see* **logarithm**.

natural product any organic substance of biological origin, as opposed to one obtainable only by chemical synthesis. In practice the term is often restricted to mean **secondary metabolite**.

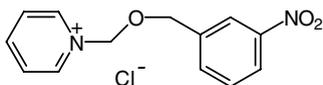

natural selection the principle that the best competitors in any given population of organisms have the best chance of breeding success and thus of transmitting their characteristics to subsequent generations. The members of any population show individual differences – anatomical, physiological, or metabolic – that affect their functional efficiency in a given environment. The less efficient members tend to die out or produce fewer offspring than the more efficient members, which are better adapted to compete for food or other resources, and so produce relatively more offspring. The principle is fundamental to modern concepts of evolution, and was first

articulated, independently, by the British naturalists Alfred Russel Wallace (in 1858) and Charles Darwin (in 1859).

natural-selection theory of immunity or **Jerne's theory of immunity** a theory of antibody production that postulates the spontaneous presence, in the blood of an animal, of small numbers of antibody molecules against all antigens to which the animal can respond, and delegates to the antigen the sole role of carrying such specific globulin molecules from the bloodstream into cells in which these molecules can induce proliferation of a particular antibody.

Nb *symbol for niobium.*

NBPC *abbr. for 1-[(m-nitrobenzyloxy)methyl]pyridinium chloride; a reagent useful for the immobilization of single-stranded nucleic acids on cellulose.*

NBS *abbr. for 1 National Bureau of Standards (of the USA) (now National Institute for Standards and Technology). 2 N-bromosuccinimide.*

NCAM *abbr. for neural cell adhesion molecule.*

NCBI *abbr. for National Center for Biotechnology Information; see bioinformatics institute.*

NCE *abbr. for novel chemical entity.*

N cell a type of cell, found mainly in the upper small intestine in humans, that contains round, homogeneous granules in which **neurotensin** is stored. Such cells are sparse in the lower small intestine.

NC-IUB *abbr. for Nomenclature Committee of the International Union of Biochemistry; redesignated (in 1992) NC-IUBMB.*

NC-IUBMB *abbr. for Nomenclature Committee of the International Union of Biochemistry and Molecular Biology. Compare JCBN.*

NcoI a type 2 **restriction endonuclease**; recognition sequence: C↑CATGG.

NCoR *abbr. for nuclear hormone corepressor; a protein that, with SMRT, causes transcriptional repression by recruiting the histone deacetylase complex Sin 3-HDAC. The NCoR-SMRT dimer binds unliganded retinoic acid and thyroid hormone receptors.*

ncRNA *abbr. for noncoding RNA; strictly, any RNA that is not mRNA, but the term also commonly excludes tRNA and rRNA. The term is used predominantly in relation to eukaryotes, with sRNA (small RNA) being used in relation to prokaryotes. It encompasses many varieties of RNA that have specific, but noncoding, functions. Examples are: miRNA (micro RNA; 21–25 nt), which modulates development in many eukaryotes; sRNA (≈100–200 nt), which are translation regulators in bacteria; 7S RNA (300 nt) of the signal recognition particle; U-snrRNA (100–215 nt), which are involved in spliceosomes in eukaryotes; and RNAs (>10 000 nt) that are involved in gene silencing in higher eukaryotes (see Xist).*

NCS *the proprietary name for a 0.6 m solution in toluene of a mixture of quaternary ammonium compounds of general formula [(CH₃)₂R'R''N]⁺OY⁻, where R' and R'' are unbranched alkyl groups containing 6 to 20 carbon atoms and Y is a hydrogen atom or a lower alkyl group. It is useful for solubilizing a wide range of specimens of biological origin in organic solvents for liquid scintillation counting.*

Nd *symbol for neodymium.*

NdeI a type 2 **restriction endonuclease**; recognition sequence: CATATG.

ndNA *abbr. for nuclear DNA.*

NDP *abbr. for any (unknown or unspecified) nucleoside diphosphate in which the diphosphate moiety is esterified at the 5' position of the glucose.*

Ne *symbol for neon.*

NE *abbr. for norepinephrine.*

nearest-neighbour sequence analysis a technique that employs a 5'-³²P-labelled deoxyribonucleotide substrate in the enzymic synthesis of DNA followed by enzymic degradation of the DNA specifically to 3'-deoxyribonucleotides. From knowledge of the la-

belled substrate used and of the labelled degradation products formed, the **nearest neighbour frequency**, i.e. the frequency with which a particular nucleotide is found next to a specific neighbour nucleotide in the polynucleotide chain, can be calculated.

near ultraviolet radiation **ultraviolet radiation** in the wavelength range 200–400 nm.

nebulette a 107 kDa filamentous protein specific for cardiac muscle. The C-terminal 30 kDa region is integrated in the Z disc, and is highly homologous with that of nebulin. Defects in nebulette can cause cardiomyopathy.

nebulin a giant protein (800 kDa) that is specific for the skeletal muscle of vertebrates; it acts possibly as a 'molecular ruler' for length regulation of the thin filament. The protein appears to have small repeats of approximately 35 amino acids.

nebulize or **nebulise** to convert a liquid into a mist or a spray of fine droplets. —**nebulization** or **nebulisation** *n.*

nebulizer or **nebuliser** a device for nebulizing a liquid (*see nebulize*); an atomizer.

necrobiosis the death of a cell or a group of cells within a tissue, whether a normal occurrence or due to a pathological process.

necropsy *another name for autopsy.*

necrosis the death of a portion of a tissue as a result of disease or injury. The cells swell, their plasma membranes become disrupted, and the cell contents are released into the extracellular space, where they often trigger an inflammatory response. The process is unregulated and should be distinguished from **apoptosis**.

necrotizing encephalopathy *an alternative name for Leigh syndrome.*

nectary a gland that secretes the sugary fluid called nectar. Nectaries occur in many animal-pollinated flowers, to attract insects, birds, and other pollinating agents.

nectin-1 a transmembrane cell-cell adhesion molecule forming part of the **NAP cell adhesion** system in adherens and tight junctions. The nectin-1 gene is mutated in cases of **cleft lip/palate-ectodermal dysplasia syndrome**. It is the main cell surface receptor for alpha-herpesviruses.

Nedd *abbr. for NPC-expressed, developmentally down-regulated genes (NPC is an abbreviation of neural precursor cells). These genes are down-regulated during mouse brain development. The products are proteins presumed to be involved in embryonic development and differentiation of the nervous system. Nedd-2 protein is a cysteine endopeptidase that may be involved in controlling cell death. Nedd-4 is ubiquitously expressed in mammals. It contains multiple WW domains, which bind with great affinity to the β and γ subunits of epithelial Na channel (ENaC), and a ubiquitin-ligase domain. Nedd-8 (called Rub 1 in yeast) is a ubiquitin-like molecule in mammals that becomes conjugated with cullin 1 and promotes its degradation in proteasomes.*

neddylation the process whereby Nedd-8 (or Rub 1 of yeast), a ubiquitin-like protein conjugate to some proteins to target them for degradation by proteasomes or for deneddylation by COP signalosomes. It is important in controlling the auxin response pathway in plants.

Needleman-Wunsch alignment algorithm a dynamic programming algorithm used in sequence alignment that employs a 2D search matrix, such that its speed and storage requirements are of the order $N \times M$ when sequences of length N and M are aligned. The algorithm has large memory requirements owing to its traceback step, where the matches of the optimal alignment are reconstructed, making it too slow for routine database searches. *See alignment algorithm. See also Smith-Waterman alignment algorithm.*

NEFA *abbr. for nonesterified fatty acid. Compare FFA.*

negative 1 (of an electric charge) having the same polarity as an electron. **2** (of a chemical entity) having a negative electric charge; having an excess of electrons. **3** (of a point in an electric circuit) having a lower potential than some other point to which a potential of zero is assigned. **4** (*in photography*) an exposed and developed photographic film or plate showing an image in reversed tones, or complementary colours, to those of the object photographed. **5** a quantity less than zero. —**negativeness** or **negativity** *n.*

negative chromatography *a term sometimes used to denote methods of purification of substances by affinity chromatography in which*

a specific contaminant in a sample interacts with and is selectively retained by the adsorbent, especially as opposed to **positive chromatography**.

negative-contrast technique a technique used in preparing specimens for electron microscopic examination in which the specimen is mixed with an electron-dense material that penetrates the interstices of the specimen but not the material of the specimen itself. The specimen thus appears transparent against an opaque background. It is commonly called **negative staining**.

negative control the prevention of some biological activity caused by the presence of a specific chemical entity.

negative cooperativity a form of **cooperative ligand binding** in which binding of one ligand to one site on a (macro)molecule decreases the affinity at other sites for the subsequent binding of other ligands.

negative effector *see* **effector**.

negative elongation factor *see* **NELF**.

negative feedback *see* **feedback** (def. 1).

negative-ion mass spectrometry a version of **mass spectrometry** in which negative rather than positive ions, generated from the sample by chemical ionization, are separated and measured in an appropriate instrument.

negative staining *see* **negative-contrast technique**.

negative strand *another name for* **minus strand** (def. 2); in some RNA viruses, RNA is a minus strand which does not directly code for protein. Such viruses have a replicase packaged into the capsid to enable them to synthesize the plus strands necessary for replication.

negative-strand virus *or* **negative-stranded virus** any RNA virus in which the genome consists of single-stranded RNA (i.e. minus strand) of base sequence complementary to that of the virus-specified mRNA (which is the positive, or plus, strand). Such viruses, which comprise class V in the **Baltimore classification**, must make a positive RNA strand before making viral proteins. *See also* **minus strand** (def. 2), **plus strand** (def. 2).

neighbour-joining a method for inferring phylogenetic trees based on the principle of **minimum evolution**. The method resolves the phylogeny in a stepwise fashion by selectively joining pairs of taxa that minimize the sum of branch lengths. Neighbour joining is computationally efficient and is an appropriate reconstruction approach where evolution has not proceeded in a strictly clocklike manner.

NELF *abbr. for* negative elongation factor; a protein complex that inhibits transcriptional elongation by binding to RNA polymerase. It consists of five subunits (NELF-A to NELF-E). NELF-A (66 kDa, 528 amino acids) and shares 21% sequence identity with hepatitis delta antigen (HDAg-S). NELF-E (46 kDa) is identical with a putative RNA-binding protein.

NEM *abbr. for* 1 *N*-ethylmaleimide. 2 nemaline myopathy.

nemaline myopathy *abbr.:* NEM; a slowly progressing myopathy characterized by rodlike structures, composed largely of α -actinin and actin, in skeletal muscle fibres. Nem1 (gene locus at 1q22-q23) is an autosomal dominant disease and is associated with a missense mutation in α -tropomyosin. NEM2 (gene locus at 2q22) is an autosomal recessive disease whose gene locus is that for nebulin.

nematic (of a substance) being in or having a mesophilic state in which the molecules are arranged as in a series of parallel threads but not in layers. The molecules can rotate about their axes and can move in the plane orthogonal to the line of the thread. *Compare* **smectic**. *See also* **liquid crystal**.

Nembutal *a proprietary name for* pentobarbitone sodium; pentobarbital sodium.

NEMO *abbr. for* nuclear factor κ B essential modulator; a 48 kDa zinc finger protein that is the regulatory subunit of the I κ B kinase complex, which is essential for NF- κ B signalling.

N-end rule a rule stating that the *in vivo* half-life of a protein is a function of its N-terminal residues.

neo *abbr. for* neomycin.

neo+ *comb. form* 1 denoting new, recent. 2 (*in chemistry*) denoting an isomer of new (and therefore initially unknown) structure.

neo^R *abbr. for* neomycin resistance.

neo-Darwinism the reworking of evolutionary theory in the light of

discoveries about genetics as a result of the work of Fisher, Haldane, Sewall Wright, and others. The behaviour of genes in natural populations is understood in terms of the four fundamental evolutionary forces: **natural selection**, **genetic drift**, gene flow, and **mutations**.

neoendorphin any of a small group of [Leu⁵]enkephalin-related peptides. α Neendorphin is the decapeptide [Leu⁵]enkephalinyll-Arg-Lys-Tyr-Pro-Lys, and β neendorphin is the nonapeptide [Leu⁵]enkephalinyll-Arg-Lys-Tyr-Pro; both are hypothalamic opioid peptides. *See also* **proenkephalin**.

neoflavone any of a group of 4-phenyl-1,2-benzopyrones found in certain plants. Their occurrence is probably restricted to the Guttiferae and Leguminosae. —**neoflavonoid** *n*.

neoglycoprotein *a generic name for* any originally carbohydrate-free protein that has been chemically derivatized by covalent attachment of carbohydrate.

neokestose *O*- β -D-fructofuranosyl-(2 \rightarrow 6)- α -D-glucopyranosyl- β -D-fructofuranoside; an isomer of **kestose** isolated from the sap of the sugar maple and produced artificially, together with kestose, by the action of yeast or mould invertase preparations on sucrose.

neolignan any of a class of phenylpropanoid dimers in which the phenylpropane units are linked head-to-tail instead of tail-to-tail as in **lignans**; e.g. eusiderin from the heartwood of members of the Magnoliaceae.

neomycin an aminocyclitol antibiotic complex produced by *Streptomyces fradiae*. It consists of: neomycin A (*or* **neamine**; a degradation product of neomycin B and neomycin C), neomycin B, and neomycin C. Neomycin causes misreading during protein synthesis in bacteria but its target site on the ribosome is apparently different from that of streptomycin. **Neomycin resistance** is conferred by the enzyme aminoglycoside 3'-phosphotransferase. *See also* **neosamine C**.

neonatal of, relating to, or affecting a newborn animal. For human infants the neonatal period is considered to be the first month after birth.

neonatal jaundice a physiological predominantly unconjugated hyperbilirubinemia with clinical jaundice, affecting about half of all human neonates during the first five days of life. It results from increased bilirubin production and delayed maturation of liver **UDP-glucuronosyltransferase** activity. Maternal-fetal Rh blood group incompatibility and hereditary hyperbilirubinemia syndromes exaggerate the condition, which, if untreated, can lead to kernicterus and brain damage.

neonate any newborn animal.

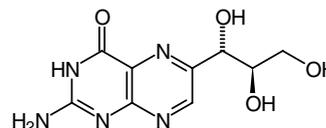

neoplasia 1 the formation of a **neoplasm** or neoplasms. 2 the formation of new tissue.

neoplasm any new and morbid formation of tissue; a tumour.

neoplastic of, or relating to, neoplasia or to a neoplasm.

neoprene poly(2-chloro-1,3-butadiene); a synthetic rubber that is resistant to oils and organic solvents and is useful for the manufacture of flexible tubing, washers, etc. for laboratory and many other uses.

neopterin the *D*-erythro enantiomer of **biopterin**; its biosynthetic precursor.

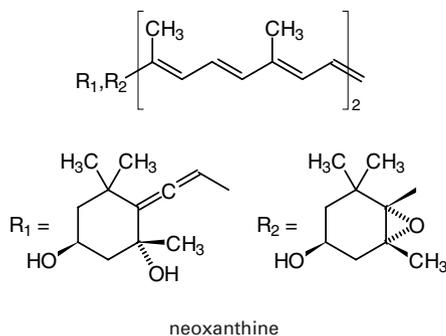

neosamine C 2,6-diamino-2,6-dideoxy-D-glucose; a constituent of **neomycin C** and some other antibiotics including **kanamycin**.

neosome the suggested secondary particulate biogenic precursor of the ribosome, intermediate between the **eosome** and the completed ribosome. Neosomes in *Escherichia coli* are particles with sedimentation coefficients of 43S and 30S.

neotenin *an alternative name for* **juvenile hormone**.

neoxanthin a carotenoid **xanthophyll** present in the leaves of all higher plants.

nephelometry a technique in which the light dispersed by a suspension is measured orthogonally to the direction of the incident light; the amount of scattered light is dependent on the number and size of the particles in the light path. *Compare turbidimetry.* —**nephelometric** *adj.*; **nephelometrically** *adv.*

nephr+ a variant form of **nephr+** (before a vowel).

nephrectomy the surgical removal of one or both kidneys. —**nephrectomize** *vb.*

nephr+ or (before a vowel) **nephr+** *comb. form* denoting kidney or kidneys.

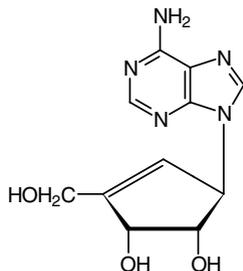

nephrocalcin or **osteocalcin-related protein precursor** a calcium-binding protein found in bone. It is expressed only in kidney; in humans and other mammals, it is also found as a urinary acidic glycoprotein that strongly inhibits formation of calcium oxalate crystals in renal tubules. It contains γ -carboxyglutamic acid residues; a modified protein lacking these is found in patients with calcium oxalate renal calculi.

nephrogenic diabetes insipidus a rare X-linked recessive genetic disorder involving renal insensitivity to vasopressin resulting in polyuria and polydipsia; it can also be acquired as a result of toxic damage to the tubules. The genetic form is associated with mutations in the V_2 receptor (see **vasopressin receptor**), two examples being substitution of Asp for Ala at position 132 and a frameshift mutation at position 246 leading to a premature stop codon and a truncated receptor.

nephron any of the structural and functional urine-secreting units that occur in the kidney. Typically each nephron is made up of a glomerulus, a proximal convoluted tubule, a loop of Henle, and a distal convoluted tubule.

nephropontin *see osteopontin.*

neplanocin A a cyclopentenyl analogue of adenosine; a natural antibiotic that inhibits *S*-adenosylhomocysteine hydrolase and vaccinia virus multiplication.

neprilysin EC 3.4.24.11; *other names*: neutral endopeptidase; endopeptidase 24.11; enkephalinase; a member of the zinc metalloendopeptidase family. It is an integral plasma membrane enzyme and is involved in the metabolism of a number of regulatory peptides including enkephalins, tachykinins, and natriuretic and chemotactic peptides.

Ner *symbol* for the nervonyl (i.e. (*Z*)-tetracos-15-enoyl) group.

NER *abbr.* for nucleotide excision repair.

Nernst distribution law when, at a constant temperature, a solute distributes itself between two immiscible phases, then the ratio of its concentrations in the two phases is constant, and is described by the relation $C_1/C_2 = K$, where C_1 and C_2 are, respectively, the amount-of-substance concentrations of the solute in phases 1 and 2 at equilibrium, and K is the distribution constant. The law only applies in dilute solution. [After Walther Hermann Nernst (1864–1941), German physical chemist.]

Nernst equation a the potential, E , of an electrode reversible to one ion in a solution containing that ion is given by:

$$E = E^\ominus + (RT/zF)\ln a,$$

where E^\ominus is the standard potential of the electrode (relative to the standard hydrogen electrode), a is the activity of the ion to which the electrode is reversible, z is the charge number of the ion, R is the (molar) gas constant, F is the Faraday constant, and T is the thermodynamic temperature. This equation can be extended to the e.m.f. of an electrolytic cell. **b** For a redox reaction, the potential of an electrode (usually platinum or gold) immersed in a redox solution, E_h , is given by:

$$E_h = E^\ominus + (RT/nF)\ln(a_{ox}/a_{red}),$$

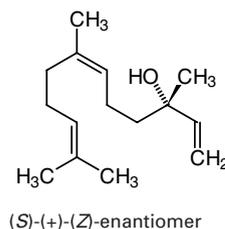

where E^\ominus is the standard redox potential of the system at a given pH (usually pH 7.0), n is the number of electrons transferred in the reaction, and a_{ox} and a_{red} are respectively the activities of the oxidized and reduced species in the solution. **c** If two solutions are separated by a membrane permeable to only one of two (or more) ions and the activities of the ions are different on either side of the membrane then a membrane potential, E_A , will be generated where

$$E_A = (RT/zF)\ln(a_L/a_R),$$

where a_L and a_R are the activities respectively of the permeable ion on the left and right sides of the membrane.

Nernst heat theorem another name for a particular formulation of the third law of thermodynamics (see **thermodynamics**).

nerolidol peruviol; 3,7,11-trimethyl-1,6,10-dodecatrien-3-ol; a widespread acyclic sesquiterpene.

nerve any of the cordlike bundles, consisting of **nerve fibres** and **glia** encased in a connective-tissue sheath, that connect the central nervous system to other parts of the body. They may be motor, sensory, or of mixed function.

nerve cell an alternative name for **neuron**.

nerve fibre the axonal process of a **neuron** together with its covering sheath. Bundles of nerve fibres running together make up a **nerve**.

nerve gas any of various poisonous gases or volatile liquids that act by inhibiting the passage of impulses through the nervous system and neuromuscular junctions. They are commonly irreversible inhibitors of **acetylcholinesterase**.

nerve growth factor 1 any of a number of polypeptides that exert a trophic effect on neurons. They play a part in the development and maintenance of sensory neurons in dorsal root ganglia and sympathetic neurons in peripheral sympathetic ganglia. **2** *abbr.*: NGF; the first known member of a family of polypeptides that act as growth factors for neurons. In addition to the general properties of such nerve growth factors, it also stimulates growth and differentiation of B lymphocytes, and stimulates histamine release from mast cells. The biologically active form of NGF contains two identical polypeptide chains of 120 amino-acid residues and known sequence and exerts its action through specific receptors in the neu-

ronal plasma membrane. It is produced by neurons, astrocytes, and Schwann cells, but also by fibroblasts, epithelial cells, activated macrophages, and smooth muscle cells. It exists as an inactive complex of two α subunits, two β subunits, and two γ subunits. The active form consists of the two β subunits, and is known as β NGF. Related proteins subsequently discovered include **brain-derived neurotrophic factor** and **neurotrophins**.

nerve growth factor receptor any of a family of plasma membrane integral proteins that bind nerve growth factors. Low-affinity and high-affinity binding is observed; high affinity binding, and action on effector systems, requires the presence of both the *trk* protooncogene product (p140^{prototrkr}) and a 75 kDa low-affinity receptor glycoprotein (p75^{NGFR}). The latter can bind **nerve growth factor** (def. 2), **brain-derived neurotrophic factor**, and **neurotrophins** 3 and 4, but it is apparent that considerable specificity exists in transduction of the signal depending on which member of the nerve growth factor family and which cell type is involved.

nerve impulse *see* **impulse** (def. 3).

nervon or **nervone** the **galactocerebroside** in which the acyl group is **nervonyl**. It was originally isolated from nervous tissue.

nervonate **1** numerical symbol: 24:1 (15); *the trivial name for* (Z)-tetracos-15-enoate, $\text{CH}_3\text{-(CH}_2\text{)}_7\text{-CH=CH-(CH}_2\text{)}_{13}\text{-COO}^-$ (*cis* isomer), the anion derived from nervonic acid, (Z)-tetracos-15-enoic acid a monounsaturated straight-chain higher fatty acid. **2** any mixture of free nervonic acid and its anion. **3** any salt or ester of nervonic acid. *See also* **nervonyl**.

nervonyl *symbol*: Ner; *the trivial name for* (Z)-tetracos-15-enoyl, $\text{CH}_3\text{-(CH}_2\text{)}_7\text{-CH=CH-(CH}_2\text{)}_{13}\text{-CO-}$ (*cis* isomer), the acyl group derived from nervonic acid, (Z)-tetracos-15-enoic acid. It occurs as the acyl moiety of the cerebroside **nervon** in brain, as a major constituent of milk phosphatidylcholines and sphingolipids in, e.g., pig and human, and in sphingolipids of other tissues.

nervous of, pertaining to, mediated by, or containing nerves; neural.

nervous system the extensive network of cells specialized to carry information, in the form of nerve impulses, to and from all parts of the body. Nervous systems occur in all orders of multicellular animals other than sponges.

nervous tissue tissue from any part of the nervous system.

nesidioblast a precursor cell of a pancreatic islet cell.

nesidioblastoma a tumour of nesidioblasts.

nesidioblastosis a pathological condition in which individual blastic pancreatic duct cells differentiate abnormally into islet cells scattered among the exocrine tissue. The condition is sometimes associated with severe infantile hyperinsulinism and hypoglycemia.

nesslerize or **Nesslerize** to treat (a sample) with **Nessler's reagent**; to test for or estimate (ammonia) by such means. *Also*: **nesslerise**, **Nesslerise**. —**nesslerization** or **nesslerisation** *n*.

Nessler's reagent an alkaline aqueous solution of potassium tetraiodomercurate(II). It gives a yellow or brown colour or precipitate when added to solutions containing ammonia or ammonium ions and is useful in the detection and quantitative estimation of microgram quantities of ammonia in aqueous solution. [After Julius Nessler (1827–1905), German agricultural chemist.]

nested deletion the systematic truncation of a DNA molecule from one end to produce a series of fragments that have an identical sequence at one end and different sequences at the other.

nested PCR primers a set of oligonucleotide primers used for the amplification of DNA by the polymerase chain reaction (PCR) in which the outermost 5' and 3' pair are used in the first phase of amplification and a second pair is designed to prime within that PCR product to produce a shorter amplified sequence. Greater specificity of amplification is expected from this use of two pairs of primers.

nestin an intermediate-filament protein whose name derives from neuroepithelial stem cells, in which it is specifically expressed. It shares significant similarity with other intermediate-filament proteins, including a set of heptad repeats.

netrin any of a family of proteins first isolated from chick brain as diffusible chemoattractants that guide commissural axons to their targets during development. Netrin 1 is expressed at high levels in the floor plate during the period when commissural axons are growing towards the floor plate, while netrin 2 is similarly expressed at

lower levels in the ventral two-thirds of the spinal chord. D netrin is a *Drosophila* homologue, expressed in midline cells of the central nervous system when commissures are forming. The proteins are related to Unc proteins (e.g., *see unc-86*) of *Caenorhabditis elegans*.

netropsin a *Streptomyces*-derived basic peptide antibiotic that selectively binds to A–T base pairs in the small groove of right-handed B conformations of DNA. It induces A to B conformational changes in DNA.

Netscape a popular **browser** available for a variety of computers and operating systems.

net sensitivity *see* **flux control coefficient**.

net synthesis increase in the total mass (of a reaction product), as opposed to any apparent increase estimated by incorporation of labelled precursor (which may arise from exchange).

neu an oncogene first described in association with a neuroblastoma after treatment of rats with ethylnitrosourea. The *neu* protooncogene (also known as *c-erbB2*, *NGL*, and *HER2*) encodes a 185 kDa transmembrane glycoprotein with tyrosine kinase activity, related to but distinct from the **epidermal growth factor receptor** (EGFR). The *neu* gene product, Neu, possesses a cysteine-rich extracellular domain, a transmembrane domain, and an intracellular tyrosine kinase domain. EGF does not bind to Neu, but a factor known as **Neu-activating factor** (NAF) binds specifically to Neu and will bind to EGFR. Neu was originally identified in brain, and may play a critical role in neurogenesis. The rat *neu* oncogene is activated constitutively by a point mutation in the transmembrane domain. The association of *neu* with human cancer through gene amplification, or overexpression of the protein product, has been supported by work with breast and ovarian cancer.

Neu 1 *symbol for* a residue (or sometimes a molecule) of **neuraminic acid**. **2** the product of the *neu* gene.

NeuAc or (*formerly*) **AcNeu** *symbol for* a residue (or sometimes a molecule) of any isomer of acetylneuraminic acid, i.e. **sialic acid**. *See also* **NeuNAc**, **NeuOAc**, **neuraminic acid**.

Neu-activating factor *see* **neu**.

Neuberg ester *an old name for* D-fructose 6-phosphate. *See* **fructose 6-phosphate**.

Neuberg's first form of fermentation the normal anaerobic alcoholic fermentation of carbohydrate by yeast to yield two moles each of ethanol and carbon dioxide per mole of glucose fermented. [After Carl Alexander Neuberg (1877–1956); German biochemist.]

Neuberg's second form of fermentation the anaerobic fermentation of carbohydrate by yeast in the presence of sodium hydrogen sulfite. The acetaldehyde formed normally, which would act as a hydrogen acceptor for the reoxidation of NADH, is trapped as its bisulfite addition product, and its place is taken by dihydroxyacetone phosphate (i.e. glycerone phosphate), which is reduced to *sn*-glycerol 3-phosphate; this is then dephosphorylated to glycerol. Thus one mole each of glycerol, acetaldehyde–bisulfite complex, and carbon dioxide is formed per mole of glucose fermented.

Neuberg's third form of fermentation the anaerobic fermentation of carbohydrate by yeast in alkaline conditions. The acetaldehyde formed normally, which would act as a hydrogen acceptor for the reoxidation of NADH, undergoes a **Cannizzaro reaction** to form acetic acid and ethanol, and its place is taken by dihydroxyacetone phosphate (e.g. glycerone phosphate), which is reduced to *sn*-glycerol 3-phosphate; this is then dephosphorylated to glycerol. Thus one mole each of glycerol and carbon dioxide, and one half mole each of ethanol and acetic acid, are formed per mole of glucose fermented.

NeuGc *symbol for* a residue (or sometimes a molecule) of *N*-glycolylneuraminic acid. *See also* **sialic acid**.

NeuNAc or **Neu5Ac** *symbol for* a residue (or molecule) of *N*-acetylneuraminic acid (i.e. **sialic acid**). It accumulates in lysosomes in Salla disease and infantile sialic acid storage disease, and in cell cytosol in sialuria.

NeuOAc *symbol for* a residue (or molecule) of *O*-acetylneuraminic acid. *See* **sialic acid**.

neur+ *a variant form of neuro+* (*before a vowel*).

neural of, or pertaining to, a nerve or nerves, or to the nervous system.

neural cell adhesion molecule *abbr.*: NCAM; any type I mem-

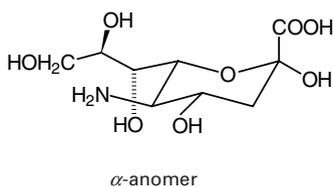

brane glycoprotein of the immunoglobulin superfamily that is involved in neuron–neuron adhesion, neurite fasciculation, outgrowth of neurites, etc. NCAMs have poly- α 2,8-sialic acid as a post-translational modification. The human protein NCAM-L1 shows strong homology with a *Drosophila* protein, **neuroglian**.

neural crest a group of embryonic cells, derived from the roof of the neural tube, that migrate to different locations and give rise to various types of adult cells.

neural network or **artificial neural network** a general class of machine-learning algorithms, inspired by the neural structure of the brain, in which multiple simple processing units are connected by adaptive weights.

neuraminic acid **1** the anion derived from **neuraminic acid**. **2** any salt or ester of neuraminic acid.

neuraminic acid *symbol:* Neu; the monosaccharide 5-amino-3,5-dideoxy-D-glycero-D-galacto-nonulosonic acid; it may be regarded as the aldol-condensation product of pyruvic acid and N-acetyl-D-mannosamine. It is not found free in nature, but is the parent structure of a family of aminodeoxy sugars containing nine or more carbon atoms that occur widely, especially in glycoproteins and gangliosides; they include the **sialic acids**.

neuraminidase a former name for **sialidase**.

neuraminosyl a trivial name for the glycosyl group derived from **neuraminic acid** by removal of the hydroxyl group from the anomeric carbon atom of the cyclic structure.

neuraminoyl a trivial name for the acyl group derived from **neuraminic acid** by removal of the hydroxyl group from the carboxyl group.

neuregulin any member of a family of closely related proteins implicated as regulators of neural and muscle development, and differentiation and oncogenic transformation of mammalian epithelia. They include the Neu differentiation factor (*see neu*) and the **heregulins**. They exert their effects through binding to, and activating, receptors of the ErbB2/Neu receptor family. Neuregulins stimulate proliferation of Schwann cells, increase the rate of synthesis of acetylcholine receptors in cultured muscle cells, and are concentrated at nerve–muscle synapses.

neurexin any of a family of cell-surface receptors expressed from three genes in the brain and concentrated in neurons. They are implicated in axon guidance and synaptogenesis. Some are probably signalling molecules. They are highly polymorphic from alternative splicing, and include secreted variants. They contain single transmembrane regions and extracellular domains with repeat sequences similar to those in the globular C-terminal region of laminin A (*see laminin*) and **agrin**. Each gene contains two independent promoters so that transcription produces two classes of mRNA, which encode proteins with different N termini, the larger being referred to as α -neurexins and the shorter as β -neurexins. The former contain three epidermal growth factor domains, an O-linked sugar domain, a transmembrane domain, and a short cytoplasmic tail. The α - and β -neurexins differ in their N-terminal sequences but have identical C termini, including the sugar-rich, transmembrane, and cytoplasmic domains. The crystal structure of the laminin A-like sequence (\approx 200 residues) of neurexin I is similar to that of the pentraxins and some lectins, being a beta sandwich consisting of 14 beta strands.

neurilemma or **neurolemma** the thin outer sheath of cells surrounding the axon (and myelin sheath) of larger peripheral nerves or surrounding the axoplasm of unmyelinated nerves.

neurite a general term for a dendrite or an axon.

neuritic plaque an extracellular mass of β -amyloid filaments that is

associated with dystrophic axons and dendrites, microglia, and astrocytes. In **Alzheimer's disease** such plaques occur in areas of the brain that serve cognition and memory.

neuro+ or (*before a vowel*) **neur+** *comb. form* denoting a nerve or the nervous system.

neuroactive (of an agonist or antagonist) having an effect on the nervous system.

neurocalcin an EF-hand Ca^{2+} -binding protein found in retina and brain neurons, involved in the calcium-dependent regulation of rhodopsin phosphorylation.

neurocan a chondroitin sulfate proteoglycan of brain (rat protein: 1235 amino acids). It is developmentally regulated with regard to mass, concentration, carbohydrate composition, sulfation, and localization.

neurochemistry the study of the chemical composition of, and the chemical reactions occurring in, nervous tissue. —**neurochemical** *adj.*

neurocrine **1** describing or relating to a neuron that secretes an agonist into a synapse with another neuron; describing or relating to such an agonist. **2** such an agonist, e.g. a **neurotransmitter**.

NeuroD1 *abbr. for* neurogenic differentiation factor 1; *other name:* BETA 2; a transcription factor, required for normal development of pancreatic islets, that regulates the insulin gene. Mutations are associated with type 6 maturity-onset diabetes of the young.

neuroendocrine **1** describing or relating to a neuron that secretes an agonist into the bloodstream; describing or relating to such an agonist. **2** such an agonist; a **neurohormone**.

neuroendocrine convertase EC 3.4.21.93; *abbr.:* NEC; *other name* prohormone convertase. Any of the enzymes that act at paired dibasic amino acids in precursors of hormones and other **polyproteins**, to cleave the precursor into individual mature proteins. The catalytic activity depends on the Asp-His-Ser **charge-relay system**. Substrates for NEC1 include **proopiomelanocortin**, **renin**, **enkephalin**, **dynorphin**, **somatostatin**, and **insulin**. NEC2 and NEC3 have also been described.

neuroendocrinology the study of the interrelations between the nervous system and the endocrine system. —**neuroendocrinological** *adj.*

neurofascin a chick neurite-associated glycoprotein implicated in axon extension; it is an axonal surface recognition molecule of the immunoglobulin superfamily. At the N terminus, it has six immunoglobulin-like motifs, followed by four fibronectin type III motifs, a proline-alanine-threonine-rich region, a transmembrane domain, and a 113-residue cytoplasmic domain.

neurofibril any of the very fine fibres, visible by light microscopy, that occur in the cell bodies, axons, and dendrites of neurons.

neurofibrillary tangle an intraneuronal inclusion composed of bundles of paired helical filaments consisting mainly of **tau protein**. Neurofibrillary tangles are present in the cerebral cortex of virtually all patients with Alzheimer's disease.

neurofibromatosis any of a number of disorders associated with the presence of multiple **neurofibromas**, benign tumours consisting of a mixture of Schwann cells and fibroblasts. Type 1 is a common autosomal dominant disorder that results from mutations in **neurofibromin**. Type 2 is also autosomal dominant but rare and results from mutations in merlin (also called schwannomin).

neurofibromin *other name:* neurofibromatosis-related protein (NF-1); a GTPase activating protein (*see GAP* (def. 2)), the product of the *Nf1* tumour-suppressor gene, that stimulates the GAPase activity of the **RAS** oncogene product, thus inactivating it. It appears to be implicated in the pathogenesis of **neurofibromatosis**.

neurofilament a type of **intermediate filament** found in neurons.

neurogenin a transcription factor that promotes neuronal differentiation by inducing neuron-specific genes and by repressing glial cell-specific genes.

neuroglia an alternative name for **glia**.

neuroglian a probable cell-adhesion molecule, with structural similarities to **neural cell-adhesion molecule L1**. It is found in neurons and glia of the developing nervous system. It has a single transmembrane domain, with extracellular immunoglobulin-like and fibronectin-type domains.

neuroglobin an oxygen-binding protein of vertebrate brain that

may be neuroprotective against ischemia. In mouse retina (which has a very high oxygen demand) its concentration is a hundred times higher than in the brain.

neurohormone any organic compound produced by neurons and released into the circulation to act as a chemical messenger; the term is sometimes extended to all **neurotransmitters** whether released or not. —**neurohormonal** *adj.*

neurohumour or (*US*) **neurohumor** a neurohormone or a neurotransmitter. —**neurohumoral** *adj.*

neurohypophysis (*pl.* **neurohypophyses**) the posterior lobe of the pituitary gland, *also called neural lobe or pars nervosa*. It secretes the peptide hormones oxytocin and vasopressin, and also possibly some others. *Compare adenohypophysis*. —**neurohypophysial** or **neurohypophysial** *adj.*

neuroinformatics *see informatics*.

neurokinin A or **neuromedin L** or **substance K** the peptide hormone

His-Lys-Thr-Asp-Ser-Phe-Val-Gly-Leu-Met

derived from **protachykinin β precursor**. It is a member of the **tachykinin** family and is a potent bronchoconstrictor. The related peptide [β Ala⁸]neurokinin A 4–10,

H-Asp-Ser-Phe-Val- β Ala-Leu-Met-NH₂,

is a potent and selective **substance K receptor** agonist.

neurokinin B or **neuromedin K** a member of the **tachykinin** family that has neuroendocrine and neuroexcitatory functions, especially in the olfactory, gustatory, and visceral systems. It is a potent bronchoconstrictor. It has the sequence

Asp-Met-His-Asp-Phe-Phe-Val-Gly-Leu-Met-NH₂

Neurokinin B acts through a G-protein-coupled receptor, known as NK-3, linked to the phosphatidylinositol cycle.

neurolemma a variant spelling of **neurilemma**.

neuroleptic any drug used to treat major psychosis, e.g. schizophrenia or mania. Such drugs include phenothiazines, e.g. **chlorpromazine**, and butyrophenones, e.g. **haloperidol**.

neuroleukin a protein produced by activated T lymphocytes that induces immunoglobulin secretion and is a neurotrophic factor. It is identical with monomeric **glucose-6-phosphate isomerase**.

neurolysin EC 3.4.24.16; *other name*: neurotensin endopeptidase; an enzyme that catalyses the preferential cleavage in neurotensin of Pro¹⁰-|-Tyr¹¹.

neuromedin B a decapeptide first isolated from porcine spinal cord. Its structure,

Gly-Asn-Leu-Trp-Ala-Thr-Gly-His-Phe-Met,

has close sequence homology to **bombesin**, with which it shares mitogenic and growth-promoting properties. In rat brain its concentration is highest in the olfactory bulb, but is also high in the hypothalamus, hippocampus, and spinal cord. The B in its name indicates its similarity to bombesin.

neuromedin C a neuropeptide similar in its structure,

Gly-Asn-His-Trp-Ala-Val-Gly-His-Leu-Met,

and in its actions to **neuromedin B** and **bombesin**.

neuromedin L an alternative name for **neurokinin A**.

neuromedin N a hexapeptide whose C-terminal tetrapeptide is identical to that of **neurotensin**.

neuromodulator any endogenous agent that influences the function of a **neurotransmitter** but has no direct excitatory or inhibitory postsynaptic actions. The term usually implies long-latency and long-lasting effects (i.e. seconds to days).

neuromuscular of, pertaining to, or affecting both nervous and muscular tissue.

neuromuscular junction the place of contact between the motor end-plate of the fibre of a motor neuron and the membrane of a muscle fibre supplied by the neuron. Impulses are transmitted across the gap by diffusion of a neurotransmitter. *Compare synapse*.

neuron or **neurone** or **nerve cell** a cell that is specialized for the transmission of nerve impulses. Neurons are the structural and functional units of the nervous system. Each consists of an enlarged portion, the cell body or perikaryon, containing the nucleus and from which project a variable number of threadlike processes. Of these

the short branched dendrites convey impulses towards the cell body, while a longer single nerve fibre, or axon, conveys impulses away from the cell body. The axon is unbranched except at the nerve ending. —**neuronal** *adj.*

neuronal PAS domain protein 2 *see NPAS2*.

neuronatin a protein that is highly expressed in neonate mammalian brain, and may be involved in terminal brain differentiation.

neuropeptide (*sometimes*) any peptide with neuroendocrine activity.

neuropeptide K a polypeptide hormone, DADSSIEKQVALLKALYGHGQISHKRHKTDSEFVGLM-NH₂, derived from **protachykinin β precursor**. It exhibits a wide spectrum of activities overlapping those of other members of the **tachykinin** family, with which it shares the C-terminal sequence FXLM-NH₂.

neuropeptide Y or (*formerly*) **melanostatin** *abbr.*: NPY; a 36-residue peptide neurotransmitter, structure YPSKPDNPGEDA-PAEDMARRYSSALRHHYINLITRQRY-amide (human, porcine has Leu¹⁷), found in the autonomic nervous system and in relatively high concentrations in adrenal glands, brain, and heart. It is a potent stimulator of feeding; leptin inhibits NPY gene expression and release. NPY also regulates secretion of **gonadotropin releasing hormone**. It shows considerable sequence homology with **peptide YY** and **pancreatic polypeptide**. [Leu³¹, Pro³⁴]NPY is a selective agonist for a Y₁ receptor subclass. *See also neuropeptide-Y receptor*.

neuropeptide-Y receptor *abbr.*: NPY receptor or Y receptor; a G-protein-associated membrane receptor that binds **neuropeptide Y** (NPY) and inhibits adenylate cyclase and Ca²⁺ channels. Four types have been recognized. A fifth type, Y5, is suggested to mediate the effects of NPY on feeding.

neurophysin any cystine-rich, single-chain polypeptide present in the neurohypophysis. Neurophysin I binds **oxytocin**, with which it shares a common precursor. For example, in rat the precursor protein consists of 125 amino acids, of which residues 1–19 are the signal peptide, 20–28 are oxytocin, and 32–125 are neurophysin I. Neurophysin II binds **vasopressin**, and again shares a common precursor. *See also vasopressin-neurophysin 2-copeptin precursor*.

neurophysin II *another name for MSEL-neurophysin*.

neuropilin *abbr.*: NP; an integral membrane protein that, like **plexin**, is a coreceptor for some semaphorins.

neuroscience any of the sciences dealing with the nervous system; such sciences collectively.

neurosecretion 1 the process of secretion of a substance by a (specialized) nerve cell. **2** a product of such a secretion; a **neurocrine** (def. 2) or **neuroendocrine** (def. 2). —**neurosecretory** *adj.*

neuroserpin a **serpin** that is closely homologous to α_1 -antitrypsin and is secreted by neurons, particularly during their growth phase.

neurosoma (*sometimes*) a mitochondrion of a nerve cell.

Neurospora a genus of ascomycete microfungi. The species *N. crassa* has been widely used in biochemical and genetic studies. It is commonly found as a mould on bread that has been kept for too long.

neurotensin a tridecapeptide, Glp-Leu-Tyr-Glu-Asn-Lys-Pro-Arg-Arg-Pro-Tyr-Ile-Leu-OH, found in mammalian brain and gut, especially in **N cells**, packaged within secretory vesicles. It is released from the hypothalamus into the circulation. Although initially shown to induce hypotension, it is now known to have a wide variety of pharmacological actions, including muscle contraction. The precursor gives rise to neurotensin and two other derivatives, neuromedin and neuromedin N.

neurotensin endopeptidase *see neurolysin*.

neurotoxin any toxin that acts specifically or primarily on nervous tissue. —**neurotoxic** *adj.*

neurotransmission the transmission of nerve impulses from a neuron to another excitable cell via a neurotransmitter.

neurotransmitter any chemical substance released at the distal end of the axon of a neuron in response to the arrival of a nerve impulse that, by diffusing across a **synapse** or other junction, is capable of transmitting the impulse to another neuron, to a muscle cell, or to another excitable cell or, in the case of inhibitory neurotransmitters, of inhibiting the transmission. The neurotransmitter is stored in synaptic vesicles in the axon terminal; it is released into the synaptic cleft on arrival of the action potential and diffuses to and

stimulates receptors in the membrane of the post-synaptic cell. An essential component of the mechanism is a means to inactivate the neurotransmitter, e.g. by acetylcholinesterase action on acetylcholine. Both excitatory (see **cholinoceptor**, **purinoceptor**, and **glutamate receptor**) and inhibitory (see **GABA receptor** and **glycine receptor**) neurotransmitters are known.

neurotrophic factor *see* **brain-derived neurotrophic factor**.

neurotrophin *abbr.*: NT; any of a group of growth factors, similar to **nerve growth factor** but with different tissue specificities. The first to be discovered was named neurotrophin 3, as two proteins with neurotrophic properties had already been discovered (nerve growth factor and **brain-derived neurotrophic factor**). Neurotrophins have properties similar to these latter. Neurotrophins 3 to 6 have been described.

neurotrophic having a particular affinity for, or affecting nervous tissue.

neurotrypsin a serine protease (875 amino acids) present in presynaptic nerve endings and expressed mainly in cerebral cortex and motor nuclei of the brainstem. It appears at 7–15 weeks of human fetal life. A truncating mutation is associated with a nonsyndromic form of mental retardation.

neurturin a secreted protein that is structurally related to glial cell-derived neurotrophic factor and persephin, and, like them, binds a specific GPI-anchored membrane protein that recruits and signals through RET.

neutral 1 being neither acidic nor basic (or alkaline). **2** having no net charge or electric potential.

neutral amino acid any amino acid containing equal numbers of potentially anionic and cationic groups, as distinct from acidic and basic amino acids.

neutral density filter *an alternative term for neutral filter*.

neutral fat *see* **neutral lipid**.

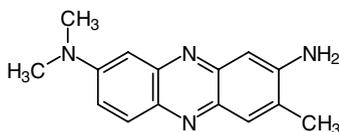

neutral filter or **neutral density filter** (*in photography and photometry*) a filter that attenuates all frequencies of light uniformly so that the relative spectral energy distribution of the transmitted light is the same as that of the incident light.

neutrality the condition, quality, or state of being **neutral** (def. 1, 2) or intermediate.

neutralize or **neutralise** to render **neutral** (def. 1, 2) or ineffective; to counteract. —**neutralization** or **neutralisation** *n*.

neutral lipid *an operational term for* any lipid that is soluble only in solvents of very low polarity. Neutral lipids are divided into two main groups: (1) acylglycerols (glycerides), i.e. fatty-acid esters of glycerol; and (2) waxes, i.e. fatty-acid esters of long-chain monohydroxy alcohols.

Neutral Red an indicator dye that changes colour from red to orange-brown over the pH range 6.8–8.0.

neutral solution any aqueous solution in which the activities of the hydrogen and hydroxide ions are equal. Such a solution in which water is the sole solvent has a pH of 7.00 at 25° C.

neutron *symbol*: *n*; an elementary particle of zero charge; nucleon number 1; rest mass 1.6749×10^{-27} kg (1.0086 Da); spin 1/2. Neutrons are present in the nuclei of all atoms (except the hydrogen atom), where they are stable; when free, a neutron has a mean life of 932 s, decaying to a proton and an electron.

neutron activation analysis *an alternative name for radioactivation analysis*.

neutron diffraction a technique that is similar in principle to **X-ray diffraction** by a crystal, and is applicable particularly to biopolymers and particulate structures. Because hydrogen atoms make a much more substantial contribution to the scattering of neutrons than to X-ray scattering the technique is useful for refining partially deter-

mined structures obtained by the use of X-rays. In rare cases it has been used for determination of absolute configuration.

neutron flux (density) the number of free neutrons passing through unit volume multiplied by their mean velocity.

neutron number *symbol*: *N*; a dimensionless physical quantity, having an integral value for any given nuclide, equal to the number of neutrons contained in the nucleus of an atom of the nuclide. Hence, it is equal to the arithmetical difference between the **nucleon number**, *A*, of the nuclide and the **proton number**, *Z*, of the relevant chemical element; i.e. $N = A - Z$.

neutron scattering *see* **small-angle scattering**.

neutrophil or **neutrophil leukocyte** or **neutrophilic leukocyte** the most numerous **polymorphonuclear leukocyte** found in the blood; a phagocytic cell of the myeloid series that is distinguished by the presence of cytoplasmic azurophil granules and other granules that take up neither acidic nor basic dyes. It plays a major role in the inflammatory response, undergoing chemotaxis towards sites of infection or wounding.

Newman projection a two-dimensional representation of a molecule in which the atoms are arranged as they would be seen if the molecule were viewed from one end along the carbon–carbon bond nearest to the observer. *See also* **conformation**.

newton *symbol*: *N*; the SI derived unit of force, defined as the force required to give a mass of one kilogram an acceleration of one metre per second per second; i.e. $1 \text{ N} = 1 \text{ kg m s}^{-2} = 1 \text{ J m}^{-1}$ ($= 10^5$ dynes).

Newtonian flow the type of flow displayed by a **Newtonian fluid**.

Newtonian fluid any fluid whose (coefficient of) viscosity is independent of flow rate, conforming to **Newton's law of viscosity**. [After (Sir) Isaac Newton (1642–1727), English astronomer, mathematician, philosopher, and physicist.]

Newton's law of viscosity a law, derived by Isaac Newton, that describes the flow of almost all fluids of low relative molecular mass and also that of some solutions of macromolecules. A fluid moving between two parallel plates, in the *x* direction with a velocity *v*, is thought of as a number of infinitesimal layers, each of which slides along the adjacent one, the frictional resistance between adjacent layers generating an orthogonal velocity gradient, in the *y* direction. The frictional force, *f*, between the fluid layers is then proportional to the area, *A*, of the layers and to the velocity gradient between them, such that:

$$f = \eta A (dv/dy),$$

where the constant η is known as the **coefficient of viscosity** (or **viscosity** for short) at the temperature of measurement; its reciprocal, $1/\eta$, is the **fluidity**.

new yellow enzyme *an obsolete name for* the enzyme D-amino-acid oxidase (EC 1.4.3.3), a yellow flavoprotein (FAD) with wide specificity for D-amino acids and acting also on glycine. It was so named to distinguish it from **old yellow enzyme**. *See* **amino-acid oxidase**.

New Zealand obese mouse *abbr.*: NZO mouse; one of a number of strains of genetically obese mice that are used in metabolic and endocrine research. The obesity is moderate in character and there is an associated hyperinsulinemia and hyperglycemia.

nexin a protein found in the **axoneme** of eukaryotic cilia and flagella. It forms interconnections between the microtubule outer doublets that surround the inner central pair of microtubules. *See also* **glial-derived nexin**.

nexin 1 *other names*: protease nexin I (*abbr.*: PN-I); a glycoprotein that promotes neurite extension, and is an extracellular **serpin**-like serine protease inhibitor.

nexin 2 the secreted isoform of the Alzheimer's amyloid β -protein precursor (*see* **β -amyloid peptide**). *See also* **Alzheimer's disease**.

nexus (*in cytology*) *an alternative name for* **gap junction**.

NF-1 *see* **CTF**, **neurofibromin**.

NF2 *abbr. for* neurofibromatosis type-2 tumour suppressor; *see* **merlin**.

NF-AT *abbr. for* nuclear factor of activated T cells; a transcription factor complex that activates promoters of the genes for interleukins 2 and 4. It consists of cytoplasmic and nuclear components. The cytoplasmic component, made up of four subunits (NF-ATc1

to NF-ATc4), binds to and is dephosphorylated by calcineurin, then enters the nucleus where it meets the nuclear component (NF-ATn, or NF-AT interacting protein).

NF- κ B a transcription factor for eukaryotic RNA polymerase II promoters. In humans the active protein is a heterodimer of two DNA-binding subunits (p50) which belong to the same family as the **dorsal protein**. It is found in cytoplasm as an inactive complex with an inhibitory subunit, I κ B; activation of NF- κ B involves its release from its inhibitory subunit. A 105 kDa protein is the precursor of the p50 subunits. These bind to the **kappa-B** consensus sequence, GGRN-NYYCC, e.g. GGGGACTTCC in mouse and human.

NF-E1 see GATA-1.

ng symbol for nanogram.

NGF abbr. for nerve growth factor.

L-NHA abbr. for N^G-hydroxy-L-arginine.

NheI a type 2 restriction endonuclease; recognition sequence: G \uparrow CTAGC.

NHS abbr. for N-hydroxysuccinimide.

Ni symbol for nickel.

niacin an alternative name for **nicotinic acid**.

niacinamide an alternative name for **nicotinamide**.

NIAP abbr. for neuronal inhibitor of apoptosis protein. See IAP.

niibrin a protein that is missing in cell lysates from persons suffering from **Nijmegen breakage syndrome**. It is phosphorylated by ATM, a protein kinase whose deficiency due to mutation is the cause of **ataxia telangiectasia**.

nicastrin a type 1 transmembrane glycoprotein (709 amino acids) that associates with presenilins 1 and 2 and modulates the release of β -amyloid peptide from β -amyloid precursor protein.

NICE element abbr. for nodule infected cell expression element, a name given to an AT-rich element in *Sesbania rostrata* leghemoglobin glb3.

NICER elements a name suggested for a family of genes that are nerve growth factor-inducible, cyclic AMP-extinguishable, and retrovirus-like, hence the acronym.

nick 1 an interruption in the covalent continuity of one strand of a double-stranded nucleic-acid molecule. **2** to produce a nick in a nucleic-acid molecule. See also **nick translation**.

nickase an endodeoxyribonuclease present in phage-infected *Escherichia coli* cells that gives rise to single-strand breaks (nicks) in duplex DNA.

nickel symbol: Ni; it is a ferromagnetic, metallic transition element of group 10 of the IUPAC **periodic table**; atomic number 28; relative atomic mass 58.69. It consists of a mixture of five stable nuclides of which the two most abundant are those of mass numbers 58 and 60; its commonest valence is ii. Nickel's abundance in the earth's crust is 0.018% and it is an essential trace element for living organisms. Several artificial radionuclides of nickel are known, including nickel-56 (γ -emitter; half-life 6.1 days) and nickel-63 (emits β^- radiation, 0.066 MeV; half-life 100 years).

nickel-iron hydrogenase any of a family of hydrogenases (EC 1.12..) present in some bacteria, which have an active site comprising a nickel and an iron atom, the iron being bound by two cyanide and one carbonyl ligands. They also contain other iron-sulfur clusters, and in some cases flavin.

nicking-closing enzyme or **nicking-and-closing enzyme** see type I DNA topoisomerase.

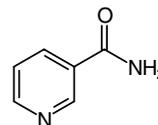

nick translation a procedure for preparing radioactively labelled DNA, especially for use as probes in hybridization experiments. Single-stranded nicks are introduced into unlabelled DNA, usually by limited treatment with deoxyribonuclease I, exposing 3'-hydroxyl termini. *Escherichia coli* DNA polymerase I (at low temperature, $\approx 15^\circ\text{C}$) is then used successively to incorporate radioactive nucleotides (present as dNTPs in the reaction mixture) to form a new, radioactively labelled polynucleotide strand while the 5'→3' exonuclease activity of the polymerase concomitantly hydrolyses the 5' termini ahead of the growing strand, liberating 5'-mononucleotides. The reaction thus progressively replaces nucleotide residues by their labelled counterparts in a DNA duplex, which is otherwise unchanged except for the translation of the nick, i.e. its progressive displacement towards the 3' end of the strand. (The

word 'translation' in the name may be misleading as the function involved is replication.)

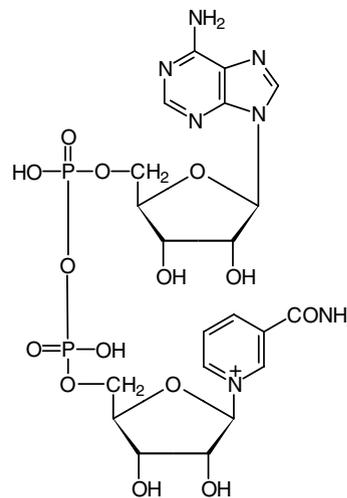

Nicol prism an optical device constructed of two prisms of calcite cemented together with Canada balsam, used for producing plane polarized light and/or determining its orientation. It has now largely been superseded by Polaroid filters, etc. [After William Nicol (1768–1851), British physicist.]

nicotianamine the metabolic precursor of the phytosiderophores avenic acid (of oats) and mugineic acid (of barley). It is derived from the α -aminobutyrate moiety of *S*-adenosylmethionine.

nicotinamide the recommended trivial name for pyridine-3-carboxamide, the amide of **nicotinic acid**; also called **niacinamide**. It is a member of the B complex of vitamins, and is nutritionally equivalent to nicotinic acid. It occurs widely in living organisms, usually in combined form.

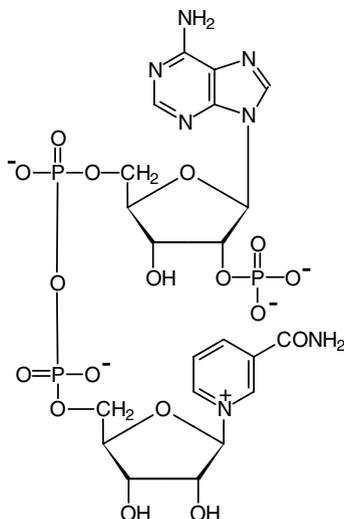

nicotinamide-adenine dinucleotide abbr.: NAD⁺ or NAD; if the oxidation state is not to be specified; nicotinamide(1)- β -D-ribose(5')diphospho(5')adenosine; an atypical dinucleotide containing a phosphoric anhydride linkage in place of the usual phosphodiester linkage between the component mononucleotide units, i.e. between nicotinamide mononucleotide and adenylic acid. It is the specific coenzyme in numerous oxidoreductase enzyme reactions, although in a number it functions interchangeably with **nicotinamide-adenine dinucleotide phosphate**. In these reactions it stereospecifically accepts a hydrogen atom at position 4 of the pyridine ring, plus an electron, to form **nicotinamide-adenine dinucleotide (reduced)**. It acts also as a donor in the ADP-ribosylation of some eukaryotic and prokaryotic proteins. The α anomer is inactive as a coenzyme. *Former names*: codehydrogenase I; coenzyme I (Co I); cozymase; diphosphopyridine nucleotide (DPN). See also **nicotinamide-adenine dinucleotide (reduced)**.

nicotinamide-adeninedinucleotidephosphate abbr.: NADP⁺; nicotinamide(1)- β -D-ribose(5')diphospho(5')adenosine 2'-phosphate; a coenzyme with a structure and coenzymic mechanism related to those of **nicotinamide-adenine dinucleotide**, although it functions as the sole coenzyme for fewer oxidoreductases and tends to be involved more in synthetic than in energy-yielding reactions. *Former names*: codehydrogenase II; coenzyme II (Co II); phospho-

nicotinamide-adenine dinucleotide phosphate (reduced)

cozymase; triphosphopyridine nucleotide (TPN). *See also* **nicotinamide-adenine dinucleotide phosphate (reduced)**.

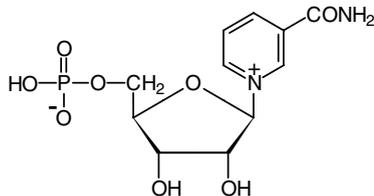

nicotinamide-adenine dinucleotide phosphate (reduced)

abbr.: NADPH; 3-aminocarbonyl-1,4-dihydropyridine(1)- β -D-ribose(5')diphospho(5')adenosine 2'-phosphate; the reduced form of the coenzyme **nicotinamide-adenine dinucleotide phosphate**. As in **nicotinamide-adenine dinucleotide (reduced)** the carbon atom at position 4 of the 1,4-dihydropyridine ring is prochiral. *See also* **NAD(P)⁺ stereospecificity**. *Former names*: reduced codehydrogenase II; reduced coenzyme II (Co IIH₂); reduced phosphocozymase; reduced triphosphopyridine nucleotide (TPNH).

nicotinamide-adenine dinucleotide (reduced)

abbr.: NADH; 3-aminocarbonyl-1,4-dihydropyridine(1)- β -D-ribose(5')diphospho(5')adenosine; the reduced form of the coenzyme **nicotinamide-adenine dinucleotide**. The carbon atom at position 4 of the dihydropyridine ring is prochiral; removal of one of the two hydrogen atoms from position 4 (or introduction of a hydrogen atom at this position into the oxidized form) through the agency of an NAD-linked oxidoreductase is stereospecific, the two hydrogen atoms being designated *pro-R* (or H_A) or *pro-S* (or H_B), and the two corresponding aspects of the (dihydro)pyridine ring frequently being known as the *A* face and the *B* face. The α anomer is inactive as a coenzyme. *Former names*: reduced codehydrogenase I; reduced coenzyme I (Co IH₂); reduced cozymase; reduced diphosphopyridine nucleotide (DPNH). *See also* **NAD(P)⁺ stereospecificity**.

nicotinamide mononucleotide *symbol*: NMN; nicotinamide(1)- β -D-ribose 5'-phosphate; the mononucleotide produced when **nicotinamide-adenine dinucleotide** acts as a donor of an adenylyl group in the activation of DNA ligase.

nicotinamide nucleotide any nucleotide that contains combined nicotinamide, e.g. **nicotinamide-adenine dinucleotide (reduced)**, **nicotinamide-adenine dinucleotide phosphate (reduced)**.

nicotinamide-nucleotide adenylyltransferase EC 2.7.7.1; *other name*: NAD⁺ pyrophosphorylase; an enzyme that catalyses the formation of NAD⁺ from ATP and nicotinamide ribonu-

nifedipine

cleotide with release of pyrophosphate and NAD⁺. *See also* **NAD⁺ synthase**, **NAD⁺ synthase (glutamine-hydrolysing)**.

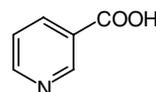

nicotinate pyridine 3-carboxylate; the anion derived from **nicotinic acid**.

nicotinate mononucleotide 3-carboxylatopyridine(1)- β -D-ribose 5'-phosphate; an intermediate in the biosynthesis of nicotinamide-adenine dinucleotide. It reacts with ATP to form deamido-NAD, which is subsequently converted to NAD by a glutamine-dependent amidation of the carboxyl group.

nicotine (S)(-)-3-(1-methyl-2-pyrrolidinyl)pyridine; the principal example of a number of related very poisonous and addictive alkaloids extractable from the dried leaves of various species of tobacco, especially *Nicotiana tabacum*. It is an agonist of the nicotinic class of **cholinoceptors**. —**nicotinic adj.**

nicotinic acetylcholine receptor *see* **cholinoceptor**.

nicotinic acid *abbr.*: NA; *the recommended trivial name for* pyridine 3-carboxylic acid, *also known as* niacin. It is a member of the B complex of vitamins, nutritionally equivalent to **nicotinamide**. At physiological pH values it exists virtually exclusively as the nicotinate anion.

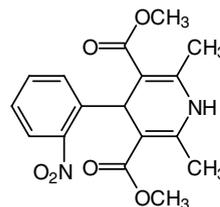

nidogen or **entactin** a sulfated glycoprotein that is widely distributed in basement membranes, and tightly associated with **laminin**.

Niemann-Pick disease *an alternative name for* **sphingomyelin lipidosi**. [After Albert Niemann (1880–1920), German physician.]

Niemann-Pick protein C a membrane protein of late endosomes and the *trans* Golgi network that when mutated causes Niemann-Pick disease types C and D (*see* **sphingomyelin lipidosi**). The gene at 18q11 encodes a protein of 1278 amino acids, which contains 13 transmembrane segments and a leucine-zipper domain. Five of the transmembrane segments have significant homology with the sterol-sensing domain of **SCAP**, HMG-CoA reductase, and Patched.

nif the symbol for any gene controlling bacterial nitrogen fixation; individual genes are distinguished by suffixed capital letters, e.g. *nifB*, *nifQ*. In *Klebsiella pneumoniae* the *nif* cluster has at least 18 genes, arranged in seven distinct operons with no other interspersed genes; the total length of the *nif* region is \approx 24 kb. The two polypeptide subunits of component I of **nitrogenase** and the polypeptide subunit of component II are each controlled by a single *nif* gene; the production and insertion of iron-molybdenum cofactor (FeMo-co) into component I appears to require three to six genes; the production of mature component II is controlled by two to four genes; two electron-transporting proteins are coded for by one gene each; and three or more genes are concerned with regulating expression of others. Six genes are required for the production and insertion of iron-molybdenum cofactor (Fe-Mo-co) into component I. Two genes, *nifS* and *nifU*, are required for the assembly of iron-sulfur clusters; *nifS* is a cysteine desulfurase, EC 2.8.1.7, which provides the sulfide, and *nifU* provides a scaffold for assembly of the clusters.

nifedipine 1,4-dihydro-2,6-dimethyl-4-(2-nitrophenyl)-3,5-pyridinedicarboxylic acid dimethyl ester; one of the dihydropyridine calcium antagonists. It is a calcium channel blocking agent inhibiting the cellular influx of calcium associated with the plateau phase of

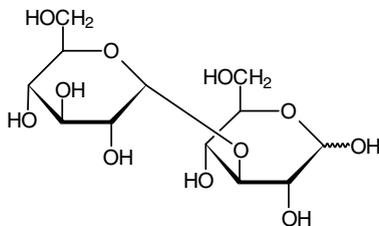

nigericin

the action potential. It acts as a vasodilator, reducing blood pressure and increasing coronary blood flow.

nigericin a 725 Da, open-chain macrotetrolide-like antibiotic, with many chiral centres, isolated from *Streptomyces hygroscopicus*. It forms stable complexes with monovalent cations, especially with K^+ ; these complexes are soluble in organic solvents, and thus nigericin can act as an ionophore for monovalent cations. It has some structural resemblance to **monensin**.

nigerose the disaccharide 3-*O*- α -D-glucopyranosyl-D-glucose.

night blindness or **nyctalopia** the inability to see in dim light or at night. It is due to deficiency of vitamin A or to degeneration of the **rod cells** in the retina of the eye, which primarily mediate vision in dim light.

NIH *abbr.* for National Institutes of Health (of the USA).

NIH shift or **hydroxylation-induced migration** an intramolecular migration that often occurs in the hydroxylation reactions of alkylaromatic compounds catalysed by certain mono- or dioxygenases, whereby a hydrogen atom or a substituent atom or group at the position of hydroxylation moves to an adjacent carbon atom in the aromatic ring. For example, in the hydroxylation of phenylalanine to tyrosine, catalysed by phenylalanine 4-monooxygenase (EC 1.14.16.1), the hydrogen atom at C-4 in the ring can be shown by tritium labelling to migrate to C-3. [After NIH, i.e. National Institutes of Health, where the discoverers were based.]

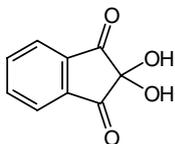

NIH-3T3 a continuous cell line established from NIH Swiss mouse embryo cultures. These cells are adherent, have fibroblast morphology, and are useful for DNA transfection and transformation studies.

Nijmegen breakage syndrome a human syndrome of mental retardation, increased susceptibility to cancer, immunodeficiency, and chromosomal instability. It is due to mutation in the gene (at 8q11) for **nibrin**, which is missing in cell lysates from patients. It is sometimes considered to be a variant of **ataxia telangiectasia**. [Named after Nijmegen, a city in the Netherlands where it was first identified.]

NIMR *abbr.* for National Institute for Medical Research (of the UK).

ninein *see centrosome*.

ninhydrin the *trivial name* of triketohydrindene hydrate; 2,2-dihydroxy-1,3-indanedione; a pale-yellow crystalline substance, useful as a sensitive chromogenic reagent for the detection and quantification of compounds containing free amino or imino groups. The common amino acids (and the free amino groups of peptides and proteins, and various other amino compounds) give a red, violet, or blue coloration, the shade depending somewhat on conditions, whereas the imino acids proline and hydroxyproline give a yellow colour. The partially reduced ninhydrin derivative, hydrindantin, is often added to the reagent solution, as it reacts with free ammonia that is formed as a side product, and in combination with ninhydrin forms the coloured product, thus enhancing the sensitivity of the reaction.

**nitric oxide**

NIPK *abbr.* for neuronal cell death-inducible protein kinase; *other name:* tribbles homologue protein 3 (*abbr.:* TRB3). One of three mammalian homologues of the *Drosophila* protein **tribbles**. It contains 354 amino acids, inhibits Akt/PKB – a key component of insulin receptor signalling – and its expression in liver is increased by fasting. TRB1, TRB2, and TRB3 share 45% amino acid sequence homology and strongly resemble tribbles.

Nir *symbol* for the ribonucleoside ribosylnicotinamide.

NIS *abbr.* for Na^+/I^- symporter. *See iodide pump*.

nisin a pore-forming toxin produced by the bacterium *Lactococcus lactis*. It has a molar mass of 5.8–6.3 kDa and creates opening in the affected membrane that permit passage of small solutes. It is used commercially for protection of foods against bacterial infection. In the TC system it has number 1.C.20.

Nissl substance a *collective term* for the dense regions of granular endoplasmic reticulum and free polysomes observable by microscopy within the cytoplasm of the cell body of vertebrate neurons. [After Franz Nissl (1860–1919), German neuropathologist, who first observed it.]

NIT domain *abbr.* for nitrate- and nitrite-sensing domain; a protein domain (≈ 250 amino acids, with several conserved charged residues) that is present in various receptor components of signal-transducing pathways in a variety of bacterial species. It may be intracellular or extracellular and lies between two transmembrane segments. It is predicted to form 10 α helices.

nitrate 1 the NO_3^- ion, derived from nitric acid. **2** any salt or ester of nitric acid.

nitrate assimilation an *alternative term* for assimilatory nitrate reduction; *see nitrate reduction*.

nitrate dissimilation an *alternative term* for dissimilatory nitrate reduction; *see nitrate reduction*.

nitrate reductase 1 any of the enzymes **nitrate reductase (NADH)** (EC 1.6.6.1), **nitrate reductase (NAD(P)H)** (EC 1.6.6.2), or **nitrate reductase (NADPH)** (EC 1.6.6.3) that reduce nitrate to nitrite coupled to the oxidation of the coenzymes indicated. They are widespread among plants and microorganisms, where they participate in assimilatory nitrate reduction. All are flavoproteins, usually containing one atom of molybdenum per molecule. **2** the microbial enzyme, nitrate reductase (EC 1.7.99.4), that reduces nitrate to nitrite coupled to the oxidation of various electron donors in dissimilatory nitrate reduction. **3** the microbial enzyme, **nitrate reductase (cytochrome)** (EC 1.9.6.1), that reduces nitrate to nitrite coupled to the oxidation of a ferrocyanochrome to the corresponding ferricytochrome. *See also nitrate reduction*.

nitrate reduction any reaction or sequence of reactions in which nitrate ion is converted to other less highly oxidized inorganic nitrogenous substances, e.g. to nitrite ion, nitrous oxide, dinitrogen, ammonium ion, or amino acids. In enzymology the term is restricted to the enzymic reduction of nitrate ion to nitrite ion, catalysed by a **nitrate reductase** enzyme. In biology, nitrate reduction is of two types, distinguishable by the purposes served and by the enzymes involved. **assimilatory nitrate reduction** is the process occurring in higher plants, algae, and fungi, in which nitrogen from nitrate is converted into organic nitrogen-containing compounds, via the probable reaction sequence: nitrate \rightarrow nitrite \rightarrow [hyponitrite] \rightarrow hydroxylamine \rightarrow ammonium \rightarrow amide group of glutamine \rightarrow amino acids, etc. **dissimilatory nitrate reduction** or **nitrate respiration** is the process occurring in some microorganisms under anaerobic conditions in which nitrate functions as a terminal electron acceptor in respiratory metabolism. The nitrogen may either be converted to ammonium (which is not assimilated), a process designated **ammonification of nitrate**, or be converted to various gaseous compounds such as nitric oxide, nitrous oxide, and/or dinitrogen, a process designated **denitrification**. *Compare nitrification*.

nitrene the chemical entity NH or any of its substitution derivatives. It contains an electrically neutral mono-coordinate nitrogen atom with four nonbonding electrons; two of these electrons are paired while the other two have spins that may be either antiparallel (singlet state) or parallel (triplet state). *Other names:* azacarbene; azene; imene; imine radical.

nitric oxide nitrogen monoxide; NO; a colourless gas, only slightly

soluble in water, that reacts readily with O₂ to form nitrogen dioxide, NO₂; it can form the stable cation NO⁺. It accounts for the action of endothelium-derived relaxing factor (EDRF). Nitric oxide is a biogenic messenger with potent actions including vasodilation, inhibition of platelet aggregation, and reduction of endothelium adhesion; it also has anticoagulant and fibrinolytic actions. It is formed biosynthetically from L-arginine by **nitric-oxide synthase** in most mammalian tissues in varying amounts, including vascular endothelial cells, the central and peripheral nervous system, immune cells, lung, or liver. It activates guanylate cyclase, producing cyclic GMP. It is oxidized to nitrite, then to nitrate, which is present in the blood.

nitric-oxide synthase EC 1.14.13.39; *abbr.*: NOS; *systematic name*: L-arginine,NADPH:oxygen oxidoreductase (nitric-oxide-forming). An enzyme that catalyses a reaction between L-arginine, NADPH, and O₂ in which citrulline, NADP⁺, and nitric oxide are formed; heme, FAD, FMN, and tetrahydrobiopterin are required as cofactors; the heme centre has the spectral properties of a cytochrome P450; N^ω-hydroxy-L-arginine is an intermediate, and acts as a substrate for the enzyme. Three isoforms are known: **nNOS**, of neuronal tissues, and **eNOS**, of vascular endothelial cells, are both expressed constitutively and are Ca²⁺-dependent; **iNOS**, inducible in macrophages and liver cells, is not Ca²⁺-dependent, but binds calmodulin with extremely high efficiency. All have consensus sequences for the binding of NADPH, FAD, FMN, and calmodulin, and a phosphorylation site for cyclic-AMP-dependent protein kinase A; eNOS has an N-terminal consensus sequence for myristoylation. Inhibitors include L-N^ω-(1-iminoethyl)ornithine, N^G-monomethyl-L-arginine, N^G-nitro-L-arginine.

nitrification the process by which certain soil bacteria (nitrifying bacteria) oxidize ammonium ions in decomposing organic material into nitrate ions. *Nitrosomonas* spp. first convert ammonium to nitrite, and *Nitrobacter* spp. then oxidize nitrite to nitrate. Most higher plants can assimilate nitrate much more readily than they can ammonium. *Compare* denitrification.

nitrify 1 (of nitrifying bacteria) to oxidize ammonium to nitrate. **2** to treat (soil) with nitrates. —**nitrified** or **nitrifying adj.**

nitrifying bacteria obligately aerobic bacteria that are capable of oxidizing ammonium to nitrite, and nitrite to nitrate. *See* nitrification. *Compare* denitrifying bacteria.

nitrite 1 the NO₂⁻ ion, derived from nitrous acid. **2** any salt or ester of nitrous acid.

nitrite reductase 1 the enzyme **nitrite reductase (NAD(P)H)** (EC 1.6.6.4) that reduces nitrite to ammonium coupled to the oxidation of either NADH or NADPH. It is a flavin-dependent enzyme that also contains **siroheme**; it participates in assimilatory **nitrate reduction** in higher plants, algae, fungi and bacteria. **2** the enzyme **nitrite reductase (cytochrome)** (EC 1.7.2.1) that reduces nitrite to nitric oxide coupled to the oxidation of ferrocyclochrome *c* to ferricytochrome *c*. It is a cuproprotein and participates in denitrification processes in some microorganisms. **3** the enzyme **ferredoxin–nitrite reductase** (EC 1.7.7.1) that reduces nitrite to ammonium coupled to the oxidation of reduced ferredoxin; the enzyme in spinach leaves contains one molecule of siroheme and one iron–sulfur [2Fe–2S] cluster per molecule. It participates in assimilatory nitrate reduction, the reduced ferredoxin being derived from the light reactions of photosynthesis. **4** the microbial enzyme, nitrite reductase (EC 1.7.99.3), that reduces nitrite to nitric oxide coupled to the oxidation of various electron donors in dissimilatory nitrate reduction; the enzymes from *Achromobacter cycloclastes* and *Pseudomonas denitrificans* contain copper.

nitro the chemical group –NO₂ in a molecule of an organic compound.

nitro+ prefix (*in chemical nomenclature*) **1** indicating the presence of a **nitro** group in an organic compound. **2** (*in chemical technology*) indicating that a chemical compound is a nitrate ester.

Nitroblue Tetrazolium *see* Nitrotetrazolium Blue.

nitrogen 1 *symbol*: N; a nonmetallic element of group 15 of the IUPAC **periodic table**; atomic number 7; relative atomic mass 14.0067. There are two natural stable nuclides of relative masses 14 (99.635 atom percent) and 15 (*see* **nitrogen-15**); its commonest valences are iii and iv. Nitrogen occurs naturally in the form of di-

atomic molecules of the gas dinitrogen (see below) and in combined form in numberless organic molecules in all forms of life. *See also* **nitrogen-13**. **2** **dinitrogen** or **molecular nitrogen** *symbol*: N₂; a diatomic nonflammable gas. It constitutes 75.5% by mass, or 75.06% by volume, of the Earth's atmosphere, and undergoes exchange with organically combined nitrogen via the processes of the **nitrogen cycle**. Liquid nitrogen, b.p. 77.36 K, is commonly used as a coolant or freezing agent.

nitrogen-13 the artificial radioactive nitrogen nuclide ¹³7N. It emits a positron (β⁺-particle) (1.19 MeV max.) and no gamma radiation; it has a half-life of 9.96 min.

nitrogen-15 heavy nitrogen; the stable, naturally occurring nitrogen nuclide ¹⁵7N; relative abundance in nitrogen 0.365 atom percent. It is extensively used as a tracer in studies of nitrogen metabolism and in **nuclear magnetic resonance**.

nitrogenase an enzyme complex that catalyses the ATP-dependent fixation of atmospheric nitrogen, summarized by the equation:

Depending on the bacterial species, the electrons may be donated either by reduced ferredoxin (this enzyme is EC 1.18.6.1) or flavodoxin (EC 1.19.6.1). For each molecule of nitrogen reduced, at least one molecule of hydrogen is released. Either type of nitrogenase will use ferredoxin or flavodoxin as donor *in vitro*. Nitrogenase consists of two oxygen-sensitive components, known as MoFe protein (*other names*: component I; dinitrogenase; molybdoferredoxin) and Fe protein; (*other names*: component II, dinitrogenase reductase; azoferredoxin). Component I is a tetramer made up of two polypeptide chains of about 50 and 60 kDa, each present twice; the tetramer contains two P-clusters (Fe₈S₇) and two Fe-Mo cofactors (*abbr.*: FeMo-co). The Fe-Mo cofactor has the formula Fe₇MoS₉. The Mo is coordinated by 3 sulfide ions, a histidine N and 2 oxygen atoms of homocitrate. The extremely oxygen-sensitive component II is a dimer of identical, ~30 kDa, polypeptide chains; each binding a molecule of ATP. The two subunits of the dimer are bridged by a single [4Fe–4S] cluster. Electrons from a donor, such as NADPH, are transferred, via reduced ferredoxin or flavodoxin, to component II. Then, in the presence of Mg²⁺ they are passed to component I, with concomitant hydrolysis of 4–5 molecules of ATP per two electrons transferred. Eventually they are used to reduce dinitrogen to ammonium. Nitrogenase also catalyses ATP-dependent partial reductions of some other small-molecules that are isoelectronic with dinitrogen, e.g. ethyne, azide, cyanide, and dinitrogen monoxide. The reduction of ethyne to ethene, which can be measured by gas chromatography is used as a convenient assay for nitrogenase activity. Alternative nitrogenases are known that contain vanadium instead of molybdenum, or just iron as the only transition metal; these appear to be structurally and functionally analogous to the molybdenum-containing nitrogenase although they produce more H₂ per N₂ reduced.

nitrogenase reductase *another name for* dinitrogenase reductase; i.e. component II of nitrogenase.

nitrogen balance 1 (*in physiology*) the **balance** (def. 1) of the nitrogen content of the nutrients and the excretory products of an organism. **2** (*in agriculture*) the net loss or gain of the nitrogen content of soil that results from removal of nitrogen by cropping, leaching, etc. and addition of nitrogen by nitrogen fixation or addition of nitrogenous fertilizers.

nitrogen base *an alternative term for* nitrogenous base.

nitrogen cavitation *an alternative name for* pressure homogenization.

nitrogen cycle the series of chemical processes by which various inorganic and organic nitrogenous compounds are interconverted and maintained in equilibrium in the biosphere. It consists essentially of **nitrogen fixation**, **nitrification**, and **denitrification**, together with assimilatory and dissimilatory **nitrate reduction** and the interconversion of nitrogenous organic matter and ammonium. Individual reactions may be effected by microorganisms, plants, or animals, with contributions from nonbiological processes such as manufacture of nitrogenous fertilizers, the action of lightning, and emission of combustion products.

nitrogen equilibrium the state of **nitrogen balance** (def. 1) when nitrogen intake equals nitrogen excretion.

nitrogen fixation any biological or nonbiological process that converts atmospheric dinitrogen into inorganic nitrogenous compounds; the meaning is often extended to include the biological assimilation of ammonium so produced. Biological nitrogen fixation occurs by the action of the enzyme **nitrogenase**, found in certain species of bacteria – the nitrogen-fixing bacteria.

nitrogen mustard any of a group of bis(2-chloroalkyl)amines, as typified by the volatile base bis(2-chloroethyl)ethylamine, $\text{CH}_3\text{-CH}_2\text{-N}(\text{CH}_2\text{-CH}_2\text{Cl})_2$, a nitrogen-containing analogue of **mustard gas**. They are potent alkylating agents, vesicants, and mutagens. They cross-link DNA chains and have been used as immunosuppressive and antineoplastic agents.

nitrogenous 1 of or relating to **nitrogen 2** of or relating to any substance containing nitrogen in combined form.

nitrogenous base or **nitrogen base** a generic term for ammonia or any trivalent compound of nitrogen that can be regarded as a derivative of ammonia; all except quaternary ammonium compounds are weakly basic in character. In biochemistry, the term usually denotes any purine or pyrimidine; now generally shortened to base.

nitrogen regulatory protein *abbr.*: NR protein; any of several proteins of a regulatory system for transcriptional control of the glutamine-ammonia ligase, and for its regulation at the structural level. Transcriptional regulation is mediated by the proteins NR_I and NR_{II}. NR_I, when phosphorylated, acts as a transcriptional activator of the gene *glnA*; NR_{II} is a kinase that converts NR_I to NR_I-P, the phosphorylated, active form. Another protein, P_{II}, prevents this phosphorylation, thereby preventing transcriptional activation. P_{II} can be uridylylated at Tyr⁵¹ to P_{II}-UMP by a **uridylyl transferase**, and then does not inhibit NR_I phosphorylation, so activating transcription. This occurs when the level of nitrogen is low. Regulation of glutamate-ammonia ligase at the structural level involves adenylation by adenylyl transferase, which inactivates it. Adenylyl transferase is activated by P_{II}. In the presence of P_{II}-UMP, adenylyl transferase is inactivated, and glutamate-ammonia ligase reverts to a non-adenylylated, active form. Uridylylation of P_{II} thus results in activation of transcription of glutamate-ammonia ligase, and its activation at the structural level.

nitroglycerin 1,2,3-propanetriol trinitrate; a compound that is used industrially in the manufacture of dynamite, and pharmacologically as an antianginal and coronary vasodilator. Its action in the latter case results from its conversion to **nitric oxide**.

nitrophenyl a group that is linked to a variety of compounds to form artificial substrates for enzymes. The nitrophenol released by the enzyme action can then be measured spectrophotometrically at 400 nm (4-nitrophenol) or 420 nm (2-nitrophenol) to follow the enzyme reaction, the esterified form having a maximal absorption at a much lower wavelength. Typical substrates are 4-nitrophenylacetate (for carboxylesterase, lipase), 4-nitrophenyl-*N*-acetylgalactosaminide (galactosaminidase), 4-nitrophenyl-*N*-acetylglucosaminide (glucosaminidase), and 2-nitrophenylbutyrate (cholinesterase).

nitrophorin *abbr.*: NP; a monomeric hemoprotein (≈ 20 kDa) secreted in saliva of the blood-sucking reduviid bug *Rhodnius prolixus*. There are four nitrophorins (NP 1 to 4), which are homologous and contain a conserved eight-stranded beta barrel. They carry nitric oxide, which causes smooth muscle relaxation and vasodilation in the host. They also bind histamine and reduce the inflammatory and immune responses in the host. NP2 (also called prolixin-S) inhibits activation of clotting factor X.

nitroprusside test a test for free thiol groups based on the red coloration given on reaction of thiol-containing compounds with ammoniacal sodium nitroprusside, sodium nitrosopentacyanoferrate(III), $\text{Na}_2[\text{Fe}(\text{CN})_5\text{NO}]$. Nitroprusside also reacts with ketones and is used in tests for ketone bodies in urine. The proprietary Acetest tablets contain a mixture of glycine, sodium nitroprusside, disodium phosphate, and lactose. In the presence of glycine, acetoacetate or acetone forms a blue–purple colour. A positive reaction indicates the presence of ≥ 5 mg dL⁻¹ and 10 mg dL⁻¹ for urine and blood respectively.

nitroso+ a variant form of **nitroso+** (before a vowel).

***N*-nitrosamide** any organic compound in which a **nitroso** group is

attached to an amide nitrogen, e.g. *N*-methyl-*N*-nitrosoarea. See also ***N*-nitrosamine**.

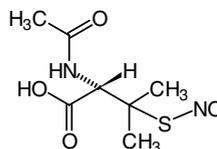

***N*-nitrosamidine** any organic compound in which a **nitroso** group is attached to an amidine nitrogen, e.g. *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine. See also ***N*-nitrosamine**.

***N*-nitrosamine** any organic compound of general formula R₁R₂NNO. They are stable compounds formed by the action of nitrous acid on secondary amines with concurrent monodealkylation, and also on some tertiary amines. Most nitrosamines are strongly carcinogenic and their metabolites are strong mutagens. ***N*-nitrosamides** and ***N*-nitrosamidines** are unstable nitroso compounds that decompose in neutral or alkaline conditions to produce powerful alkylating agents. They are widely used as experimental mutagens. They are carcinogenic in any tissue with which they come into contact.

nitroso the chemical group –NO in a chemical compound.

nitroso+ or (before a vowel) **nitros+** prefix (in chemical nomenclature) indicating the presence of a **nitroso** group in a chemical compound; in *C*-nitroso compounds the –NO is attached to carbon (e.g. nitrosobenzene) and in *N*-nitroso compounds it is attached to nitrogen.

***S*-nitroso-*N*-acetylpenicillamine** *abbr.*: SNAP; an *S*-nitrosothiol reagent that stimulates guanylate cyclase and mimics the action of nitric oxide.

S-nitroso-*N*-acetyl-d-penicillamine

***S*-nitrosogluthione** a nitrosating reagent that breaks down to nitric oxide and a glutathione radical. It induces the cellular effects of nitric oxide, including smooth muscle relaxation and inhibition of platelet aggregation.

Nitrotetrazolium Blue or **Nitroblue Tetrazolium** a dye very similar in structure to Tetrazolium Blue (see **tetrazolium salt**), differing only in that each of the two tetrazolium groups has a nitrophenyl group in place of a phenyl group.

nitrous acid the very unstable monobasic acid HNO₂. It reacts with amines, including purine and pyrimidine amines, to form the corresponding hydroxy compounds, and is thus mutagenic.

nitroxide the divalent group =N–O• in a molecule of an organic compound. It has an unpaired electron, and is useful in spin-labelling, its derivatives being stable free radicals.

NK cell *abbr.* for natural killer cell; a large granular lymphocyte that recognizes structures on the surface of virally infected cells, which it kills, probably through the mediation of a **perforin**.

NKSF *abbr.* for NK stimulating factor. See **interleukin 12**.

***N*le** symbol for the α -amino acid norleucine (now known as 2-amino-hexanoic acid, symbol: Ahx).

NLM *abbr.* for National Library of Medicine.

NLP *abbr.* for natural language processing.

NLS *abbr.* for nuclear localization signal.

nm symbol for nanometre.

nM symbol for nanomolar.

NMD *abbr.* for nonsense-mediated decay.

NMDA *abbr.* for *N*-methyl-D-aspartate.

NMDA receptor see **glutamate receptor**.

NMN *abbr.* for nicotinamide mononucleotide.

nmol symbol for nanomole.

NMP *abbr.* for any (unknown or unspecified) nucleoside monophosphate in which the phosphate group is esterified at the 5' position of the glycoside moiety.

NMR or **nmr** *abbr.* for nuclear magnetic resonance.

Nn symbol for the nonyl group.

Nno *symbol* for the nonanoyl group.

nNOS *see* **nitric-oxide synthase**.

NNRTI *abbr.* for non-nucleoside reverse transcriptase inhibitor.

No *symbol* for nobelium.

nociceptin *an alternative name for orphanin FQ*.

nociceptive causing pain or injury; reacting to a painful stimulus.

nociceptor any receptor that reacts to painful (i.e. nociceptive) stimuli; a pain-sense organ.

Nod a family of human intracellular proteins involved in detection of invasive bacteria and activation of the NF- κ B transcription factor pathway. In epithelial cells, Nod1 is essential for sensing intracellular Gram-negative bacteria through a tripeptide motif in the bacterial peptidoglycan.

NodD a transcription factor of *Rhizobium* bacteria that, on binding an inducer secreted by infected root cells in a host plant, induces *nod* genes in the bacterium.

node **1** a knob, lump, or swelling; a constriction, especially when serially repeated (along the length of something). **2** (*in botany*) the point on a stem to which a leaf or a lateral branch is attached. **3** (*in physics*) a point of zero or minimum displacement in a standing wave or a system of such waves. *See also* **node of Ranvier**. —**nodal** *adj.*

node of Ranvier any of the constrictions in the myelin sheath that occur at regular intervals along the length of a myelinated nerve fibre. [After Louis Antoine Ranvier (1835–1922), French pathologist.]

Nod factor any bacterial product, made by enzymes encoded in *nod* genes of *Rhizobium* species, that directs nodulation in the host plant. Nod factors are lipopolysaccharides consisting of a short linear backbone of β 1-4-linked *N*-acetylglucosamine residues, the first of which is usually *N*-acylated by a C₁₆, C₁₈, or C₂₀ fatty acid of varying levels of unsaturation. The factors cause rapid cell division in infected root cortical cells of legumes to form the nodules involved in nitrogen fixation.

nod gene any gene in *Rhizobium* bacteria that is responsible for early nodule formation in nitrogen-fixing plants. The expression of *nod* genes depends on an inducer (e.g. genistein or daidzein) from the host and an endogenous transcription factor (NodD) in the bacterium that is a receptor for the inducer. Many *nod* genes encode enzymes that direct the synthesis of bacterial **Nod factors** responsible for inducing nodulation in the host.

NOD mice *abbr.* for nonobese diabetic mice.

nodoc a name sometimes used for **anticodon** (formed by reversing the letters of the word codon).

nodulation factor a lipooligosaccharide secreted by *Rhizobium* species as an extracellular signal that induces nodule formation in the roots of a host legume plant. It consists of a linear chain of 3–6 (usually 5) *N*-acetylglucosamine residues joined β 1-4 and with a (usually C₁₈) fatty acid attached to the N atom of C2 of the nonreducing end.

nodule bacterium or **nodule-forming bacterium** a common name for any bacterium of the genus *Rhizobium*, found as endosymbionts in root nodules. The bacterium specifically infects root cells of Leguminosae, and causes the development of **root nodules**, in which it loses its outer membrane and becomes dependent on plant metabolism. It is then morphologically differentiated from the free-living form and known as a bacteroid. In return it fixes nitrogen for the plant. *See* **nitrogenase**.

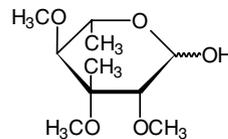

nodulin any protein that is produced within root nodules of nitrogen-fixing plants in response to **Nod factors** secreted by *Rhizobium* bacteria in infected cells. Their roles include acting as membrane channels for transport across the symbiosome membrane; as enzymes involved in metabolism of carbon and nitrogen; or in establishing a low-oxygen environment (e.g. leghemoglobin). Nodulins are described as early or late depending on when they are expressed during nodule formation.

NOE *abbr.* for nuclear Overhauser effect.

NOESY *abbr.* for nuclear Overhauser effect spectroscopy. *See* **NMR**.

nogalamycin an antitumour antibiotic material obtained from *Streptomyces nogalater*. It contains the carbohydrate component **nogalose**.

nogalose 6-deoxy-3-*C*-methyl-L-mannose 2,3,4-trimethyl ether; a carbohydrate component of **nogalamycin**.

noggin a dorsaling factor localized to **Spemann's organizer** in *Xenopus laevis* embryos.

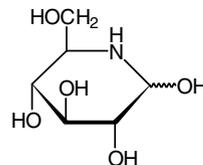

Nogo an abundant **myelin protein** that is produced by oligodendrocytes in the central nervous system. Like myelin-associated glycoprotein it inhibits neuronal regeneration. It has two transmembrane segments and an extracellular loop of 66 residues (sometimes called Nogo-66) that binds to the **Nogo receptor**.

Nogo receptor a phosphatidylinositol (PI)-anchored peripheral cell surface protein of neurons in the central nervous system. It binds the 66-residue extracellular loop of **Nogo**, and also myelin-associated glycoprotein and oligodendrocyte myelin glycoprotein. *See* **myelin protein**.

noise any undesired disturbance in the signal from an instrument, or other system, that degrades the amount of useful information extractable. *Compare* **signal-to-noise ratio**.

noise analysis the technique whereby the amplitude and frequency of random fluctuations in the membrane potential of an excitable cell are used to investigate changes in conductance of single ion channels induced, e.g., by a drug or neurotransmitter.

nojirimycin any of a group of carbohydrate-like alkaloids or imino sugars originally found in a *Streptomyces* filtrate but also found in plants such as *Morus alba* and *Angylocalyx pynaertii*. Nojirimycins are inhibitors of glycosidases and glycosyltransferases. Derivatives such as *N*-butyldeoxynojirimycin inhibit: (1) α -glucosidase, involved in the processing of *N*-linked glycoprotein chains; and (2) glucosylceramide transferase, which catalyses the first step in one of the biosynthetic pathways leading to glycosphingolipids and gangliosides.

nominal describing an approximate value assigned to some quantity as a guide to its real value (which may vary according to circumstances).

nomogram or **nomograph** any chart or diagram consisting of scaled lines and used for facilitating calculations, especially one consisting of three lines scaled for different related variables such that a straight line joining chosen values of two variables will intersect the third scale line at the related value of the third variable. —**nomography** *n.*; **nomographic** *adj.*

non+ **1** *prefix* denoting negation; absence of; opposite or reverse of; e.g. nonabsorbable, nonacylated, nonconductor, noncyclic, nonmetal, nonspecific. **2** a variant form of **nona+** (sometimes before a vowel).

nona+ or (sometimes before a vowel) **non+** *comb. form* denoting nine, ninefold, nine times.

nonacos+ *comb. form* denoting twenty-nine, twenty-nine fold, twenty-nine times.

nonacosane a linear C₂₉ hydrocarbon, CH₃–[CH₂]₂₇–CH₃.

nonactin a neutral macrotetrolide antibiotic produced by several *Streptomyces* spp. It transports alkali cations through membranes

with high selectivity for K^+ , but also for NH_4^+ . It is one of a related series including monactin, dinactin, and trinactin.

nonadeca+ *comb. form* denoting nineteen, nineteen fold, nineteen times.

nonaethyleneglycol mono-*n*-dodecyl ether a nonionic $C_{12}E_9$ detergent; *see* C_xE_y .

nonanoate or **pelargonate 1** the anion $CH_3-[CH_2]_7-COO^-$, derived from nonanoic acid (i.e. pelargonic acid). **2** any salt or ester of nonanoic acid.

nonanoyl or **pelargonoyl** *symbol*: Nno; the univalent acyl group $CH_3-[CH_2]_7-CO-$, derived from nonanoic acid (i.e. pelargonic acid).

nonaqueous lacking water; applied especially to solvents whether polar or nonpolar.

nonbonding electrons *an alternative name for lone pair*.

noncoded amino acid or **uncoded amino acid** any α -amino-acid residue occurring in a polypeptide or protein for which no codon exists: e.g., γ -carboxyglutamic acid, hydroxylysine, hydroxyproline, oxyproline. Residues of these amino acids are formed from residues of the corresponding coded amino acids by post-translational modification of the polypeptide chain.

noncoding region or **noncoding sequence** any segment of a nucleic acid molecule for which there is no recognized gene product; it may sometimes play a structural role in the organization of the molecule. *See also* intron.

noncoding strand or **template strand** a term that is variously, and confusingly, applied to either of the two strands of genomic duplex DNA. It is now the term recommended for denoting the strand that is complementary in its sequence of bases to messenger RNA (mRNA) transcribed from the DNA; it thus functions as the template for synthesis of mRNA, which then contains the sequence present in the **coding strand** of duplex DNA (except for uracil in RNA serving in place of thymine in DNA). In some bacteria and viruses, alternate segments of both strands of duplex DNA may be noncoding. *Other names*: antisense DNA; antisense strand; complementary strand; minus strand; transcribing strand. *Compare* complementary DNA.

noncompetitive antagonism (*in pharmacology*) the phenomenon occurring when agonist and antagonist can be bound simultaneously, in which antagonist binding reduces or prevents the action of the agonist; e.g. channel block of the nicotinic receptor, or inhibition by adrenoceptor antagonists of the response to tyramine.

noncompetitive inhibition inhibition of an enzyme in which inhibition results from binding of the inhibitor at a different site on the enzyme surface from that at which the substrate binds, without interference with substrate binding.

nonconjugative plasmid any plasmid that cannot bring about transfer of DNA by conjugation.

nonconservative replication of DNA or **dispersive replication of DNA** *see* replication of DNA.

noncoupled solute translocation the translocation of a solute across a membrane that is not coupled to the translocation of another solute, in either the same or the opposite direction. *See* facilitated diffusion, uniport.

noncovalent describing an interaction between atoms and/or molecules that does not involve the formation of a covalent bond between them.

noncyclic electron flow (*in photosynthesis*) *see* photophosphorylation.

noncyclic photophosphorylation *see* photophosphorylation.

nondiffusible material material that is not diffusible in the restricted sense of its being incapable of passing through a diffusion barrier, especially through a semipermeable membrane used in dialysis. *Alternative terms recommended by IUPAC*: retentate, dialysis residue, or residue.

nondisjunction (*in genetics*) failure of a chromosome pair to separate at the first meiotic division or for two chromatids to separate at the second meiotic division, so that both daughter chromatids pass into the same daughter cell. Autosomal trisomies are thought to originate from fertilization of eggs with two daughter chromatids.

nondissymmetric a term formerly used to describe an achiral mol-

ecule that possesses an alternating axis of symmetry but that (unlike a symmetric molecule) lacks a simple axis of symmetry; the converse of **dissymmetric**. An important example is **citric acid**, which has a one-fold alternating axis but no simple axis; thus its pair of carboxymethyl groups on carbon-3 are not geometrically equivalent. *See also* prochiral.

nonelectrolyte any substance that is neither an electrolyte nor a conductor of electrons.

nonessential amino acid any amino acid that can be synthesized in the body in an amount corresponding to need, and hence for which there is not an absolute dietary requirement. The extent to which a particular amino acid is non-essential in any one species depends on the stage of development and physiological state of the subject. The following L-amino acids are non-essential for the maintenance of nitrogen equilibrium in an adult human: alanine, arginine, asparagine, aspartic acid, cysteine, glutamic acid, glutamine, glycine, histidine, hydroxyproline, proline, serine, and tyrosine. Arginine and histidine are, however, essential in growing children.

nonesterified fatty acid *abbr.*: NEFA; **1** *an alternative name for free fatty acid*. **2** *a collective term for the total of free fatty acids in a sample, especially of blood*.

nonheme iron or (*esp. Brit.*) **nonhaem iron** any iron in a biological sample or structure that is not chelated in heme groups. In nonheme-iron proteins, the iron is often present in iron-sulfur clusters.

nonhistone protein or **nonhistone chromosome protein** any member of a highly heterogeneous group of 10–150 kDa tissue-specific proteins associated with DNA in cell nuclei. They are thought to play a part in the control of gene expression. *See also* high mobility group proteins.

nonhomologous (of chromosomes or chromosome segments) not homologous (def. 4).

nonideal describing any gas or solution that does not behave like an ideal gas or ideal solution, respectively. —**nonideality** *n*.

Nonidet P-40 *the proprietary name for a nonionic detergent, (octylphenoxy)-polyethoxyethanol, used for solubilizing membrane proteins*. It is no longer commercially available but can be replaced with IGEPAL CA-630, which is chemically identical. *Compare* Triton.

non-insulin-dependent diabetes *an alternative name for type 2 diabetes mellitus*.

noninvasive 1 not invasive. **2** (*of a clinical investigative technique or procedure*) carried out without penetrating the skin.

nonionic having or yielding no ions; the term is used especially of nonionic detergents.

nonionic detergent any detergent whose molecules cannot ionize.

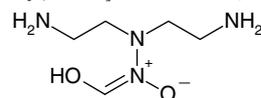

non-lactose-fermenter *a jargon term for any genus, species, or strain of microorganism that does not ferment lactose*.

nonmediated transport *an alternative name for unmediated transport*.

non-Newtonian fluid any fluid that does not conform to Newton's law of viscosity, i.e. one whose (coefficient of) viscosity is not independent of flow rate.

non-nucleoside reverse transcriptase inhibitor *abbr.*: NNRTI; an antiretroviral drug, used in AIDS therapy, that binds to the catalytic site of the HIV-1 reverse transcriptase, preventing RNA conversion to DNA. Owing to the rapid development of resistance, it is often used in combination with other drugs. NNRTIs have no activity against HIV-2. *Compare* nucleoside reverse transcriptase inhibitor.

nonoate A compound of structure $R_1R_2NN(O)=NOR_3$, which releases nitric oxide in water. Different derivatives have different rates of NO release e.g. DETA NONOate, (Z)-1-[2-(2-aminoethyl)-N-(2-ammonioethyl)amino]diazol-1-ium-1,2-diolate.

nonorthologous gene displacement during evolution, the displacement of a particular gene by an unrelated (i.e. nonorthologous) but functionally analogous gene.

nonose any **aldose** having a chain of nine carbon atoms in the molecule.

nonoverlapping code *see* **overlapping code**.

nonpenetrance (*in genetics*) the lack of the expected phenotype in individuals who are heterozygous for an autosomal dominant gene.

nonpermissive restrictive; not **permissive**.

nonpermissive cell any cell that does not support infection by a particular lytic virus; in a small percentage of instances the virus may transform a nonpermissive cell.

nonpolar 1 lacking polarity. **2** or **apolar** (*of a chemical group or substance*) lacking a significant permanent dipole moment.

nonpolar bond 1 any covalent bond that is not appreciably polarized. **2** (*sometimes*) *an alternative term for hydrophobic interaction*.

nonpolar solvent a *loose term denoting* any solvent with low ionizing power and hence low solvating power.

nonproductive binding or **dystopic binding** the binding of a substrate in an unreactive mode at the active site of an enzyme, leading to the formation of a nonproductive, or **abortive complex**.

nonproductive complex *an alternative name for abortive complex*.

nonprotein amino acid any amino acid that does not naturally occur as a constituent residue of proteins. Over 200 such amino acids are known to be produced in higher plants; although they often contribute to the nitrogen pool of the plants, their specific function is unknown. Non-protein amino acids also occur in animals, but to much less extent, the most prominent examples being **argininosuccinate**, **citrulline**, and **ornithine**.

nonprotein nitrogen *abbr.*: NPN; the part of the nitrogen content of a substance (or fluid) that is not contained in the proteins present. The term is used especially of blood or serum, wherein urea accounts for about half the total NPN.

nonradioactive having no radioactivity; in practice the term is often used to refer to substances having a normal or natural nucleidic composition, ignoring any contribution from minimal proportions of naturally occurring radionuclides such as the carbon-14 content of natural organic materials.

nonradioactive labelling any method for coupling a distinctive and detectable molecular entity to a DNA, RNA, protein, or other molecule, that permits detection of this molecule by nonradioactive means. Such labelling might involve, for example, the introduction of haptens that can subsequently be detected by anti-hapten antibodies coupled to an enzyme that can be detected by colorimetric, fluorimetric, or chemiluminescent methods.

nonradioactive tracer (*sometimes*) a labelled substance that can be detected and estimated by virtue of some property other than radioactivity (such as colour, fluorescence, or a difference in stable-isotope ratio).

nonreducing end the end of a linear oligosaccharide or polysaccharide that does not carry a potential hemiacetal or hemiketal (i.e. reducing) group.

nonribosomal peptide synthesis *abbr.*: NRPS; the type of peptide synthesis employed by actinomycetes, bacilli, and filamentous fungi in manufacturing complex peptide antibiotics, such as cyclosporin, gramicidin, erythromycin, and vancomycin. No mRNA, tRNA, or ribosomes are required. Instead, a multimodular nonribosomal peptide synthetase determines the composition and sequence of the peptide to be synthesized.

nonsecretor *see* **secretor gene**.

nonselectively labelled describing a labelled compound in which the position(s) and the number of the labelling nuclide(s) are both undefined.

nonsense codon or **nonsense triplet** any one of the nucleotide triplets UAA (ochre), UAG (amber), and UGA (opal) that signal termination of translation and release of the polypeptide chain from the site of synthesis. A codon that is nonsense in one strain of an organism may nevertheless code for an amino acid in another strain containing an appropriate suppressor gene (*see* **nonsense suppressor**). UGA sometimes codes for selenocysteine and, in mitochondria, for Trp. In mitochondria AGA is a nonsense codon rather than UGA. *Compare* **missense codon**.

nonsense-mediated alternative splicing *abbr.*: NAS; a form of alternative splicing of a pre-mRNA containing a nonsense (i.e. stop) mutation in an internal exon, in which alternative splicing occurs so

as to produce a stable mRNA that lacks the mutation. *Compare* **nonsense-mediated decay**.

nonsense-mediated decay the selective degradation in cytoplasm of eukaryotic mRNA that contains a premature stop codon. This reduces the production of abnormally truncated and potentially harmful proteins. The decay is triggered by a surveillance complex. *See* **mRNA surveillance**.

nonsense mutation any mutation in a DNA molecule that results in an alteration of a sense codon to a **nonsense codon** in the mRNA transcript, the translation of which leads to the formation of a truncated polypeptide gene product. *Compare* **missense mutation**.

nonsense suppressor any tRNA molecule that is able to insert an amino-acid residue into a growing polypeptide chain at a nonsense codon in an mRNA molecule. It has an altered anticodon, produced as a result of a **suppressor mutation**.

nonshivering thermogenesis *abbr.*: NST; a mechanism of rapid heat production in response to cold that does not involve muscular contractions. It is important during the neonatal period, during cold adaptation of a number of small mammals, and during the arousal period of animals that hibernate. Heat is produced in the mitochondria of brown adipose tissue in response to the presence in the inner mitochondrial membrane of a specific 32 kDa protein. This protein uncouples the respiratory chain and is inducible by norepinephrine. It is known as **brown fat uncoupling protein**.

nonspecific serine/threonine protein kinase EC 2.7.11.1 a serine/threonine kinase that catalyses phosphorylation of several proteins, using ATP; other names **glycogen synthase *a* kinase**; **cAMP-dependent protein kinase**; **calcium-dependent protein kinase C**. It is activated by phosphorylation by cyclic AMP-dependent protein kinase.

nonsuppressible insulin-like activity *abbr.*: NSILA; **insulin-like activity** that is not suppressible by specific antisera to insulin. The activity is now attributed to **insulin-like growth factors**.

nonsynonymous mutation a nucleotide substitution in a protein-coding gene that results in an amino acid substitution in the translation product. The ratio of nonsynonymous to synonymous substitutions may be used to detect positive Darwinian selection.

nontranscribing strand (of duplex DNA) *see* **coding strand**.

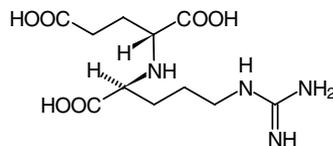

nonulose any **ketose** having a chain of nine carbon atoms in the molecule.

nyl *symbol*: Nn; the alkyl group CH₃[CH₂]₇CH₂-, derived from nonane.

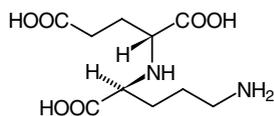

nyl glucoside *n*-nyl- β -D-glucopyranoside; a mild, nonionic detergent, CMC 6.5 mm. *Compare* **heptyl glucoside**, **hexyl glucoside**, **octyl glucoside**.

Noonan syndrome or **cardiofaciocutaneous syndrome** an autosomal dominant disorder in which cardiac anomalies are associated with short stature, facial abnormality, and webbed neck. It is associated with mutations in PTNP11 (protein tyrosine phosphatase 11). [After Jacqueline Noonan (1921-), US cardiologist.]

nopaline *N*-(1-carboxy-4-guanidinobutyl)glutamic acid; *N*²-(1,3-dicarboxypropyl)arginine; a rare amino-acid derivative that is produced by a certain type of crown-gall tissue (*see* **crown-gall disease**); one of a group of **opines**. The genes responsible for the synthesis of nopaline are part of the **T-DNA** from a **Ti-plasmid**.

nopalinic acid or **ornaline** *N*-(1-carboxy-4-aminobutyl)glutamic acid; *N*²-(1,3-dicarboxypropyl)ornithine; one of a group of **opines** found in plant tumours occurring in **crown-gall disease**.

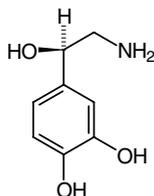

nopalinic acid

nor+ *prefix (in chemical nomenclature)* denoting **1** replacement of one side-chain methyl group by a hydrogen atom, e.g. norepinephrine, 19-nortestosterone. Replacement of two or three methyl groups is denoted by the prefix dinor+ or trinor+, respectively (in terpene nomenclature the prefix nor+ formerly denoted removal of all replaceable methyl groups; hence, e.g., 8,9,10-trinorbornane was formerly known as norbornane). **2** elimination of one methylene group from a chain or ring of carbon atoms; it is used especially for steroids, e.g. 23-nor-5 β -cholanoic acid, A-nor-5 β -androstane, norophthalmic acid. Elimination of two or three methylene groups is denoted by the prefix dinor+ or trinor+, respectively. **3** an isomer with an unbranched hydrocarbon chain, e.g. norleucine, norvaline; use discouraged.

noradrenaline *an alternative name for norepinephrine.*

noradrenergic (*sometimes*) **1** an (adrenergic) nerve cell that itself liberates noradrenaline (i.e. norepinephrine). **2** a cell or receptor that is stimulated preferentially by norepinephrine. —**noradrenergically** *adv.*

norepinephrine or **noradrenaline** or **levarterenol** (–)-(3,4-dihydroxyphenyl)-2-aminoethanol; a hormone secreted by the adrenal medulla, and a neurotransmitter in the sympathetic peripheral nervous system and in some tracts in the central nervous system. It is also the demethylated biosynthetic precursor of epinephrine in the adrenal medulla. It has a powerful lipolytic action, mediated by cyclic AMP, and is an agonist for **adrenoceptors**, inducing arteriolar constriction and raised systolic and diastolic arterial blood pressure.

R(–)-enantiomer

norepinephrine transporter or **noradrenaline transporter** an integral membrane protein of neuronal synapses that contains 12 transmembrane segments and is responsible for reuptake of most of the norepinephrine released at synapses. It is inhibited by cocaine, amphetamines, and tricyclic antidepressants, all of which cause features of **orthostatic intolerance**.

Norit *the proprietary name for a commercially produced activated carbon, useful as an adsorbent.*

norleucine *symbol:* Ahx or (*formerly*) Nle; 2-aminohexanoic acid; a non-protein α -amino acid. *See also* nor+ (def. 3).

norm+ *a variant form of normo+ (before a vowel).*

normal **1** not deviating from an established pattern; approximating to an average, or within the usual range (of values). **2** (*in organic chemistry*) *symbol:* n; (of a solution) containing one **equivalent** (def. 4) of a specified substance (of specified equivalence factor) in one litre of solution. Use now not recommended. **3** (*in organic chemistry*) a chemical compound that has an unbranched chain of carbon atoms; the names of such compounds may be prefixed by 'n', as in *n*-butane. However, this is not the currently recommended terminology. **4** (*in biology*) not diseased or not having been exposed to

an experimental procedure. **5** (*in mathematics*) (of a straight line or plane) at a right angle (to another straight line or plane).

normal distribution or **Gaussian distribution** any continuous frequency distribution of events, observations, etc. characterized by a symmetrical bell-shaped curve of the frequency of *x*, *f*(*x*), against the value of *x*, that is represented by the equation:

$$f(x) = [1/\sigma(2\pi)^{0.5}]e^{-(x-\mu)^2/2\sigma^2}$$

where μ is the mean and σ is the standard deviation.

normality (*in chemistry*) the chemical concentration of a solution expressed as the number of **equivalents** (def. 4) of a specified substance (of specified equivalence factor) per litre. Use now not recommended.

normalize or (*esp. Brit.*) **normalise** **1** (*for a relational database*) to organize data into tables in such a way as to minimize duplication and hence increase efficiency. **2** (*for a probability distribution*) to divide all probabilities by a constant factor so that their sum over all possible alternatives is 1. **3** (*for microarray data*) to adjust the measured intensities to correct for experimental bias. **4** (*for a cDNA library*) to generate a library such that all the genes in the library are represented at the same frequency. —**normalized** *adj.*; —**normalization** *n.*

normalized library *see normalize.*

normal range (*in clinical chemistry*) the range of values of a particular characteristic within which 95 percent of observations made on presumed normal healthy individuals fall. It is useful as a reference in the investigation of disease.

normal saline *an alternative and less suitable name for physiological saline.*

normal solution a solution in which the amount-of-substance concentration of the **equivalent** (def. 3) of the reagent is one mole per litre; the equivalence factor of the reagent should be specified. Not now recommended. *See also* normal (def. 2).

normal temperature and pressure *abbr.:* NTP or N.T.P. or ntp; *a former term for standard temperature and pressure.*

normetadrenaline *an alternative name for normetanephrine.*

normetanephrine or **normetadrenaline** 3-*O*-methylnorepinephrine; an inactive metabolite of norepinephrine produced by the action of **catechol *O*-methyltransferase**.

normo+ or (*before a vowel*) **norm+** *comb. form* denoting normal; used especially in biology and medicine to indicate within the normal range. *See also* eu+.

normoblast a normal precursor cell to an erythrocyte, characterized by condensation of the nucleus into a homogeneous densely staining body. Normoblasts are normally found only in hemopoietic tissue. —**normoblastic** *adj.*

normocyte an erythrocyte of normal colour, shape, and size. —**normocytic** *adj.*

normoglycemia or (*esp. Brit.*) **normoglycaemia** *an alternative term for euglycemia.* —**normoglycemic** or (*esp. Brit.*) **normoglycaemic** *adj.*

normotensive having an arterial blood pressure within the normal range for the particular group to which the subject belongs.

Norrie disease *see Norrin.*

Norrin the protein (133 amino acids) encoded by the gene associated with the X-chromosome-linked Norrie disease. The human protein is highly expressed in retina, cerebellum, and olfactory epithelia, and shares 94% sequence identity with the mouse homologue. The secreted portion (residues 25–133) contains a cysteine-rich C-terminal domain. Numerous mutations result in congenital blindness, frequently associated with mental retardation and deafness, and occasionally with hypogonadism and microcephaly.

norsteroid any steroid that, relative to a parent compound, lacks either one axial methyl group or one methylene group in a side chain, or that has one ring contracted by one carbon atom. *See also* nor+.

Northern blotting or **Northern transfer** any **blotting** in which the primary electrophoresis is performed with RNA, which is subsequently hybridized to radioactive DNA. The term was coined to distinguish the process from **Southern blotting**, which is performed with DNA.

norvaline *symbol:* Avl (from aminovaleric) or Ape (from aminopenantoic) or (*formerly*) Nva; 2-aminovaleric acid (now the preferred trivial name); 2-aminopentanoic acid; a non-protein α -amino acid. *See also* nor+ (def. 3).

NOS *abbr.* for **nitric-oxide synthase**.

nos+ or (*before a vowel*) **nos+** *comb. form* indicating disease.

nosocomial 1 associated with a hospital. **2** a disorder (e.g. an infection) acquired during a hospital stay that is unrelated to the primary condition of the patient. A nosocomial infection can refer to hospital workers as well.

nosogenesis *an alternative term for pathogenesis*. —**nosogenic** or **nosogenetic** *adj.*

nosography a written systematic classification and description of diseases.

nosology the branch of medicine dealing with the classification of diseases.

notatin *a name sometimes still used for glucose oxidase*. Notatin was so called because it is produced in considerable quantity by some microfungi, e.g. *Penicillium notatum*.

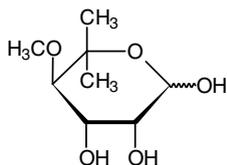

notch a gene, found in *Drosophila*, that encodes a protein essential for the proper differentiation of ectoderm. Expression of the *notch* gene is under the control of neurogenic genes. The gene product is a transmembrane protein (2703 amino acids) with 36 EGF-like repeats.

notexin a phospholipase A₂ (EC 3.1.1.4) from snake venom that acts as a presynaptic neurotoxin. The reaction is Ca²⁺-dependent.

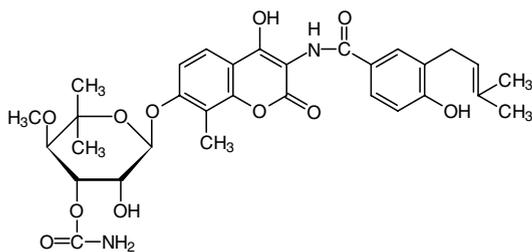

NotI a type 2 **restriction endonuclease**; recognition sequence: GC↑GGCCGC.

novel chemical entity *abbr.*: NCE; a molecule with a novel structure that is newly identified as a potential drug (and hence has not been described before in the literature).

noviose 6-deoxy-5-*C*-methyl-*L*-lyxo-hexose 4-methyl ether; a carbohydrate component of **novobiocin**.

novobiocin an antibiotic produced by *Streptomyces spheroides*, *S. niveus*, and certain other species; it is active against Gram-positive and some Gram-negative bacteria. In susceptible organisms it is a specific inhibitor of (**DNA**) **gyrase**, interacting with the B subunit, and thereby interfering with DNA synthesis.

noxa (*pl.* **noxae**) anything that is harmful to living organisms. —**noxious** *adj.*

Np *symbol* for neptunium.

NP *abbr.* for **1** **neuropilin**. **2** **nitroprolin**.

NP-40 polyethyleneglycol-*p*-isooctylphenyl ether; a polyoxyethylene nonionic detergent, CMC 0.05–0.3 mm. *Proprietary name*: Nonidet P40.

NPAS2 *abbr.* for neuronal PAS domain protein 2; a basic helix-loop-helix transcription factor that has two **PAS domains**, each of which contains a heme group. It forms a dimer with **BMAL1** through which it binds to a specific DNA motif and directs transcription of over a hundred genes, including those for **period** and cryptochrome proteins. NPAS2 is homologous with **clock** and like it controls circadian activity and is regulated by the redox state of NAD(P). It has

the same role in the forebrain as clock has in the hypothalamus. CO binds the heme of NPAS2 and prevents it from dimerizing with BMAL1.

NPC *abbr.* for neural precursor cell (*see* **Nedd**).

NPN *abbr.* for nonprotein nitrogen.

NPY *abbr.* for neuropeptide Y.

Nramp1 *abbr.* for natural resistance-associated protein 1; a transmembrane protein characteristic of macrophages and associated with natural resistance to intracellular parasites (e.g. *Leishmania*, some mycobacteria) in mice. The human homologue is **NRAMP1**, in which structural variation is associated with susceptibility to pulmonary tuberculosis and possibly leprosy. NRAMP1 is homologous with **NRAMP2**, a proton-coupled divalent-metal transporter for Fe²⁺ in the brush border of the proximal small intestine. Mutations in Nramp2 cause microcytic anemia in mice and the Belgrade rat (which is anemic). Mutation in human NRAMP2 causes hemochromatosis in a subset of such patients.

nrdb *abbr.* for nonredundant database; *see* **composite database**.

N repeat *an alternative name for asparagine repeat*.

nrRNA *abbr.* for nuclear RNA.

NR protein *abbr.* for nitrogen regulatory protein.

NRPS *abbr.* for nonribosomal peptide synthesis.

NRSF *abbr.* for neuronal restricted silencing factor. *See* **REST**.

NRTI *abbr.* for nucleoside reverse transcriptase inhibitor.

NruI a type 2 **restriction endonuclease**; recognition sequence: TCG↑CGA.

ns *symbol* for nanosecond (i.e. 10⁻⁹ s).

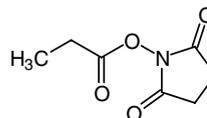

NSF *abbr.* for National Science Foundation (of the USA).

NSF protein *abbr.* for *N*-ethylmaleimide-sensitive fusion protein.

NSILA *abbr.* for nonsuppressible insulin-like activity.

NS-1 myeloma cells a cell line used for the production of monoclonal antibodies by fusion with splenocytes. NS-1 cells are deficient in the gene for **HGPRT** (HPRT) and are killed in the presence of aminopterin. In hybridomas the lack of HGPRT in NS-1 cells is genetically complemented by the gene from mouse splenocytes, and as a consequence they survive selection in culture medium containing **HAT**.

NSP *abbr.* for *N*-succinimidyl propionate, a propionylating agent.

NST *abbr.* for nonshivering thermogenesis.

NT *abbr.* for neurotrophin.

N terminus or *sometimes* **N terminal** the end of any peptide chain in any (poly)peptide or protein at which the 2-amino function of a constituent α -amino acid (or the 2-imino function of an α -imino carboxylic acid) is not attached in peptide linkage to another amino-acid residue. This function may bear an acyl group or other function in non-peptide linkage; when it is a free amino group (and also protonated and positively charged at neutral or acidic pH values), the chain end may then be alternatively termed the **amino terminus** (or NH₂ terminus) or **amino terminal** (or NH₂ terminal). However, 'amino terminus' is often used loosely for any N terminus. *Compare* **C terminus**. —**N-terminal** *adj.*

NTP 1 *abbr.* for any (unknown or unspecified) nucleoside (5')-triphosphate. **2** (*in clinical biochemistry*) *abbr.* for 5'-nucleotidase (EC 3.1.3.5). **3** or N.T.P. or ntp; *abbr.* for normal temperature and pressure; stp (i.e. standard temperature and pressure) now used.

NTPase *abbr.* for nucleoside triphosphatase.

NTP polymerase *see* **polynucleotide adenyllyltransferase**.

nu *symbol*: ν (lower case) or N (upper case); the thirteenth letter of the Greek alphabet. For uses *see* **Appendix A**.

nu body or **ν body** or **deoxyribosome** a type of spheroid particle seen on electron-microscopic examination of chromatin; now thought to be the same as a **nucleosome**.

Nuc *symbol* for an undetermined, unidentified, or unspecified nucleoside residue; alternative to N.

nucleo+ a variant for of **nucleo+** (before a vowel).

nuclear 1 of, pertaining to, or contained within the nucleus of a cell. **2** of, pertaining to, or concerning an atomic nucleus. **3** of, pertaining to, or operated by energy derived from fission or fusion of atomic nuclei.

nuclear area an alternative name for **nucleoid** (def. 2).

nuclear assembly protein 1 see **NAP1**.

nuclear atom or **central atom** (of a coordination entity) the atom to which all other atoms are directly attached.

nuclear body (*abbr.*: NB) or **PML nuclear body** or **PML oncogenic domain** a spatial domain or subcompartment in the mammalian nucleus that contains **PML** bound to several other proteins. It becomes disrupted in acute promyelocytic leukemia, associated with formation of the **PML-RAR α** fusion protein, and by some viruses, neoplasia, and inflammation. There is some evidence that nuclear bodies are sites for protein degradation.

nuclear division or **nuclear fission** the division of the nucleus of a cell, especially by **mitosis** or **meiosis**.

nuclear emulsion a fine-grained photographic emulsion designed for recording the tracks of subatomic particles within it.

nuclear envelope or **nuclear membrane** the membrane that surrounds the nucleus of a eukaryotic cell. It is a double membrane composed of two lipid bilayers separated by a gap of width 20–40 nm (the perinuclear space). The outer nuclear membrane is continuous with the endoplasmic reticulum of the cell and is sometimes studded with ribosomes. At specialized regions (**nuclear pores**) the outer nuclear membrane is connected to the inner nuclear membrane.

nuclear filament-related protein *abbr.*: NUF1; an essential component of the nucleoskeleton, with a role in cross-linking filaments or anchoring other molecules.

nuclear fission 1 (*in biology*) an alternative term for **nuclear division**. **2** (*in physics*) see **fission** (def. 1).

nuclear fraction an operational term for the material deposited by low-speed centrifugation of a homogenate of eukaryotic cells or tissue. It consists predominantly of nuclei together with unbroken cells.

nuclear fusion 1 (*in biology*) the **fusion** (def. 3) of the nuclei of a heterokaryon leading to the formation of a hybrid cell. **2** (*in physics*) see **fusion** (def. 4).

nuclear g-factor symbol g_N or nuclear g-value, a parameter that defines the energy of interaction of a nuclear spin with an applied magnetic field.

nuclear g-value alternative term for nuclear g-factor. Compare **G-value**.

nuclear isomer (*in physics*) see **isomer** (def. 2).

nuclear lamina the electron-dense layer lying on the nucleoplasmic side of the inner membrane of a cell nucleus. The polypeptides of the lamina are thought to be concerned in the dissolution of the nuclear envelope and its re-formation during mitosis.

nuclear localization signal *abbr.*: NLS; a sequence of amino acids seven to nine residues long within a protein, normally at sites away from the N or C terminus, that acts as a signal for the localization of the protein within the nucleus. Characteristically, NLSs are rich in basic residues, but include also one or more prolines.

nuclear magnetic resonance *abbr.*: NMR or nmr; the phenomenon that occurs when atomic nuclei that possess a magnetic moment are placed in a constant magnetic field of high intensity and are simultaneously exposed to electromagnetic radiation of an appropriate frequency in the radiofrequency region, whereby the nuclei are caused to change from a low-energy to a high-energy state with the absorption of energy. Nuclei that display this phenomenon include those of the nuclides protium, tritium, carbon-13, nitrogen-15, fluorine-19, and phosphorus-31; all these nuclei have nonzero spins and, therefore, magnetic moments. See also **nuclear magnetic resonance spectroscopy**.

nuclear magnetic resonance spectroscopy *abbr.*: NMR spectroscopy or nmr spectroscopy; absorption spectroscopy in the radiofrequency region based on the phenomenon of **nuclear magnetic resonance**. Unless otherwise qualified the term usually denotes nuclear magnetic resonance spectroscopy of protium atoms, also known as proton magnetic resonance spectroscopy (*abbr.*: pmr

spectroscopy). Nuclei of the same nuclide in different chemical environments give rise to distinguishable spectral lines, the positions, intensities, widths, and multiplicities of which give considerable information about the structure of complicated molecules containing such nuclei. The technique is also useful for determination of the concentrations of particular substances in complex environments, including that of an intact mammal. Compare **electron spin resonance spectroscopy**, **magnetic resonance imaging**.

nuclear magneton symbol: μ_N ; a quantity of magnetic moment, given by $\mu_N = eh/4\pi m_p = (m_e/m_p)\mu_B$, where e is the elementary charge, h is the Planck constant, m_e and m_p are the rest masses of an electron and a proton respectively, and μ_B is the **Bohr magneton**. It is a fundamental physical constant, of value $5.050\ 786\ 6(17) \times 10^{-27}$ J T⁻¹.

nuclear matrix see **matrix**.

nuclear matrix or **nuclear scaffold** the insoluble protein material left in the nucleus after a series of extraction procedures.

nuclear medicine the branch of medicine concerned with the use of radioactive nuclides for diagnosis or treatment of disease, or for medical research.

nuclear membrane an alternative name for **nuclear envelope**.

nuclear mitotic apparatus protein *abbr.*: NuMA; one of a family of abundant coiled-coil nuclear proteins located in the nucleus during interphase, but rapidly redistributes to the developing spindle poles when the nuclear envelope disassembles in prometaphase.

nuclear Overhauser effect or **nuclear Overhauser enhancement** *abbr.*: NOE; in nuclear magnetic resonance spectroscopy, a phenomenon in which saturation of the resonance of a nucleus or electron by the simultaneous application of a radiofrequency field causes, under appropriate conditions, a considerable increase in the polarization of the interacting nuclei and hence in the NMR signal produced.

nuclear Overhauser effect spectroscopy *abbr.*: NOESY; in nuclear magnetic resonance spectroscopy advantage can be taken of the fact that the energy states of the spins of two nuclei subject to the **nuclear Overhauser effect** (NOE) are slightly perturbed by the mutual dipolar coupling (the effects of J-coupling are ignored). A perturbation of the populations of the states of one of the spins will lead to a transfer of the populations between the upper and lower energy states of the second spin, thereby modifying the resonance intensity. The NOE can be either positive or negative depending on the nuclei involved and the rapidity of the relative motions of the two spins. The strength of the dipolar coupling is distance dependent. Thus measurements of the NOE between two nuclei can lead to the estimation of the distance between them. Conversely, if the distance between the two nuclei is fixed (e.g. in a bond), then the NOE measurement can yield an indication of the dynamic motions in the molecule. Two-dimensional spectroscopy, known as 2D NOESY, is used to elucidate dipolar coupling networks present in complex biomolecules, using the NOEs between individual ¹H nuclei in the molecule. The network of NOEs obtained provides a basis for the determination of the three-dimensional structure in solution. Applications include the structures of small proteins and nucleic acids as well as protein–drug and protein–nucleic acid complexes.

nuclear pore any opening in the **nuclear envelope** of a eukaryotic cell, where the inner and outer nuclear membranes are joined. The nuclear pores are the central feature of a complex in higher eukaryotes and are estimated to contain about 100 different polypeptides. The complex constitutes a diffusion channel about 9 nm in diameter through which proteins enter the nucleus and ribonucleoproteins leave. Small proteins enter freely but the entry of larger proteins is controlled by their containing one or more clusters of basic amino acids which comprise the nuclear localization sequence (*abbr.*: NLS). This involves binding to the nuclear envelope, followed by energy-dependent transit through the complex. Four soluble proteins have been shown to assist in the process: karyopherin α , other name: importin α (the NLS receptor), karyopherin β , other name: importin β (which mediates binding to the nuclear pore complex), a small guanosine triphosphatase (*abbr.*: GTPase), Ran, and p10/NTF2 (a protein that may coordinate the Ran-dependent association and disassociation reaction). Ran cycles between a GDP- and GTP-bound form, which might account for the consumption of

energy for the protein import. The exchange factor for Ran (RCC1) is located inside the nucleus whereas its GTPase-activating protein (Rab-GAP1 or RAN1) is cytoplasmic. Much less is known about the mechanism whereby the export of ribonucleoprotein is controlled. RNA itself does not seem to leave the nucleus.

nuclear quadrupole moment a parameter, given the symbol eQ , describing the effective shape of the ellipsoid of electric charge distribution of an atomic nucleus with spin greater than $1/2$. The nuclear electric quadrupole interacts with the electric field gradient eq at the nucleus, and its influence is observed in NMR, ENDOR, and Mössbauer spectroscopy.

nuclear receptor any intracellular protein that is specific for a ligand and elicits a response by binding to nuclear DNA without mediation of a second messenger. Some 48 are encoded in the human genome. They all contain a poorly conserved ligand-independent activation domain, a highly conserved DNA-binding domain that contains two zinc finger motifs, and a ligand-specific activation domain. They fall into three classes: (1) classic endocrine receptors (with high affinity for glucocorticoid, mineralocorticoid, steroid sex hormones, or thyroid hormones, and for 1,25-dihydroxy vitamin D); (2) adopted orphan receptors (e.g. those for retinoic acid and bile acids); and (3) orphan receptors that have no known physiological ligand.

nuclear remodelling factor see **NURF**.

nuclear rest see **nucleoid** (def. 4).

nuclear run-on or **nuclear run-off** a method in which nuclei isolated from cells are allowed to complete transcription of genes in the presence of radioactively labelled ribonucleotide triphosphates. Specific transcripts can be detected, and quantified, by hybridization with immobilized cDNA probes by dot blotting.

nuclear transformation transformation of a nuclide; the change of one nuclide into another.

nuclease any enzyme within subclass EC3.1, that catalyses the hydrolysis of ester linkages in nucleic acids. Nucleases with sugar specificity are referred to as ribonucleases or deoxyribonucleases; **endonucleases** create internal breaks, while 5'- and 3'-**exonucleases** remove nucleotide residues from the indicated end. Some nucleases are specific for double- or single-stranded nucleic acids.

nucleate **1** or **nucleated** possessing a nucleus. **2** to form, to act as, or to provide with, a nucleus or nuclei. **3** any salt of a nucleic acid.

nucleation **1** the act or process of nucleating or forming a nucleus. **2** (*in chemistry*) **a** the aggregation of molecules to form a polymer or a new phase within a medium. **b** (*also known as seeding*) the addition of a small quantity of finely divided crystalline material to a supersaturated solution in order to promote crystallization.

nuclei the plural of **nucleus**.

nucleic acid *abbr.*: NA; any single- or double-stranded polynucleotide of molar mass in the range 20 kDa to 40 GDa or more. Nucleic acids are either **deoxyribonucleic acids** (DNA) or **ribonucleic acids** (RNA). The phosphoric residue linking any constituent mononucleotide residue to the next bears one free hydroxyl group, which is weakly acidic. They are universal constituents of living matter and are concerned with the storage, transmission, and transfer of genetic information.

nucleics *an informal collective term sometimes used for* nucleotides, nucleosides, and nucleobases, whether constituents of nucleic acids or compounds of low M_r , and including their metabolic relatives and synthetic analogues.

nuclein the name given by J. F. Miescher (1844–95) to an unusual phosphorus-containing material that he isolated from the nuclei of pus cells, now known to have been **nucleoprotein**.

nucleinase a name once proposed to designate the enzymes now known as **nucleases**.

nucleo+ or (*before a vowel*) **nucle+** *comb. form* denoting **1** nucleus or nuclear. **2** nucleic acid.

nucleobase any nitrogenous base that is a constituent of a nucleoside, nucleotide, or nucleic acid.

nucleobindin a DNA-binding protein containing a signal peptide, leucine zipper, and basic amino-acid-rich regions. It was derived from a cell line from the lupus erythematosus-prone mouse MRL/T.

nucleocapsid the structure within a virus that comprises the pro-

teinaceous capsid and the genomic nucleic acid. In enveloped viruses the nucleocapsid is surrounded by an envelope.

nucleocidin 4'-C-fluoroadenosine 5'-sulfamate; an analogue of adenylate produced by *Streptomyces calvus*, and the first naturally occurring derivative of a fluorosugar to be described. It has anti-biotic activity against trypanosomes and inhibits translation in both eukaryotic and prokaryotic systems.

nucleocytoplasmic (of a structure or process) occurring between the nucleus and the cytoplasm; (of a property) relating the nucleus to the cytoplasm.

nucleodisome a structure consisting of two **nucleosomes** and isolable under certain conditions from some forms of chromatin.

nucleohistone any nucleoprotein consisting of DNA and histone(s).

nucleoid **1** resembling a nucleus. **2** the part or parts of a prokaryotic cell containing the genome and functionally equivalent to the nucleus of a eukaryotic cell. The meaning is sometimes extended to include the electron-dense inner zone observable in certain viruses. *Other names*: bacterial nucleus; chromatinic body; karyoid; nuclear area; nuclear body; nucleoid body; prokaryon. **3** the nucleus-like structure liberated from a eukaryotic cell by mild lysis. It contains histone-free supercoiled DNA within a flexible cage of RNA and protein. **4** or **nuclear rest** the nuclear residue sometimes observable in an erythrocyte. **5** the very dense core of a **microbody**.

nucleolar DNA or **ribosomal DNA** the DNA comprising the **nucleolar organizer(s)**.

nucleolar organizer or **nucleolus organizer** the portion of the genome of a eukaryotic cell that is associated with the **nucleolus** and contains the genes from which 45S ribosomal-precursor RNA is transcribed.

nucleolar phosphoprotein B23 or **nucleophosmin** or **numatrin** a monomeric, or, under some conditions, disulfide-linked dimeric, nucleolar protein that binds to single-stranded nucleic acids, and may be bound to rRNA in the nucleolus.

nucleolin or **protein C23** the major nucleolar protein of growing eukaryotic cells believed to function in pre-rRNA processing and ribosome assembly. It is a phosphoprotein found associated with intranucleolar chromatin and peri-ribosomal particles.

nucleolus (*pl.* **nucleoli**) a small, dense body one or more of which are present in the nucleus of eukaryotic cells. It is rich in RNA and protein, is not bounded by a limiting membrane, and is not seen during mitosis. Its prime function is the transcription of the nucleolar DNA into 45S ribosomal-precursor RNA, the processing of this RNA into 5.8S, 18S, and 28S components of ribosomal RNA, and the association of these components with 5S RNA and proteins synthesized outside the nucleolus. This association results in the formation of ribonucleoprotein precursors; these pass into the cytoplasm and mature into the 40S and 60S subunits of the ribosome. —**nucleolar adj.**

nucleolytic capable of causing hydrolysis of nucleic acid.

nucleon a neutron or a proton.

nucleonics the branch of physics concerned with the practical applications of nuclear phenomena.

nucleon number or **mass number** *symbol*: A ; a dimensionless physical quantity, having an integral value for any given nuclide, equal to the total number of nucleons (i.e. protons and neutrons) contained in the nucleus of an atom of the nuclide; it also is the integer nearest to the numerical value of the relative atomic mass of that nuclide and is equal to the arithmetical sum of the **neutron number**, N , of the nuclide and the **proton number**, Z , of the relevant chemical element: i.e. $A = N + Z$. The nucleon number may be attached to the symbol for the chemical element as a left superscript, or to the name of the element as a suffix; e.g. ^{14}C , or carbon-14.

nucleophile or **nucleophilic reagent** any reagent that is preferentially attracted to a region of low electron density in a chemical reaction.

Compare **electrophile**.

nucleophilic **1** of, pertaining to, or being a **nucleophile**; having or involving an affinity for regions of low electron density in a chemical reactant. **2** describing a chemical reaction in which a nucleophilic reagent participates.

nucleophilic catalysis catalysis by a **Lewis base**, which donates an electron pair to the reactant.

nucleophilic displacement *an alternative term for nucleophilic substitution reaction.*

nucleophilicity the relative reactivity of a nucleophile, measured in terms of the relative rate constants of different nucleophiles towards a common reactant.

nucleophilic reagent *an alternative term for nucleophile.*

nucleophilic substitution reaction or **nucleophilic displacement** a chemical reaction in which a **nucleophile** effects heterolytic substitution in another reactant, both bonding electrons being supplied by the nucleophile.

nucleophosmin *see nucleolar phosphoprotein B23.*

nucleoplasm all the protoplasm contained within the nuclear envelope of a living cell. —**nucleoplasmic** *adj.*

nucleoplasmin a heat-stable acidic protein present in the nucleoplasm of many cell types. It forms complexes with histones, and functions in the assembly of nucleosomes in the formation of chromatin.

nucleoporin any protein that is a component of the nuclear pore complex. *See nuclear pore.*

nucleoprotamine any nucleoprotein consisting of DNA and protamine(s).

nucleoprotein any complex of a protein with a deoxyribonucleic acid (**deoxyribonucleoprotein**) or a ribonucleic acid (**ribonucleoprotein**).

nucleosidase any enzyme that hydrolyses the *N*-glycosidic bond in a **nucleoside** (or in a nucleotide or some other derivative of a nucleoside). Such enzymes are classified within the sub-subclass EC 3.2.2, i.e. enzymes that hydrolyse *N*-glycosyl compounds.

nucleoside 1 *symbol* (for a residue of an undetermined, unknown, or unspecified nucleoside): N or Nuc; any **glycosylamine** that is a component of a nucleic acid and that consists of a nitrogenous base linked either to β -D-ribofuranose (forming a ribonucleoside, as in RNA) or to 2-deoxy- β -D-ribofuranose (forming a deoxyribonucleoside, as in DNA). The base is either a purine (linked at N-9) or a pyrimidine (linked at N-1, or in the case of pseudouridine at C-5). **2** any compound that is a glycosylated heterocyclic nitrogenous base; the glycoside moiety commonly is ribose, but is sometimes a different sugar or a modified sugar; e.g. cytarabine (1- β -D-arabinofuranosyl-cytosine).

nucleoside antibiotic any of a group of **nucleosides** (def. 2) that are not components of nucleic acids but are produced by various microorganisms and fungi (especially *Streptomyces* spp.), and have antibiotic activity. They contain unusual nitrogenous bases and/or unusual sugars (or sugar derivatives), and may also contain one or more additional components. Examples include **cordycepin**, **nucleocidin**, **puromycin**, and **showdomycin**.

nucleoside cyclic phosphate or **cyclic nucleotide** any nucleotide that consists of a nucleoside doubly esterified with one [ortho]phosphate molecule on its glycoside moiety (usually at the 3' and 5' positions, but sometimes at the 2'- and 3'-positions) e.g. cyclic AMP.

nucleoside diphosphatase EC 3.6.1.6; *systematic name*: nucleoside diphosphatase phosphohydrolase; an unspecific enzyme that hydrolyses a number of nucleoside diphosphates to a nucleoside monophosphate and orthophosphate. Substrates include IDP, GDP, UDP, and D-ribose 5-phosphate. There is also the more specific **guanosine-diphosphatase**, EC 3.6.1.42; *systematic name*: GDP phosphohydrolase, which hydrolyses guanosine diphosphate to guanylic acid and orthophosphate.

nucleoside diphosphate any nucleotide that consists of a nucleoside esterified with diphosphate on its glycoside moiety (usually at the 5' position, when the symbol is NDP).

nucleoside diphosphate reductase EC 1.17.4.1; *recommended name*: ribonucleoside-diphosphate reductase; *systematic name*: 2'-deoxyribonucleoside-diphosphate:oxidized thioredoxin 2'-oxidoreductase; *other name*: ribonucleotide reductase. A nucleotide reductase enzyme, present in most organisms, that catalyses the formation of a 2'-deoxyribonucleoside diphosphate, oxidized thioredoxin, and H₂O from a ribonucleoside diphosphate and reduced thioredoxin. It requires iron and ATP. The enzyme from *Escherichia coli* is formed from B2 protein (dimer of β chains; Fe-binding subunit, 3-D structure known) and B1 (dimer of α chains), which contains a disulfide/sulfhydryl redox system; it is the enzyme responsible for the biosynthesis of deoxyribonucleotides from ri-

bonucleotides, e.g. in *de novo* biosynthesis. The B2 dimer contains two Fe(III) ions (one on each monomer) that form a Fe³⁺-O-Fe³⁺ group. This forms a free radical centre (involving an enzyme tyrosyl residue) that abstracts a hydrogen from the ribose (ultimately from the 2' position, but the mechanism is complex). This leads to loss of the 2'-OH. Hydride ions are lost from enzyme sulfhydryl groups to react with these OH• groups to form water, resulting in formation of disulfide groups. The hydrogen abstracted by the free radical centre is returned to what now becomes 2'-deoxyribose. The enzyme's disulfide groups are reduced in turn by thioredoxin. There is an allosteric site on the B1 subunit dimer; ATP acts at this site as an activator and dATP as an inhibitor, in a complex interaction with a second site that determines the specificity of the enzyme towards different nucleotides. A **nucleoside triphosphate reductase** is produced when the organisms are growing anaerobically.

nucleosidediphosphosugar or **nucleoside diphosphate sugar** or **nucleotide sugar** any **nucleotide** (def. 2) in which the distal phosphoric residue of a nucleoside 5'-diphosphate is in glycosidic linkage with a monosaccharide (or a derivative of a monosaccharide).

nucleoside monophosphate *see nucleoside phosphate.*

nucleoside phosphate or **nucleoside monophosphate** any nucleotide that consists of a nucleoside esterified with [ortho]phosphate on its glycoside moiety (usually at the 5'-position, when the symbol is NMP).

nucleoside reverse transcriptase inhibitor *abbr.*: NRTI; a modified natural nucleoside used as an antiretroviral drug in AIDS therapy. It suppresses retrovirus replication by interfering with the viral reverse transcriptase, causing premature chain termination during DNA synthesis. It is often used in combination with other drugs. *Compare non-nucleoside reverse transcriptase inhibitor.*

nucleoside-triphosphatase *abbr.*: NTPase; EC 3.6.1.15; an unspecific diphosphate phosphohydrolase enzyme that catalyses the hydrolysis of the distal diphosphate bond in various nucleoside triphosphates, with formation of [ortho]phosphate and the corresponding nucleoside diphosphate. It acts also on certain other diphospho-compounds.

nucleoside triphosphate any nucleotide that consists of a nucleoside esterified with triphosphate on its glycoside moiety (usually at the 5'-position, when the symbol is NTP).

nucleoside triphosphate reductase EC 1.17.4.2; *recommended name*: ribonucleoside-triphosphate reductase; *systematic name*: 2'-deoxyribonucleoside-triphosphate:oxidized thioredoxin 2'-oxidoreductase. A nucleotide reductase enzyme found in *Lactobacillus leichmannii* (and presumably related organisms). It catalyses the formation of a 2'-deoxyribonucleoside triphosphate, oxidized thioredoxin, and H₂O from a ribonucleoside triphosphate and reduced thioredoxin. It requires cobalt and ATP.

nucleosomal remodelling and histone deacetylase *see NURD.*

nucleosome a particle that forms the primary packing unit of DNA in chromatin. Nucleosomes give electron micrographs of decondensed chromatin a 'beads-on-a-string' appearance, and are released on mild digestion of eukaryotic nuclei with micrococcal endonuclease. Each consists of a segment of duplex DNA, 160–240 base pairs long, with associated **histone**; about 146 base pairs of the DNA comprise a **core particle** and the remainder form the linker DNA. The core particle is a disklike structure, 11 nm in diameter and 5.7 nm thick, consisting of two molecules each of histones H2A, H2B, H3, and H4 with approximately two superhelical turns of double-stranded DNA wound round it. In the intact nucleosome, an average of one molecule of histone H1 is on the exterior of each core particle and appears to mediate the packing together of adjacent nucleosomes in condensed chromatin. *See also nu body.*

nucleosome code the hypothesis that the local concentration and combination of differentially modified core histones of nucleosomes determines the euchromatin or heterochromatin state of DNA. *See histone code.*

nucleosome remodelling factor *see NURF.*

nucleotidase any phosphoric monoester hydrolase enzyme that catalyses the hydrolysis of a **nucleotide** (def. 1, 2) to yield a nucleoside and orthophosphate. The principal ones are classified under three EC numbers (1) EC 3.1.3.31; *recommended name*: nucleotidase; enzymes having a wide specificity for 2', 3', and 5'-nu-

cleotides, and that also hydrolyse glycerol phosphate and 4-nitrophenyl phosphate; (2) EC 3.1.3.6; *recommended name*: 3'-nucleotidase; an enzyme having a wide specificity for 3'-ribonucleotides; these enzymes hydrolyse a 3'-ribonucleotide to a ribonucleoside and orthophosphate. Some such enzymes are not sugar specific. (3) EC 3.1.3.5; *recommended name*: 5'-nucleotidase; an enzyme having a wide specificity for 5'-ribonucleotides. These enzymes hydrolyse a 5'-ribonucleotide to a ribonucleoside and orthophosphate.

nucleotide 1 or **mononucleotide** or **nucleoside [mono]phosphate** any compound that consists of a **nucleoside** (def. 1) esterified with [ortho]phosphate at either the 3'- or the 5'-hydroxyl group of its glucose moiety (ribonucleosides giving **ribonucleotides**, and deoxyribonucleosides giving **deoxyribonucleotides**). Nucleotides are the constitutional units into which nucleic acids are broken down by partial hydrolysis and from which they are considered to be built up. **2** any compound consisting of a **nucleoside** (def. 2) that is esterified with [ortho]phosphate or an oligophosphate at any hydroxyl group on its glucose moiety. In this sense the term includes **nucleoside cyclic phosphate**, **nucleoside diphosphate**, **nucleoside diphosphosugar**, **nucleoside triphosphate**, and pyridine nucleotide. **3** any compound containing a moiety of a nucleotide (def. 1, 2). Included are: any carrying an additional phosphoric group at another position on the glucose moiety; any formed (actually or conceptually) from two or more such nucleotides, whether the same or not, joined together in phosphoric-ester linkage (to form an **oligonucleotide** or a **polynucleotide**); and, in certain instances, any formed from such a nucleotide joined through a phosphoric anhydride link either to a second nucleotide or to some other phosphate ester. Exceptionally, the term includes also certain analogous compounds (especially flavin mononucleotide, and hence also flavin-adenine dinucleotide) that, being derivatives of ribitol, are not true nucleoside phosphates or else are not formed exclusively from them.

nucleotide-binding fold or **nucleotide-binding pocket** a common structural feature of numerous dehydrogenase enzymes utilizing either of the nucleotide coenzymes NAD or NADP as the acceptor. The coenzyme fits in a pocket made by the folding of the polypeptide chain. Many such enzymes combine specifically with **blue agarose** owing to putative structural similarity of the bound dye (Reactive Blue 2) to the coenzyme, a property that can be exploited in the separation and purification of these enzymes by affinity chromatography. A similar property is shown by some other nucleotide-binding enzymes (and also by certain other proteins that do not bind nucleotides).

nucleotide coenzyme any **nucleotide** (def. 2, 3) that is either (1) a coenzyme (e.g. nicotinamide-adenine dinucleotide), or (2) a substrate-carrier in an anabolic reaction (e.g. uridine diphosphate glucose).

nucleotide excision repair *abbr.*: NER; the form of DNA repair in which ultraviolet light-induced photoproducts (e.g. pyrimidine dimers), chemical adducts (e.g. induced by carcinogens such as benzpyrene), or interstrand crosslinks are removed and the defect is repaired. This involves excision of an oligonucleotide that contains the lesion and filling of the resulting single-strand gap. In *E. coli*, the repair is effected by UvrABC excinuclease, the excised oligonucleotide being ≈ 12 nt long. In eukaryotes, some 16 gene products are required, and the excised oligonucleotide is 24–32 nt long. Defective NER is the cause of xeroderma pigmentosum and of Cockayne syndrome. *See also* **excision repair**.

nucleotide-gated channel *see* **ion channel**.

nucleotide reductase *see* **nucleoside diphosphate reductase**, **nucleoside triphosphate reductase**.

nucleotide sugar *an alternative name for* **nucleoside diphosphate sugar**.

nucleotide unit the repeating unit of a polynucleotide chain, defined typically by the sequence of atoms from the phosphorus atom at the 5' end of any one of its component glucose residues to the oxygen atom at the 3' end of the same residue and including all the atoms of the glucose residue and its attached phosphoric residue and nucleobase; atypically, the nucleotide unit at the 5' end of a chain may lack a phosphate group. Nucleotide units in a given chain are numbered sequentially from the chain's 5' end irrespective

of the presence or absence of a phosphate group on the 5'-terminal unit.

nucleotidyl the acyl group formed from a nucleoside [mono]phosphate by removal of a hydroxyl group from its phosphoric group.

nucleotidyltransferase an enzyme of subclass EC 2.7.7; such enzymes transfer a nucleotidyl group to a reactant. Possession of such activity is a common mechanism of drug resistance (especially to **aminoglycoside antibiotics**) in bacteria. An example is gentamicin 2''-nucleotidyltransferase (EC 2.7.7.46); *systematic name*: NTP:gentamicin 2''-nucleotidyltransferase; *other name*: 2''-aminoglycoside nucleotidyltransferase. It catalyses a reaction between NTP and gentamicin to form pyrophosphate and 2''-nucleotidylgentamicin. This enzyme can be isolated from *Escherichia coli* and *Klebsiella pneumoniae* plasmids, and confers resistance to kanamycin, gentamicin, dibekacin, sisomicin, neomycin, and tobramycin by adenylating the 2''-OH group of these antibiotics.

nucleus (*pl. nuclei*) **1** (*in biology*) the most conspicuous organelle of a eukaryotic cell; it contains the chromosomes and (except for mitochondria and chloroplasts) is the sole site of DNA replication and of RNA synthesis in the cell. Usually a spheroidal body, it is separated from the cytoplasm by the nuclear envelope. **2** (*in physics*) **atomic nucleus** the positively charged central part of an atom, with which is associated almost the whole of the mass of the atom but only a very small part of its volume. It is composed of nucleons, i.e. protons and neutrons. **3** (*in organic chemistry*) a characteristic arrangement of atoms, especially a ring structure, that occurs in a series of related organic compounds; e.g. the benzene nucleus. **4** a particle on which a crystal, droplet, or bubble forms in a fluid.

nuclide any individual species of atom, whether stable, metastable, or unstable, that is characterized by the constitution of its nucleus and by its **nucleon number**, **proton number**, and nuclear energy state; its mean life must be long enough for the species to be observable. Nuclides having the same proton number but different nucleon numbers or different nuclear energy states are termed isotopic nuclides, or **isotopes**. Nuclides having the same nucleon number but different proton numbers are termed isobaric nuclides, or **isobars**. Nuclides having the same neutron number but different proton numbers are termed isotonic nuclides, or **isotones**. A given nuclide may be specified by attaching its nucleon number either to the name of the relevant chemical element as a suffix, or to the symbol for the chemical element as a left superscript; the proton number may be attached to the symbol as a left subscript; e.g. carbon-14, ^{14}C , or $^{14}_6\text{C}$. A metastable nuclide (i.e. one with an elevated nuclear energy state) may be differentiated from its counterpart with the same nucleon number by attaching the suffix m to the nucleon number; e.g. technetium-99m or $^{99\text{m}}\text{Tc}$. (Absence of a nucleon number attached to its name or symbol implies the presence of all isotopes of the element in natural abundance.) —**nuclidic** *adj.*

nude a mutant strain of mouse or rat that lacks a **thymus gland** and hence is devoid of **T lymphocytes** and is hairless. It is caused by a mutation in the *nude* gene, which encodes a transcription factor of the winged helix type. *See* **forkhead**.

NUF1 *abbr.* for nuclear filament-related protein.

Nujol *a proprietary name for* a high-boiling-point fraction of liquid paraffin widely used for making mulls for infrared spectroscopy. It is also used medicinally as a laxative, and was referred to by the poet e. e. cummings in *Poem, or Beauty hurts Mr. Vinal*: '...little liver pill-/hearted-Nujol-needing-There's-A-Reason...'

null a minimum or zero value, especially of an electric current.

null cell *an alternative term for* **null lymphocyte**.

nullisomic 1 describing a cell, organism, strain, etc. that lacks one or more pairs of homologous chromosomes. **2** such a cell, organism, strain, etc.

null lymphocyte or **null cell** a **lymphocyte** that is not recognizable as either a B lymphocyte or a T lymphocyte.

null method or **zero method** a method of measurement in which a zero reading in a sensitive, but not necessarily calibrated instrument, e.g. a galvanometer, enables an unknown value of some property to be deduced by comparison with reference values.

NuMA *abbr.* for **nuclear mitotic apparatus protein**.

numatrin *another name for* **nucleolar phosphoprotein B23**.

number 1 a concept or expression of quantity reckoned in ones or

units; a particular value of such a quantity (which may be integral or zero). **2** the symbol or group of symbols used to represent a number (def. 1); numeral; figure. **3** a numeral or string of numerals used for identification (of something, especially a member of a sequence). **4** to assign numbers to (members of a series); to label with a number or numbers.

number-average molar mass *see* average molar mass.

number-average relative molecular mass or (formerly) **number-average molecular weight** *see* average relative molecular mass.

number concentration *symbol: C; see* concentration (def. 1d).

number fraction *symbol: δ* ; the number of defined particles or elementary entities of a specified component of a system divided by the total number of defined particles in the system.

numerical aperture (*in optics*) *abbr.: NA*; the arithmetic product of the refractive index of the medium in which the objective (lens) of a microscope is situated and the sine of half the angle of view of the objective. The resolving power of the lens is proportional to its numerical aperture.

NURD *abbr. for* nucleosomal remodelling and histone deacetylase; a protein complex found in *Xenopus* and mammals and involved in nucleosome remodelling by some as yet unknown mechanism. It contains histone deacetylases (HDAC1 and HDAC2), retinoblastoma-associated proteins (RbAp48 and RbAp46), metastasis-associated proteins (MTA1 and MTA2), and a subunit (MBD3) that contains a methyl-CpG-binding domain. The largest component (Mi2) contains two chromodomains, a zinc finger, and a distinctive helicase/ATPase domain.

NURF *abbr. for* nucleosome remodelling factor; a tetrameric protein complex of *Drosophila* that acts with **GAGA factor** to disrupt nucleosome spacing near the promoter of the Hsp70 gene. One component of NURF is an ATPase protein called initiation switch (**ISWI**).

Nurr 1 an orphan nuclear receptor expressed almost exclusively in the central nervous system, where it is confined to dopaminergic neurons. In mice, it seems to be absolutely required for generation of these neurons.

nurse cell a cell that is connected by cytoplasmic bridges to an oocyte and thereby conveys macromolecules to the growing oocyte.

nus any of three *Escherichia coli* genes that are involved in transcriptional termination. The product NusA binds to RNA polymerase, RNA, **rho**, and the antitermination protein pN, the product of the *N* gene. It may also bind to NusB. It participates in both the termination and antitermination of transcription. NusB is involved in the transcription termination process at certain sites during normal bacterial growth and is essential for the function of pN. NusG is involved in transcription antitermination.

NutraSweet a proprietary name for aspartame.

nutrient 1 any chemical substance that can be used by an organism to sustain its metabolic activities. **2** serving as or conveying nourishment. **3** (*in microbiology*) describing a solid or liquid medium that is able to support the growth of a range of nutritionally undemanding chemoorganotrophs.

nutrition 1 the supply of substances (i.e. nutrients) required by an organism, directly or indirectly, for its metabolic activities, i.e. for the provision of energy, for growth, and/or for the renewal of degraded components. **2** the act or process of supplying or receiving nutrients. **3** the scientific study of the nutrient requirements of particular organisms and of the supply of those nutrients. —**nutritional** *adj.*

nutritional mutant a mutant strain of a microorganism (alga, bacterium, or fungus) that requires a supply of one or more growth factors in addition to those required by the wild type, i.e. a mutation in a **prototroph** to form an **autotroph**.

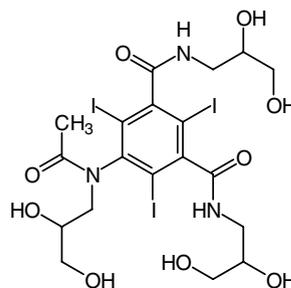

nutritive 1 containing nutrient(s). **2** of, concerned in, or promoting nutrition.

nux vomica the dried seeds of the Indian tree, *Strychnos nux-vomica*. They are a source of **strychnine**, **brucine**, and other poisonous alkaloids.

Nva *symbol for* the α -amino acid **norvaline** (now known as 2-aminovaleric acid, *symbol: Avl*).

Nycodenz the proprietary name for *N,N'*-bis(2,3-dihydroxypropyl)-

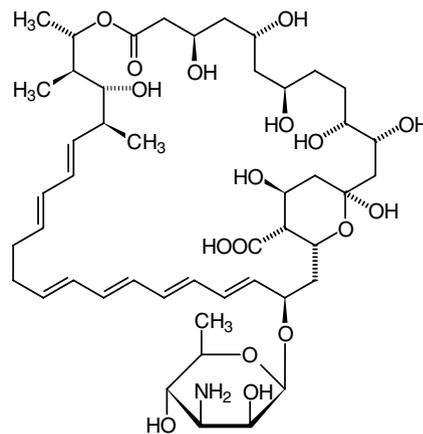

5-[*N*-(2,3-dihydroxypropyl)acetamido]-2,4,6-triiodoisophthalamide; a dense, synthetic, nonionic substance, highly soluble in water, that is capable of forming (autoclavable) aqueous solutions of densities up to 2.1 g mL⁻¹. It is one of several synthetic water-soluble triiodobenzene derivatives designed for use as intensifiers in radiology that have found use in isopycnic gradient fractionation of biological particles.

nyctalopia the medical term for night blindness.

nylon any of a class of synthetic thermoplastic substances, characterized chemically as long-chain polyamides and formed by condensation polymerization of dicarboxylic acids with diamines. They have high melting points, are insoluble, tough, resistant to fracture, and exhibit low friction. Hence they are useful in the manufacture of laboratory apparatus for which these properties are advantageous. Nylon can be formed into fibres or sheets and used for coatings, fabrics, and many other products. It is also used as an alternative to nitrocellulose in hybridization membranes.

nystatin a **mycosamine**-containing polyene antifungal antibiotic complex (three components) produced by *Streptomyces noursei* and other *Streptomyces* spp. It is very similar to **amphotericin B** in its properties and mechanism. Two proprietary names are Fungicidin and Mycostatin.

nystatin A₁

N-Z amines a proprietary enzymic hydrolysate of casein, used in bacterial growth media.

NZCYM a culture medium for the growth of *E. coli* and suitable for the propagation of bacteriophage lambda. It contains **N-Z amines**, casamino acids, yeast extract, MgSO₄, and NaCl.

NZM a culture medium for the growth of *E. coli* that contains **N-Z amines**, MgSO₄, and NaCl.

NZO mouse *abbr. for* New Zealand obese mouse.

NZY a culture medium for the growth of *E. coli* that contains **N-Z amines**, yeast extract, and NaCl.

Oo

o+ prefix (in peptide hormone nomenclature) denoting ovine.

o- prefix (in chemical nomenclature) denoting *ortho-*. Compare *m-*, *p-*.

O symbol for 1 oxygen. **2** a residue of the ribonucleoside orotidine (alternative to Ord).

O- prefix (in chemical nomenclature) indicating substitution on oxygen; a particular oxygen atom in a molecule may be specified by suffixing an appropriate superscript.

OA abbr. for ovalbumin.

OAA abbr. for oxaloacetic acid, or oxaloacetate.

OAADPr abbr. for 1-*O*-acetyl-ADP-ribose.

OAG abbr. for 1-oleoyl-2-acetyl-glycerol.

Oakley-Fulthorpe technique a simple double immunodiffusion method that can be used for quantitative determination of antigen concentrations; it is essentially a development of the **Oudin technique**. The antiserum in 1 agar is placed at the bottom of a cylindrical tube above which is placed a layer of 1 agar gel in 1 saline, and 0.5 *o*-cresol (as a preservative). Subsequently a bacterial filtrate (containing antigen) is layered onto the agar-saline gel and the tube then incubated at 37 °C. Disks or lines of flocculation of antigen-antibody complexes are produced in the agar-saline gel, from whose positions the concentration of antigen(s) may be determined. [After C. L. Oakley and A. J. Fulthorpe, who described the technique in 1953.]

O antigen 1 any of the lipopolysaccharide-protein somatic antigens of the cell walls of Gram-negative bacteria, especially those of the Enterobacteriaceae. They are useful in the serological classification of *Salmonella*, *Shigella*, and other bacteria. **2** (sometimes) an alternative name for H antigen (present on erythrocytes of blood group O); see **blood-group substance**.

OAT abbr. for ornithine- δ -aminotransferase; EC 2.6.1.13; an enzyme that uses pyridoxal phosphate as coenzyme to catalyse the reaction:

ornithine + 2-oxoglutarate = pyrroline-5-carboxylate + glutamate.

It is widespread in mammalian tissues and especially active in liver, kidney, and small intestinal mucosa. It is a homohexamer of the mitochondrial matrix. The crystal structure of the human enzyme (each subunit contains 439 amino acids) comprises a total of 12 alpha helices and 14 beta strands, with a central domain that contains 8 alpha helices and 7 beta strands. Numerous mutations lead to enzyme deficiency and gyrate atrophy of the choroid and retina with hyperornithinemia and hyperornithinuria.

+oate suffix (in chemical nomenclature) denoting the carboxylate group, -COO⁻.

ob see *ob/ob*.

obelin a luminescent protein obtained from the jellyfish, *Obelia geniculata*. It is similar to **aequorin** in properties and use.

obese having an excessive amount of body fat. Obesity is the second largest cause of preventable death in the developed world and a major risk factor for vascular disease, diabetes mellitus type 2, and some cancers. —**obesity** *n*.

obestatin a peptide encoded by the **ghrelin** gene that opposes ghrelin's effects on food intake. The 23-residue peptide, has the structure FNAPFDVGKLSGAQYQQHGRAL-amide in the rat. Treatment of rats with the peptide depresses food intake, inhibits jejunal contraction and results in decreased body weight gain. Ghrelin and obestatin are both derived from the ghrelin gene propeptide by posttranslational cleavage and modification. Obestatin binds to the orphan **G-protein-coupled receptor** GPR39.

OB fold abbr. for oligonucleotide/oligosaccharide binding fold; a protein sequence (\approx 110 residues) present in most prokaryotic and eukaryotic ssDNA-binding proteins. It does not have a definite sequence motif but forms a highly curved five-stranded beta sheet that closes in on itself to form a beta barrel. The BRCA2 protein contains three OB folds.

objective (in optics) the lens or system of lenses in an optical instrument (especially a compound microscope) that is positioned nearest to the object to be viewed.

object-oriented database abbr.: OODB; a database in which data are stored as abstract objects, with abstract relationships between them. The data representations are flexible (e.g. including character strings, digitized images, tables) and objects may be grouped together.

oblate 1 having an equatorial diameter longer than the polar diameter. **2** describing an **ellipsoid of rotation** (including a spheroid) generated by rotation of an ellipse about its minor axis. **3** describing any protein of **oblate** (def. 1) dimensions, as observed in hydrodynamic measurements. Compare **prolate**.

obligate by necessity, or without option; used especially of the nature of the environment or of the mode of life of an organism; e.g. obligate aerobe (see **aerobe**), obligate anaerobe (see **anaerobe**). Compare **facultative**.

obligate heterozygote an individual in a family who is proven to carry one copy of a recessive allele by having had affected progeny who inherited two copies of the mutant allele, one from each parent.

O blood-group substance see **ABO system**.

ob/ob the genotype symbol for any strain of mouse with an inherited form of severe obesity, due to a homozygous autosomal recessive mutation on chromosome 6. Such animals display marked hyperglycemia and insulin resistance. A protein named **leptin**, or OB protein, has been implicated in the control of fat mass and is a product of the *ob* mutant gene, being deficient in *ob/ob* mice.

obscurin a protein of the Z band of skeletal muscle that interacts with titin.

obtuse angle any plane angle greater than 0.5π rad or 90° and less than π rad or 180° .

Oc symbol for the octyl group.

ocatin a storage protein that constitutes over 60% of the soluble protein of oca tubers (*Oxalis tuberosa*). It is homologous with a group of pathogenesis-related proteins and has antibacterial and antifungal activity.

Occam's razor a variant spelling of **Ockham's razor**.

occlude 1 to block or obstruct (a passage, tube, opening, etc.). **2** (in chemistry) to take up and retain something in the interstices of a solid; e.g. to absorb a gas into a metal or to entrap liquid within crystals during their formation. —**occlusion** *n*.

occludin an integral membrane protein that localizes in tight junctions in chick liver; four putative transmembrane domains reside in the N-terminal half of the protein.

occult concealed or hidden; not apparent to the unaided eye.

occult blood blood that is present in a sample in such small quantities, e.g. in feces, that it can only be detected by chemical testing or by microscopy.

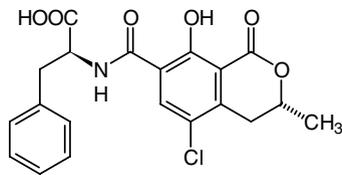

occult virus a virus whose presence in a host is inferred but whose isolation or detection cannot be achieved.

occupancy 1 the state or condition of being filled or occupied. **2** the number of similar sites occupied, usually expressed as a fraction or percentage of the total number available. It can refer, e.g., to the number of receptors on a cell surface occupied by a particular agonist or to the number of atomic orbitals of a particular subshell filled by electrons.

occupation theory of agonist action a theory stating that the magnitude of the response to an agonist is directly proportional to the fraction of specific receptors occupied by molecules of the agonist; it assumes that the binding of agonist to receptor is reversible. According to this theory the response will increase to a maximal value when all the receptors are occupied. Compare **rate theory of agonist action**.

ochratoxin any one of several **mycotoxins** produced by the fungus *Aspergillus ochraceus*, other *Aspergillus* spp., and *Penicillium* spp.; the major component, ochratoxin A, is a complex, chlorine-containing derivative of L-phenylalanine that inhibits phosphoenolpyruvate carboxykinase (EC 4.1.1.49) and may cause fatty

liver. These toxins may occur on contaminated foodstuffs such as corn (maize), peanuts, storage grains, etc.

ochratoxin A

ochre codon or **ochre triplet** *symbol*: UAA; one of the three terminator codons or **nonsense codons** found in messenger RNA.

ochre mutant any cell or virus carrying an **ochre mutation**.

ochre mutation a mutation that gives rise to an **ochre codon** at an abnormal position in a messenger RNA molecule.

ochre suppressor any of a number of mutations in *E. coli* resulting in changed anticodons of tRNAs that suppress an **ochre codon** (UAA) in mRNA. This allows insertion of one of several alternative amino acids into a polypeptide at that site. Examples are *supC* (Tyr) and *supG* (Lys). Some ochre suppressors (*supC* and *supG*) also suppress **amber codons**.

ochronosis the presence of brown-black pigment in the skin, cartilage, and other tissues due to **alcaptonuria**.

OCIF *abbr. for* osteogenic inhibitory factor. *See* **osteoprotegerin**.

Ockham's razor or **Occam's razor** a maxim stating that when explaining something there should be a minimal number of assumptions. *Entia non sunt multiplicanda praeter necessitatem* (entities should not be multiplied except from necessity). [After William of Ockham (1285–1349), English philosopher.]

Oco *symbol for* the octanoyl group.

OCS *the proprietary name for* a commercial xylene-fluor mixture suited to the liquid-scintillation counting of a wide range of toluene- and xylene-soluble organic samples, especially specimens solubilized in **NCS**.

oct+ *a variant form of* **octa+** (sometimes before a vowel).

OCT (*in clinical chemistry*) *abbr. for* ornithine carbamoyltransferase.

OCT a family of genes encoding transcription factors for eukaryotic RNA polymerase II promoters. The proteins contain a **POU domain** and contribute to the naming of that domain. They are leucine zipper proteins and bind to **octamer** sequences.

octa+ or **octo+** or (*sometimes before a vowel*) **oct+** *comb. form* denoting eight, eightfold, eight times.

octacos+ *comb. form* denoting twenty-eight, twenty-eightfold, twenty-eight times.

octacosanoate *see* **montanate**.

octacosanoyl *see* **montanoyl**.

octadeca+ *comb. form* denoting eighteen, eighteenfold, eighteen times.

octadecadienoic acid any straight-chain fatty acid having eighteen carbon atoms and two double bonds per molecule. Linoleic acid (*see* **linoleate**) is the *all-Z*-(9,12)-isomer and is a constituent of most vegetable oils and animal fats. The *all-E*-isomer of this acid is linolelaic acid, a constituent of the seeds of *Chilopsis linearis*, which also contain the *all-E*-(10,12)-isomer. A number of other isomers have been synthesized chemically.

octadecanoic acid *the systematic name for* stearic acid; *see* **stearate**.

octadecapentaenoic acid any straight-chain fatty acid having eighteen carbon atoms and five double bonds per molecule. The *all-Z*-(3,6,9,12,15)-isomer occurs naturally in dinoflagellates.

octadecatetraenoic acid any straight-chain fatty acid having eighteen carbon atoms and four double bonds per molecule. Several isomers occur naturally, including the *3E,9Z,12Z,15Z*-isomer, found in seed oil, and the *all-Z*-(6,9,12,15)-isomer, found in fish oil. The *9Z,11E,13E,15Z*-isomer and the *all-E*-(9,11,13,15)-isomer are α - and β -parinaric acid respectively, from *Parinarium laurinum*; both isomers are used as fluorescent probes.

octadecatrienoic acid any straight-chain fatty acid having eigh-

teen carbon atoms and three double bonds per molecule. A number of isomers occur naturally, the most prominent being the *all-Z*-(9,12,15)-isomer, (9,12,15)-linolenic acid; the *all-Z*-(6,9,12)-isomer is (6,9,12)-linolenic acid (*see* **linolenate**). *See also* **columbinic acid**, **eleostearate**.

octadecenoic acid any straight-chain fatty acid having eighteen carbon atoms and one double bond per molecule. (*Z*)-Octadec-9-enoic acid (i.e. oleic acid; *see* **oleate**) is the isomer found widely, often in high proportion, in plant and animal lipids, especially in olive oil. The *5E*- and *6Z*- (petroselenic acid; *see* **petroselenate**) isomers are found in seed oils; the *6E*- isomer is named **petroselaicid acid**, and the *9E*-isomer is elaidic acid, a common constituent of fats and oils (*see* **elaidate**). The *11E*- and *11Z*-isomers are, respectively, *trans*- and *cis*-vaccenic acid (*see* **vaccenate**).

octaethyleneglycol mono-*n*-decyl ether a nonionic C₁₀E₈ detergent (*see* C_xE_y).

octaethyleneglycol mono-*n*-dodecyl ether a nonionic C₁₂E₈ detergent (*see* C_xE_y).

octahedral coordination coordination in which six ligands are disposed about a central atom as if at the vertices of an octahedron enclosing that atom.

octahedron (*pl.* **octahedra**) any solid geometrical figure having eight plane triangular faces, 12 edges, and six tetrameric vertices. In a regular octahedron the faces are congruent equilateral triangles and may be considered to consist of two equal pyramids opposing each other on the same square base. —**octahedral** *adj.*

octamer 1 an eight-base sequence element that is common in eukaryotic promoters. The consensus sequence is ATTTGCAT. It binds a number of transcription factors (*see* **OCT**). **2** any polymer of a protein having eight subunits, e.g. β -lactoglobulin at pH 4.7 below 4°C. **3** an assembly of eight **histones** containing two each of H2A, H2B, H3, and H4, that forms the histone core of the nucleosome.

octanoate or (*formerly*) **caprylate 1** *systematic and preferred name for* the anion, CH₃-(CH₂)₆-COO⁻, derived from octanoic acid (*formerly* known as caprylic acid). **2** any mixture of octanoic acid and its anion. **3** any salt or ester of octanoic acid.

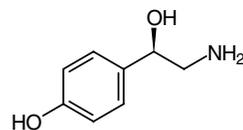

octanoyl or (*formerly*) **capryloyl** or **caprylyl** *symbol*: Oco; the univalent acyl group, CH₃-(CH₂)₆-CO-, derived from octanoic acid (*formerly* known as caprylic acid).

octet 1 any group of eight. **2** (*in chemistry*) (esp. valency) a stable group of eight electrons constituting an electron shell of an atom.

octo+ *a variant form of* **octa+**.

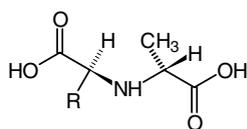

octonic acid any monocarboxylic **aldonic acid** formally derived from an octose by oxidation at C-1.

octopamine β -hydroxytyramine; 1-(*p*-hydroxyphenyl)-2-aminoethanol; the D(-)-enantiomer is a biogenic amine, about one-tenth as active as norepinephrine, formed by the β -hydroxylation of tyramine by dopamine β -hydroxylase. It is found in the salivary glands of *Octopus* spp. and of *Eledone moschata*.

R(-)-enantiomer

octopine 1 *N*-(1-carboxy-4-guanidinobutyl)-L-alanine; *N*²-(1-carboxyethyl)-L-arginine; D-octopine (i.e., *N*²-(D-1-carboxyethyl)-L-arginine) is an **opine** found in the tumours of crown-gall disease in plants and in the muscles of certain invertebrates. The genes responsible for the synthesis of octopine are part of the **T-DNA** from a **Ti-plasmid**. **2** any opine that, like octopine itself, is an *N*-substituted derivative of alanine. Octopine was first isolated from the muscles of *Octopus*, but is found in other cephalopod species and lamelli-branches. The guanidine group can undergo phosphorylation to phosphooctopine, which acts as a **phosphagen**. *Compare* **octopinic acid**.

D-octopine

octopinic acid *N*-(1-carboxy-4-aminobutyl)-L-alanine; *N*²-(1-carboxyethyl)-L-ornithine; D-octopinic acid (i.e., *N*²-(D-1-carboxyethyl)-L-ornithine) is an **opine** found in the tumours of crown-gall disease of plants; it is a member of the **octopine** (def. 2) family.

octose any **aldose** having a chain of eight carbon atoms in the molecule.

octreotide a synthetic octapeptide analogue of somatostatin, with which it shares four residues essential for activity. It has a much longer half-life *in vivo* (1–2 h) than somatostatin (1–2 min) and has been used in the therapy of breast, ovarian, prostatic, gut, endocrine, and pituitary tumours.

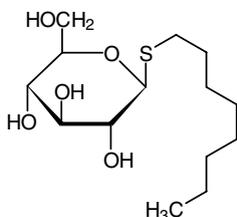

octulose any **ketose** having a chain of eight carbon atoms in the molecule.

octyl *symbol*: Oc; the alkyl group, CH₃–[CH₂]₆–CH₂–, derived from octane.

octyl glucoside *n*-octyl β-D-glucopyranoside; a mild nonionic detergent, aggregation number 84, CMC 20–25 mM. The α-glucoside isomer has also been used, e.g. for crystallization of membrane proteins. The lack of absorbance at 228 nm is an advantage in the use of these compounds. *Compare* **heptyl glucoside**, **hexyl glucoside**, **nonyl glucoside**, **octyl maltoside**.

octyl maltoside *n*-octyl β-D-maltopyranoside; a mild nonionic detergent, CMC 23 mM. *Compare* **octyl glucoside**.

octyl thioglucoside *n*-octyl 1-thio-β-D-glucopyranoside; a mild nonionic detergent, CMC 9 mM, with properties similar to other alkyl glucosides.

ocular 1 of or concerned with the eye or vision. **2** *or* **eyepiece** the lens or system of lenses in an optical instrument (especially a compound microscope) that is positioned nearest to the eye.

oxytocin (*sometimes*) a variant spelling of **oxytocin**.

od *or* **o.d.** *abbr.* for outside diameter.

OD *or* **O.D.** *abbr.* for optical density (now called **absorbance**).

odorant-binding protein any of a family of some 10 proteins that bind and transport odorant molecules across the mucus layer that covers odour receptors in the nasal mucosa. They are homodimers that contain an odorant-binding domain and a dimerization region.

odorant receptor any G-protein-coupled membrane receptor that binds and elicits the biological response of an odorant molecule. Several hundred genes for such receptors are present in the human genome. The receptors function through G_{olf}, which activates adenylate cyclase, or G_{αp}, which activates phospholipase C. They are present in cells of the olfactory system and also outside it (there are over 50 different receptors in spermatogenic cells).

Oe *symbol* for oersted.

oedema an alternative spelling (*esp. Brit.*) of **edema**.

oenanthate an alternative spelling (*esp. Brit.*) of enanthate (*see* **heptanoate**).

oenology an alternative spelling (*esp. Brit.*) of **enology**.

oersted *symbol*: Oe; the cgs unit of magnetizing force or magnetic field strength;

$$1 \text{ oersted} = 10^3/4\pi \text{ amperes per metre} (= 79.58 \text{ A m}^{-1}).$$

[After Hans Christian Oersted (1777–1851), Danish physicist and chemist who discovered the phenomenon of electromagnetism.]

17β-oestradiol an alternative spelling (*esp. Brit.*) of **17β-estradiol**.

OEt *symbol* for the ethoxy group, CH₃–CH₂–O– (alternative to EtO).

OFAGE *abbr.* for orthogonal field alternating gel electrophoresis; a type of **pulsed field gel electrophoresis** used for separating megabase-sized DNA molecules.

off-rate the constant, *k*_{–1}, for the dissociation step in any binding equilibrium, e.g. LB → L + B in the equilibrium L + B = LB, where L represents ligand and B the molecule it binds; the rate of dissociation of a ligand from the bound complex. The dimensions of *k*_{–1} are time^{–1}. *Compare* **dissociation constant**, **on-rate**.

OGCP *abbr.* for oxoglutarate/malate carrier protein; a mitochondrial inner membrane integral protein that plays an important role in several processes, including the malate–aspartate shuttle, gluconeogenesis from lactate, and nitrogen metabolism. *See also* **mitochondrial carrier proteins**.

+ogen a variant form of **+gen** (after a consonant).

Ogston concept *or* **three-point attachment hypothesis** a concept formulated to explain the inherent differing reactivities, often expressed in an enzymic reaction, of identical chemical groups in a **prochiral** molecule. It states that there must be at least three points of attachment of a substrate molecule to the active site of an enzyme. It is similar to the **Easson–Stedman model**. [After Alexander George Ogston (1911–96), British biophysicist who formulated it in 1948.]

Oguchi disease *see* **arrestin**.

25-OHD₃ *abbr.* for 25-hydroxycholecalciferol; calcidiol; use not recommended.

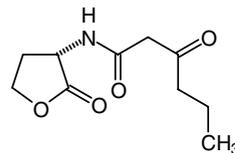

1,25-(OH)₂D₃ *abbr.* for 1,25-dihydroxycholecalciferol; **calcitriol**; use not recommended.

24,25-(OH)₂D₃ *abbr.* for 24(R),25-dihydroxycholecalciferol; (24R)-hydroxycalcidiol; use not recommended.

25,26-(OH)₂D₃ *abbr.* for 25,26-dihydroxycholecalciferol; 26-hydroxycalcidiol; use not recommended.

1,24,25-(OH)₃D₃ *abbr.* for 1,24(R),25-trihydroxycholecalciferol; **calcitriol**; use not recommended.

OHHL *abbr.* for *N*-(3-oxohexanoyl)-L-homoserine lactone.

ohm *symbol*: Ω; the SI derived unit of electric resistance, defined as the resistance between two points on a conductor through which a current of one ampere flows as the result of a potential difference of one volt applied between the points, the conductor not being the source of any electromotive force; i.e. 1 Ω = 1 VA^{–1}. [After Georg Simon Ohm (1787–1854), German physicist.]

Ohm's law a law stating that under constant conditions the current, *I*, flowing through a given conductor is proportional to the potential difference, *U*, applied across it. The law is often expressed in the form *U* = *IR*, where the proportionality constant, *R*, is the resistance of the conductor.

+oic *suffix* (*in chemical nomenclature*) denoting the carboxyl group, –COOH. It is added to the systematic name of an unbranched alkane (or substituted alkane) to denote its modification to the corresponding alkanic (i.e. carboxylic) acid by formal conversion of a methyl group to a carboxy group; e.g. hexanoic acid, CH₃–[CH₂]₄–

COOH, formally derived from hexane, $\text{CH}_3\text{---}[\text{CH}_2]_4\text{---CH}_3$. It is used also in the trivial names of certain carboxylic and heterocyclic carboxylic acids; e.g. benzoic acid, furoic acid.

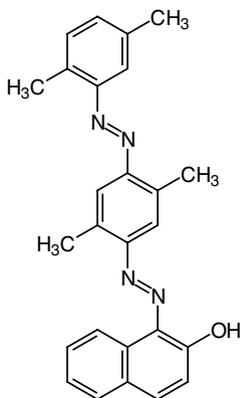

+oid *suffix forming adjectives and (associated) nouns* **1** denoting likeness to, or having the form of (something specified); e.g. colloid (i.e. glue-like substance). **2** generated by rotation of (the geometrical figure specified); e.g. ellipsoid (i.e. solid figure derived from an ellipse). **3** belonging to the class or group represented by (the type member specified); e.g. steroid (i.e. compound belonging to the same chemical family as sterols). — **+oidal** *adj.*

oil any neutral, flammable substance that is liquid at room temperature and is characteristically soluble in relatively nonpolar solvents but only sparingly soluble in aqueous solvents. There are three main groups: (1) animal and vegetable oils, which usually consist predominantly of triacylglycerols but may contain varying amounts of fatty-acid esters of other alcohols; (2) mineral oils, derived from petroleum, coal, shale, etc., which consist predominantly of hydrocarbons; and (3) **essential oils**.

oil body *an alternative name for spherosome.*

oil-immersion objective an objective lens in a light microscope designed to be used with a layer of a special oil between the object (or its coverslip) and the lens. The oil is of the same refractive index as the glass of the lens. This arrangement maximizes the numerical aperture and hence the resolving power of the lens.

Oil Red O a stain for lipid it is widely used for staining lipoproteins on cellulose acetate electrophoretic strips.

oilseed rape or **colza** or **canola** the common name for *Brassica campestris*, a species of rape grown as a source of rapeseed oil.

okadaic acid a polyether fatty acid, $M_r = 804.9$, that is a potent inhibitor of **protein phosphatases**, especially the PP-1 and PP-2A types. It is a tumour promoter, and is implicated as the causative agent of diarrhetic shellfish poisoning. Its name derives from *Hilichondria okadaii*, a marine sponge that feeds on *Prorocentrum lima*, a dinoflagellate from which it is isolated. See structure below.

Okazaki fragment or **Okazaki piece** or **Okazaki segment** any of the relatively short polydeoxyribonucleotides that are formed, concomitantly with the continuous replication of one of the two strands of a duplex DNA molecule, as intermediates during the discontinuous replication of the other strand. Such fragments are synthesized from mononucleotides in a direction opposite to that of the movement of the replication fork; then, as replication proceeds, they are covalently joined through the action of a polynucleotide ligase to form a long daughter polynucleotide chain, the lagging strand. These fragments appear to be 1000–2000 residues long in *Escherichia coli* and 100–200 residues long in mammalian cells; a proportion of them may have RNA primer attached. [After Reiji Okazaki (1930–1975), Japanese molecular biologist.]

OK cell *abbr. for* opossum kidney cell; any cell of a culture derived from this organ and used to study α_{2C} adrenoreceptors.

+ol *suffix (in chemical nomenclature)* indicating the presence of a hydroxyl group attached to a carbon atom.

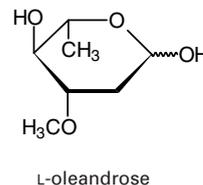

OLA *abbr. for* oligonucleotide ligation assay.

+olate *suffix* used as an alternative to **+oxide** (def. 1).

old yellow enzyme *an obsolete name for* the enzyme NADPH dehydrogenase (EC 1.6.99.1), a yellow flavoprotein (FMN in yeast, FAD in plants). *Compare* **new yellow enzyme**.

Ole *symbol for* the oleoyl (i.e. (Z)-octadec-9-enoyl) group.

oleandrose 2,6-dideoxy-3-O-methyl-arabino-hexose; the L enantiomer is a component of some **cardiac glycosides**.

L-oleandrose

oleate **1** *numerical symbol:* 18:1(9); *the trivial name for* Z-octadec-9-enoate, $\text{CH}_3\text{---}[\text{CH}_2]_7\text{---CH=CH---}[\text{CH}_2]_7\text{---COO}^-$ (*cis* isomer), the anion derived from oleic acid (i.e. Z-octadec-9-enoic acid), a monounsaturated straight-chain higher fatty acid. *See also* **octadecenoic acid**, **oleic family**. **2** any mixture of free oleic acid and its anion. **3** any salt or ester of oleic acid. *Compare* **elaidate**, **vaccenate**.

oleate desaturase *see* **phosphatidylcholine desaturase**.

olefin *an older name for* an alkene. — **olefinic** *adj.*

oleic family (of polyunsaturated fatty acids) a series of polyenoic acids in which the hydrocarbon chain terminates with the alkenyl grouping $\text{CH}_3\text{---}[\text{CH}_2]_7\text{---CH=CH-}$ (as in oleic acid); there are three other series, i.e. the **linoleic family**, **linolenic family**, and **palmitoleic family**. The oleic family can be synthesized from acetyl-CoA: palmitoyl-CoA is first synthesized by the fatty-acid synthase (*see* **fatty-acid synthase complex**); next, by chain elongation and action of **desaturases**, stearoyl-CoA, oleoyl-CoA, and longer chain fatty acyl-CoA compounds are synthesized; then from their respective CoA derivatives, the cognate fatty acids are formed. The series includes (*all-Z*)-eicosa-5,8,11-trienoic acid. In **essential fatty acid deficiency** in mammals, longer chain polyunsaturated fatty acids of the oleic family are synthesized, and partially substitute for long-chain polyunsaturated fatty acids of the linoleic family. *See also* **eicosenoic acid**, **eicosatrienoic acid**, **Mead acid**.

olein *an old name for* any of the glyceryl esters of oleic acid (*see* **oleate**), especially the triester, **triolein** (i.e. trioleylglycerol).

oleo (*US*) *abbr. for* oleomargarine.

oleomargarine *an alternative name (esp. US) for* margarine.

oleosin any of a family of integral membrane proteins (15–25 kDa) of the endoplasmic reticulum in cells of oilseeds that define the accumulation of triacylglycerols and formation of oil bodies (or spherosomes). Oleosins each consist of a conserved central hydrophobic region (70–80 residues) flanked by hydrophobic termini.

oleosome *an alternative name for* spherosome.

oleoyl or (formerly) **oleyl** *symbol:* Ole; *the trivial name for* (Z)-octadec-9-enoyl, $\text{CH}_3\text{---}[\text{CH}_2]_7\text{---CH=CH---CO-}$ (*cis* isomer), the acyl group derived from oleic acid (i.e. (Z)-octadec-9-enoic acid). It occurs very widely in natural lipids. *Compare* **elaidoyl**, **vaccenoyl**. *See also* **oleic family**.

1-oleoyl-2-acetylgllycerol *abbr.:* OAG; an activator of protein kinase C.

oleum fuming sulfuric acid; a solution of SO_3 in concentrated $\text{H}_2\text{SO}_4 \rightarrow \text{H}_2\text{S}_2\text{O}_7$.

oleyl **1** *a common name for* Z-octadec-9-enyl, $\text{CH}_3\text{---}[\text{CH}_2]_7\text{---CH=CH---}[\text{CH}_2]_8\text{---}$ (*cis* isomer), the monoalkenyl group derived from Z-octadec-9-ene; use deprecated. **2** *an old and misleading trivial name for* Z-octadec-9-enoyl; oleoyl now used.

olfactomedin a major glycoprotein component of the extracellular matrix of olfactory neuroepithelium.

olfactory receptor any integral membrane protein thought to be involved in effecting the sense of smell. They are G-protein-associated receptors, and the human genome contains several hundred genes for such receptors.

+olide *suffix* (to the chemical name of an aliphatic hydrocarbon) de-

noting conversion to a lactone having the same number of carbon atoms as the parent hydrocarbon.

oligo *abbr. (colloquial) for oligonucleotide.*

oligo+ or (before a vowel) **olig+** *comb form* denoting **1** few, little, not much, or not many. **2** (in chemistry and biochemistry) a small number of (the component specified); e.g. **oligopeptide**. **3** (in pathology) deficiency or insufficiency of (some thing or some attribute); e.g. **oliguria**. Compare **multi+**, **poly+**.

oligo-2',5'-adenylate synthetase an enzyme of the sub-subclass EC 2.7.7 that binds double-stranded RNA and polymerizes ATP into pppA(2'p5'A)_n oligomers; the latter activate the latent RNase L causing it to cleave single-stranded RNAs. The enzyme is induced by **interferons**. It is a homotetramer, associated with many different subcellular fractions. In humans, two forms, E16 and E18, are produced by alternative splicing of the same gene.

oligodendrocyte a type of glial cell that forms and supports the myelin sheath around axons in the central nervous system of vertebrates. In contrast to the **Schwann cell**, which performs this role in peripheral neurons for a single axon, one oligodendrocyte is involved in the myelination of several axons.

oligo dT or **oligo(dT)** a short single-stranded sequence of deoxythymine (dT), 12–18 nucleotides or longer, used for priming reactions catalysed by reverse transcriptase. The transcript is primed in the poly(A) tail of mRNA molecules.

oligo dT cellulose or **oligo(dT)-cellulose** short single-stranded sequences of deoxythymine (oligo dT) immobilized on cellulose particles and used as an affinity chromatography matrix for the purification of poly(A)⁺ RNA.

oligo-1,6-glucosidase (EC 3.2.1.10), *other names*: sucrose-isomaltase; limit dextrinase; isomaltase; an enzyme that catalyses the hydrolysis of 1,6- α -D-glucoside linkages in isomaltose and dextrans produced from starch and glycogen by α -amylase. A similar enzyme (EC 3.2.1.48) is a type 2 transmembrane protein of the human intestinal brush border. This contains two catalytic domains that share 40 homology. Congenital sucrose-isomaltase deficiency is rare and is genetically heterogeneous.

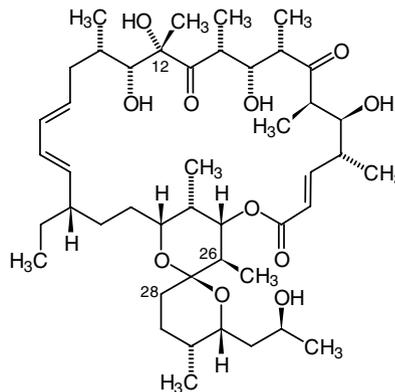

oligohistidine the homopolypeptide of histidine; the term is used in referring to a **histidine tail**.

oligomer 1 (in chemistry and biochemistry) any substance or type of substance that is composed of molecules containing a small number – typically two to about ten – of constitutional units in repetitive covalent linkage; the units may be of one or of more than one species. Depending on the branch of chemistry concerned, an oligomer may or may not be considered to be a variety of **polymer**. **2** (in molecular biology and enzymology) any multimeric protein that contains a finite, relatively small, number of identical subunits (i.e. protomers) that are not in covalent linkage but in a state of reversible association with each other; the protomers may themselves each consist either of single polypeptide chains (i.e. monomers) or of two or more reversibly associated (identical or nonidentical) monomers. This definition is based exclusively on the identity of the subunits and does not restrict the number of polypeptide chains each identical subunit may contain. —**oligomeric** *adj.*; **oligomerize** or **oligomerise** *vb.*; **oligomerization** or **oligomerisation** *n.*

oligomycin any **macrolide** antibiotic produced by an actinomycete similar to *Streptomyces diastatochromogenes*. Oligomycin B is an inhibitor of oxidative phosphorylation in mitochondria, interfering

with the passage of hydrons through the F₀ component of **H⁺-transporting ATP synthase**, and of photophosphorylation in chloroplasts. Oligomycin D (**rutamycin**) is useful as an antifungal agent.

oligomycin sensitivity-conferring protein *abbr.*: OSCP; a protein component of mitochondrial ATP synthase that is required for the binding of the F₁ component to the F₀ component of the enzyme system. See also **H⁺-transporting ATP synthase**.

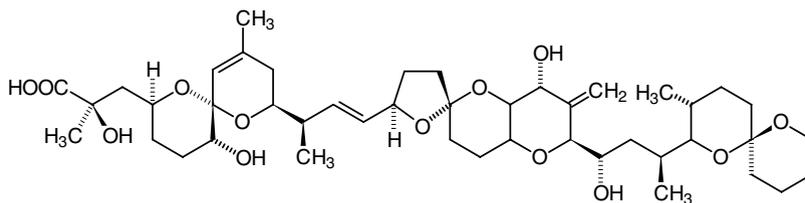

oligomycin A
oligomycin B: 28-oxo
oligomycin C: 12-deoxy
oligomycin D: 26-demethyl

oligonucleotide *abbr. (colloquial)*: oligo; any molecule that contains a small number of nucleotide units connected by phosphodiester linkages between (usually) the 3' position on the glycoside moiety of one nucleotide and the 5' position of the glycoside moiety of the adjacent one. The number of nucleotide units in these small single-stranded nucleic acids (usually DNA) is variable but often in the range of 6 to 24 (hexamer to 24mer), although for some purposes it might be as long as 50mer. They are widely used as primers for reactions catalysed by DNA polymerases.

oligonucleotide-directed mutagenesis a method for introducing a mutation into a cloned gene in which the desired sequence alteration is incorporated into an oligonucleotide. The mutant oligonucleotide is annealed to its complementary sequence in the cloned gene, where it acts as a primer for DNA polymerase-catalysed transcription of a complementary strand of the gene of interest, and the plasmid in which it is cloned. A number of methods have been developed to ensure that the nonmutagenized strands of the original duplex are not propagated when used to transform *E. coli* cells.

oligonucleotide ligation assay *abbr.*: OLA; a method for detecting genetic variants that differ at only one base pair. A pair of oligonucleotides are designed so that they are contiguous when annealed to the template DNA strand and with the innermost 3' end of one oligonucleotide in register with the point of sequence variation. Oligonucleotides designed to detect the normal sequence are then ligated by the action of a thermostable DNA ligase. Another pair of oligonucleotides are designed to be ligated when annealed to the mutant or polymorphic sequence. There will be a mismatch be-

okadaic acid

tween the innermost 3' end of the 'normal' oligonucleotide and the mutant sequence, and between the 'mutant' oligonucleotide and the normal sequence so that in either case they will not be ligated to the contiguous oligonucleotide of the pair. Biotin at the outer 3' end of the oligonucleotide pair and a hapten at the outermost 5' end of the oligonucleotide pair are covalently linked if ligation takes place. Reaction products are immobilized by transferring them to streptavidin coated microtitre plates, washed and probed with anti-hapten antibody coupled to an enzyme such as alkaline phosphatase. A positive enzyme-catalysed reaction gives evidence of ligation of a particular oligonucleotide pair and hence for the cognate DNA sequence.

oligopeptide any molecule that contains a small number (2 to about 20) of amino-acid residues connected by peptide linkages.

oligophosphate 1 any ion or salt of an **oligophosphoric acid** — an acid containing commonly two or three, but sometimes four or more, phosphoric residues connected by anhydride linkages. **2** any mixture of a free oligophosphoric acid and its various anions. **3** or **oligophosphoric ester** any ester of an oligophosphoric acid.

oligophrenin-1 the protein product of a human gene associated with a form of X-chromosome-linked mental retardation.

oligosaccharide any molecule that contains 2 to about 20 monosaccharide residues connected by glycosidic linkages.

oligosaccharin any of a group of regulatory oligosaccharides, including a fungal heptaglucoide and a plant oligogalacturonide, that are released from cell walls and control functions such as growth, development, reproduction, and defence against disease. They also include xyloglucans.

N-oligosaccharyltransferase an enzyme that transfers an oligosaccharide with high mannose content from a lipid-linked oligosaccharide donor to an asparagine acceptor site on newly synthesized polypeptides to form glycoproteins. It has three subunits: **ribophorins I and II**, and a 48 kDa subunit.

oligotrophic describing a habitat, especially a lake or other mass of water, that is poor in nutrients capable of supporting the growth of aerobic plants and microorganisms, and (in the case of a lake, etc.) that hence contains abundant dissolved dioxygen at all depths.

olivomycin one of several related components of a complex of antibiotics produced by *Streptomyces olivoreticuli*. It has been investigated for antineoplastic activity. It is used as a dye specific for G-C base pairs, and stains the R bands first demonstrated in Giemsa staining.

+oma (*pl.* **+omas** or **+omata**) *suffix* denoting a tumour.

+ome *suffix forming nouns 1* denoting an inclusive class of cellular constituents (e.g. metabolome, proteome, transcriptome) by analogy with genome. **2** denoting an entire set or a whole sphere of activity; universal. *See also* **+omics**. **-+omic adj.**; **-+omically adv.**

OMe *symbol* for the methoxy group, CH₃-O- (alternative to MeO).

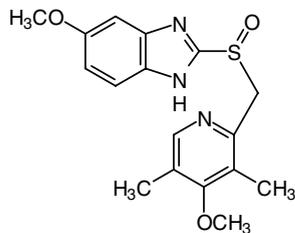

omega *symbol*: ω (lower case) or Ω (upper case); the twenty-fourth and last letter of the Greek alphabet. For uses *see* **Appendix A**.

Omega *an alternative name for* **Mega-8**.

omega-oxidation or **ω-oxidation** a minor oxidative metabolic pathway of fatty acids, particularly those of medium chain-length, in which the terminal methyl group of such an acid is oxidized first to a hydroxymethyl group and ultimately to another carboxyl group.

omega protein or **ω-protein** *an alternative name for* type I **DNA topoisomerase**.

omeprazole *the nonproprietary pharmaceutical name for* 5-methoxy-2- [(4-methoxy-3,5-dimethyl-2-pyridinyl)methyl]sulfinyl-1H-benzimidazole, a gastric proton-pump inhibitor. It blocks both basal and stimulated secretion of acid in the stomach by reversibly inhibiting H⁺/K⁺-transporting ATPase (EC 3.6.1.36) in the plasma membranes of parietal cells within the oxyntic glands of the gastric mucosa. It is useful clinically in the treatment of erosive reflux esophagitis, benign peptic ulcer, and Zollinger–Ellison syndrome. *Proprietary name*: Losec.

omeprazole

omicron *symbol*: o (lower case) or O (upper case); the fifteenth letter of the Greek alphabet.

+omics *suffix forming nouns* used to denote rigorous, systematic analyses of the omes: e.g., proteomics, analysis of the proteome using 2D gel electrophoresis and mass spectrometry to separate, identify and characterize all the constituent proteins; metabolomics, quantitative analysis of all the small molecular weight metabolites present inside a cell (or other sample); pharmacogenomics, analysis of drug responses with respect to genomic information (e.g., polymorphisms), aiming to customize therapies and reduce adverse drug reactions; toxicogenomics, analysis of the toxic effects of potential new drugs on gene expression patterns in target cells or tissues, aiming both to prioritize compound pipelines (to eliminate expensive failures in drug development), and to reveal genetic signatures that may predict toxicity in these compounds. *See* **ome**.

OMIM *abbr. for* Online Mendelian Inheritance in Man; *see* **specialist database**.

ommatidium any of many identical structural units of the compound eye found in many invertebrates. In *Drosophila*, each consists of eight photoreceptor cells and 12 accessory cells. In sevenless and bride-of-sevenless mutants, one of the photoreceptor cells fails to develop.

ommatin a type of **ommochrome**.

ommatochrome *an alternative name for* **ommochrome**.

ommin a type of **ommochrome**.

ommochrome or **ommatochrome** any yellow, brown, red, or violet natural polycyclic pigment especially common in the Arthropoda, particularly in the ommatidia of the compound eye. Ommochromes contain a phenoxazine nucleus and are formed biologically from tryptophan via kynurenine. They are divided into two groups: **ommatins**, which are alkali-labile, of low relative molecular mass, and rather weakly coloured; and **ommins**, which are alkali-stable, of higher relative molecular mass, and more strongly coloured than the ommatins.

OMP *abbr. for* orotidine monophosphate; *see* **orotidine phosphate**.

OMP decarboxylase *abbr. for* orotidine-5'-phosphate decarboxylase, a catalytic activity present in a domain of the multifunctional enzyme **uridine 5'-monophosphate synthase**.

+onate *noun suffix* denoting the anion, a salt, or an ester of an aldonic acid. *See also* **uronate**.

onco+ *comb. form* denoting **1** tumour. **2** volume.

oncofetal parvalbumin *see* **oncomodulin**.

oncogen any agent that causes **oncogenesis**; the term embraces **carcinogen**.

oncogene any gene associated with the causation of cancer. The first oncogenes were isolated from acutely transforming **retroviruses**; the retroviral oncogenes (*v-onc*) were then found to be related to, and probably derived from, normal cellular genes (*c-onc*), which came to be termed **protooncogenes**; these in most cases are involved with intrauterine growth control. Protooncogenes become oncogenes as a result of (1) deletions of portions of the protooncogene; (2) mutation of the protooncogene resulting in a protein that is constitutively active; (3) translocation of the protooncogene or a part of it to produce a hybrid gene and a hybrid protein with aberrant

function; or (4) amplification of the gene resulting in inappropriate expression of the product. Protooncogenes function in normal cells in growth and differentiation pathways. Some have products that act as growth factors (e.g. *sis*, *int-2*) or growth-factor receptors (e.g. *fms*, *neu*, *kit*). Others encode signal-transduction molecules normally activated by growth-factor receptors (e.g. *ras*, *raf*, *mos*, and *src* family members). Others encode proteins that function in the nucleus (e.g. *myc*, *myb*, *fos*, *jun*) where they influence the expression of other genes. For further details see under individual oncogenes. Strictly speaking, those genes carried by DNA tumour viruses, such as **SV40** and **adenoviruses**, should also be construed as oncogenes. Unlike the retroviral genes, however, they appear to have no cellular counterparts but instead operate by subverting the actions of cellular genes (such as protooncogenes) that normally function to control cell growth. See also **FMS**, **FOS**, **int-2**, **JUN**, **KIT**, **MOS**, **MYB**, **MYC**, **neu**, **RAF**, **RAS**, **sis**, **src**.

oncogenesis the production or formation of a neoplastic tumour, whether benign or malignant; the term embraces **carcinogenesis**.

oncogenic (of an agent) causing the formation of a neoplastic tumour or tumours; of or pertaining to **oncogenesis**; the term embraces carcinogenic. —**oncogenicity** *n*.

oncology the branch of medicine concerned with the study and treatment of neoplastic tumours. —**oncological** *adj.*; **oncologist** *n*.

oncolysis the destruction of neoplastic tumours or tumour cells, whether spontaneous or in response to treatment. —**oncolytic** *adj.*

oncomodulin *other names:* parvalbumin beta; oncofetal parvalbumin; an **EF-hand** Ca²⁺-binding protein that may function in a similar manner to **calmodulin**. Expression is limited to early embryonic stages, the placental cytotrophoblasts and neoplastic tissues.

oncoprotein any protein that is the product of an **oncogene**. There are some 100 potential oncogenes in the human genome, and their products have various functions. These include growth-factor-related functions; as protein tyrosine kinases (receptor, membrane-associated, or cytosolic); as nonprotein tyrosine kinase receptors; as membrane-associated G proteins; as cytosolic protein serine/threonine kinases; as cell-cycle regulators; as transcription factors; in DNA repair; or mitochondrial-membrane related.

oncornavirus *an old name for* a group of RNA tumour viruses now classified in the subfamily Oncovirinae. See **retrovirus**.

oncostatin M *abbr.:* OSM; a polypeptide cytokine, produced by activated T cells and PMA-treated monocytes, that inhibits the growth of a variety of cancer cells, but stimulates growth of AIDS-Kaposi's sarcoma-derived cells and normal fibroblasts. It is a member of the **interleukin 6** subfamily. It exists as a monomer.

oncotic pressure the **colloid osmotic pressure** of plasma proteins; it is important as an index of the flow of water between the blood and the fluid in the tissues.

+one *noun suffix* denoting ketone.

one-carbon compound *an alternative name for* **C₁ compound**.

one cistron—one polypeptide hypothesis *an alternative name for the one gene—one polypeptide hypothesis*.

one gene—one antigen hypothesis a hypothesis stating that each of the genes in a tissue transplant governing the host's reaction to it is responsible for the manufacture of a particular transplantation antigen and for that antigen alone. It was first formulated by the US geneticist George Wells Beadle (1903–89) and US microbiologist Edward Lawrie Tatum (1909–75).

one gene—one enzyme hypothesis a hypothesis stating that every enzyme is synthesized under the control of a specific gene. It was subsequently refined into the **one gene—one polypeptide hypothesis**.

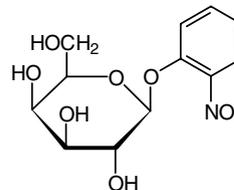

one gene—one polypeptide hypothesis *or one cistron—one polypeptide hypothesis* a hypothesis stating that each naturally occurring polypeptide is synthesized biologically under the control of a specific gene, which is transcribed into a unique species of messenger RNA.

one gene—one reaction hypothesis a hypothesis stating that every specific biochemical reaction is under the ultimate control of a different gene. It was later redefined as the **one gene—one enzyme hypothesis**.

+onic *suffix* denoting the formal conversion of an aldose to the corresponding aldonic acid; e.g. glucose gives rise to gluconic acid.

+onium *noun suffix* denoting a cationic molecular entity in which a heteroatom is bonded to one more univalent ligand than is normal for a neutral molecule containing that heteroatom and therefore bears a formal positive charge; e.g. ammonium, H₄N⁺; dimethylammonium, (CH₃)₂H₂N⁺; diphenyliodonium, (C₆H₅)₂I⁺; trialkylsulfonium, R₃S⁺ (where R = alkyl). See also **carbonium ion** (def. 2).

ONPG *abbr. for ortho-nitrophenyl-β-D-galactopyranoside*; a chromogenic substrate used for the detection and assay of β-galactosidase activity.

on-rate the constant, *k*₊₁, for the association step L + B → LB in the equilibrium L + B = LB, where L represents ligand and B the molecule it binds; the rate of association of ligand to form a complex. The dimensions of *k*₊₁ are time⁻¹. Compare **association constant**, **off-rate**.

Onsager theory an extension of the **Debye-Hückel theory** of dielectrics. See also **Kirkwood theory**. [After Lars Onsager (1903–76), Norwegian-born US physical chemist.]

ontogeny *or ontogenesis* the sequence of events in the development of an individual organism during its lifetime. Compare **phylogeny**. —**ontogenic** *or ontogenetic* *adj.*

ontology (*in logic*) the formal specification of the terms and concepts used in a field or domain of knowledge providing definitions of those terms and of the relationships between them. —**ontological** *adj.*; —**ontologically** *adv.*

oo+ *comb. form* denoting ovum or egg.

oocyte (*in zoology*) a cell of an animal ovary that undergoes meiosis to form an ovum. A **primary oocyte** is formed by differentiation of an oogonium and then undergoes the first division of meiosis to form a polar body and a secondary oocyte. Following fertilization of the egg, the **secondary oocyte** undergoes the second meiotic division to form the mature ovum and a second polar body.

OODB *abbr. for* object-oriented database.

oogenesis the complete process of formation and maturation of an ovum from a primordial female germ cell. —**oogenetic** *adj.*

oogonium (*pl. oogonia*) **1** (*in zoology*) a cell of an animal ovary that undergoes repeated mitosis, eventually forming **oocytes**. **2** (*in botany*) the female reproductive organ in certain algae and fungi. —**oogonial** *adj.*

OP *abbr. for* organophosphorus. See **organophosphate**.

opal codon *or opal triplet* *symbol:* UGA; one of the three terminator codons or **nonsense codons** in a molecule of messenger RNA.

opalescence a milky iridescence, similar to that of opal. In some solutions it is due to the reflection of light by very fine suspended particles. —**opalescent** *adj.*; **opalesce** *vb.*

opal mutant any cell or virus carrying an **opal mutation**.

opal mutation a mutation that gives rise to an **opal codon** in a molecule of messenger RNA.

opal suppressor a mutation, *supU* (Trp), in *E. coli* that codes for an altered tRNA so that its anticodon can recognize the **opal codon** (UGA) in mRNA thereby allowing insertion of tyrosine into a polypeptide chain at that site.

open chain (*in chemistry*) **1** a chain of atoms in a molecule that is not formed into a ring, i.e. one that has two (or more) free ends. **2** **open-chain** *an alternative term for* **acyclic**.

open circle any circular duplex DNA structure containing one or more single-stranded nicks. Such a structure will dissociate at high pH into two (or more) single-stranded structures.

open circuit (*in physics*) an incomplete electrical circuit, i.e. one with infinite impedance.

open-loop system a type of system, e.g. a metabolic pathway or an

electrical circuit, in which control is not exerted by feedback, each operation or activity being affected only by those earlier in the sequence. *Compare* closed-loop system.

open reading frame *abbr.*: ORF; a series of codon triplets, deduced from a DNA sequence, that include a 5' initiation codon running through to a termination codon, and representing a putative or known gene. For a stretch of DNA to represent a gene it must, apart from including appropriately placed initiation and termination codons, be of a suitable length and should fulfil certain criteria indicating that the correct reading frame has been selected. Methods for checking this include the RYN method.

open system (*in thermodynamics*) any geometrically defined volume that can exchange both energy (e.g. heat or work) and matter with its surroundings. *Compare* adiabatic system, closed system.

open tetrapyrrole *see* phycobillin.

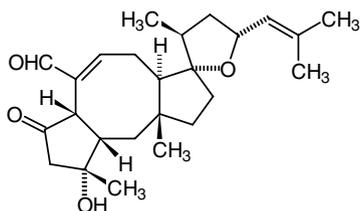

operand a quantity or function on which a mathematical operation is to be performed.

operator 1 (*in genetics*) a DNA sequence within an operon (under negative promoter control) to which a specific repressor protein can bind, thereby regulating the functioning of a structural gene or group of genes. **2** (*in mathematics*) a symbol (i.e. an alphabetic character, term, or special symbol) representing a particular operation to be performed on an operand or operands; e.g. Σ (= sum of), d/dx (= differentiate with respect to the variable x), $+$ (= add to).

operon a unit of coordinated and regulated gene activity found in prokaryotes, by means of which the control of the synthesis of a protein or a group of (usually functionally associated) proteins is determined. It consists of a segment of genomic DNA containing a structural gene or a linear sequence of structural genes (which are transcribed as a single unit), together with one or more regulatory regions such as an operator (def. 1). *See also* Jacob-Monod model, lac operon.

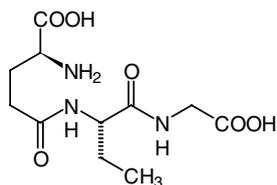

ophidin a trivial name for 2-methylcarnosine; N^α -(β -alanyl)-2-methylhistidine; a constituent of snake muscle.

ophiobolin a class of sesterterpene produced only by fungi; there are six types based on the ophiobolane structure shown.

ophthalmic of, or pertaining to, the eye.

ophthalmic acid N -[N -(γ -glutamyl)- α -aminobutryl]glycine; an analogue of glutathione in which the thiol group is replaced by a methyl group. It was originally isolated from the lens of the eye.

opiate 1 any of a group of narcotic drugs structurally related to and including morphine all of which are derived from opium. The group includes codeine, papaverine, and thebaine. The term is sometimes extended to include the opioids (def. 1) and any other naturally occurring, semisynthetic, or synthetic narcotic substance with similar properties and whose effects may be reversed by recognized mor-

phine antagonists. **2** consisting of or containing opium; having narcotic properties similar to those of opium.

opiate receptor a membrane receptor for opiates (*see* opioid receptor.)

opine any of a class of unusual derivatives of basic amino acids not found in normal plant tissue, but found in plant tissue that has been transformed by oncogenic plasmids from agrobacteria. The class includes the nopaline and octopine families.

opiocortin an alternative name for opiomelanocortin.

opioid 1 any nonalkaloid having opiate-like pharmacological effects that can be reversed by naloxone or other recognized morphine antagonists. **2** describing any substance having such properties.

opioid peptide any naturally occurring peptide that is an opioid (def. 1). Five main groups are recognized: (1) [Leu]enkephalin and [Met]enkephalin; (2) dynorphin, α and β neoeendorphin, and several other peptides that arise (or are presumed to arise) from enkephalin precursors; (3) α , β , γ and δ endorphins, all of which are formed from β lipotropin; (4) various pronase-resistant peptides present in body fluids, e.g. β casomorphin (in bovine milk); (5) sundry other peptides whose opiate-like action appears to be indirect. [Note: in the past, the terms 'endorphin' and 'opioid peptide' were often used synonymously; it is now recommended that the former should be restricted to those opioid peptides that are derived from β lipotropin.]

opioid receptor any G-protein-associated membrane receptor that interacts in a highly selective manner with an opiate or an opioid (def. 1) and that mediates its prime pharmacological action; types μ , δ , and κ , and possibly σ have been distinguished on the basis of their response to β endorphin (End), dynorphin A (Dyn), [Met]enkephalin (Met), and [Leu]enkephalin (Leu); the potency being, for μ : End > Dyn > Met > Leu; for δ : End = Leu = Met > Dyn; and for κ : Dyn >> End >> Leu = Met. Morphine and its analogues are primarily μ agonists, but also have activity on δ and κ receptors. μ and δ depress cyclic AMP levels and open a G-protein-modulated K^+ channel, κ inhibits a G-protein-modulated Ca^{2+} channel. Some opioids also bind to other receptors known as σ , but morphine has a very low affinity for these receptors and naloxone does not block its action.

opiomelanocortin or **opiocortin** a polypeptide, present in the intermediate lobe of the pituitary gland, that includes within it the entire sequences of the peptide hormones corticotropin, α and β melanocyte stimulating hormone, β and γ lipotropin, and β endorphin. It is formed from proopiomelanocortin.

opium the milky, air-dried exudate from incised, unripe seed capsules of the opium poppy, *Papaver somniferum*, and some other species. Opium contains approximately 20 alkaloids, the most significant of which are codeine, morphine, papaverine, and thebaine.

OPLC *abbr.* for overpressure(d) layer chromatography.

OPRTase *see* orotate phosphoribosyltransferase.

opsin 1 any of a group of hydrophobic glycoproteins that occur in the visual pigments of vertebrates in equimolecular combination (as Schiff's bases) either with 11-*cis*-retinal – in iodopsin and rhodopsin – or with 3,4-didehydro-11-*cis*-retinal – in cyanopsin and porphyropsin. These opsins are of ~35–40 kDa, and consist of single-chain polypeptides glycosylated with two branched oligosaccharides. *See also* photopsin, scotopsin. **2** any of a group of proteins of ~25 kDa that occur in combination with retinal in the purple-membrane pigments present in some strains of *Halobacterium halobium*; e.g., bacterioopsin (in bacteriorhodopsin), haloopsin (in halorhodopsin), and slow-opsin (in slow-cycling rhodopsin).

opsonify a less common word for opsonize.

opsonin any blood-serum protein that, when combined with microorganisms or other particulate material (e.g., foreign erythrocytes), increases the latter's susceptibility to phagocytosis. The two main classes are immunoglobulin G antibodies, and the C3b and IC3b fragments formed from the C3 component of complement; other classes include fibronectin and the soluble mannose-binding protein of serum. An opsonin molecule acts by linking the surface of the particulate matter to a specific receptor on the surface of a phagocytic cell; commonly, this receptor is either an Fc receptor (recognizing the Fc domain of an IgG immunoglobulin molecule) or a CR3 receptor (recognizing the IC3b fragment of complement). —opsonic *adj.*

opsonize or **opsonise** or (*less commonly*) **opsonify** to render (microorganisms or other particulate material) more susceptible to phagocytosis by coating with **opsonin**. —**opsonization** or **opsonisation** or **opsonification** *n*.

optic 1 or **optical** of or pertaining to the eye or the sense of sight; aiding vision. **2** a *less common word for optical* (def. 1, 2).

optical 1 or **optic** of, pertaining to, or involving light. **2** or **optic** of or pertaining to **optics**. **3** a *less common word for optic* (def. 1).

optical activity the ability (of chiral substances or their solutions, and chiral crystals) to rotate the plane of polarization of a transmitted beam of plane-polarized light. There is usually a correspondence between **chirality** of molecules and optical activity. *See also chiroptical*.

optical antipode an older term for **enantiomer**.

optical activity a term (no longer recommended) for **absorbance**.

optical isomer an older term for **enantiomer**.

optical isomerism an older term for **enantiomerism**.

optically active having or displaying optical activity; the term is often used interchangeably with **chiral**.

optically inactive lacking optical activity (through being either **achiral** or **racemic**).

optical purity the ratio (usually expressed as a percentage) of the **specific optical rotation** of a sample of an enantiomeric substance to the specific optical rotation of a pure single enantiomer of the substance. *Compare enantiomeric purity*.

optical rotation or **rotation 1** the phenomenon of rotation of the plane of polarization of plane-polarized light on its transmission by (solutions of) chiral substances, and by chiral crystals. By convention, optical rotation is designated as rightwards, or positive – and termed **dextrorotation** – when it is clockwise as seen by an observer looking towards the light source, and designated as leftwards, or negative – and termed **levorotation** – when it is anticlockwise. **2** or **optical rotatory power** the ability of (a solution of) a chiral substance to effect such rotation, an effect that is normally associated with **optical activity**. **3** *symbol*: α ; any measure, expressed in angular degrees, of such ability under specified conditions; *see molar optical rotation, specific optical rotation*.

optical rotatory dispersion *abbr.*: ORD; the variation of **optical rotation** with the wavelength or frequency of the transmitted light. The shape of an optical rotatory dispersion spectrum of a solution of a macromolecule often gives useful information about the conformation of the solute. *See also circular dichroism, Cotton effect*.

optical rotatory power an alternative term for **optical rotation** (def. 2).

optical system any arrangement of diffraction gratings, lenses, mirrors, prisms, etc., frequently within a specific instrument and used for a specific purpose.

optical tweezers a technique for trapping small particles or macromolecules in a strongly focused laser beam. It is used for examination of individual molecules or cellular components, such as contractile proteins, and the forces they produce.

optics 1 (*functioning as sing.*) the branch of physics concerned with the nature, properties, and behaviour of (visible) light and with the characteristics of optical devices, instruments, and systems. The term is extended to other kinds of electromagnetic or particulate radiation in so far as they have similar properties to light. **2** a *collective term for an arrangement of optical components* (in an instrument); the optical properties of such an arrangement.

optineurin a 66 kDa protein of unknown function that is expressed in retina, brain, and various other tissues, and is present in the aqueous humour of eyes of many vertebrate species. It interacts with huntingtin, Rab8 (a Ran-associated protein), and transcription factor IIIA (*see TFIIIA*). It is thought to be neuroprotective in the eye and optic nerve. Several mutations are associated with an autosomal dominant adult-onset glaucoma. [From optic neuropathy-inducing protein.]

OPTLC *abbr.* for overpressured thin-layer chromatography. *See overpressure(d) layer chromatography*.

Oracle *see relational database management system*.

oral of or pertaining to the mouth; administered by mouth.

Orb the *Drosophila* homologue of CPEB of *Xenopus laevis*. It is re-

quired for translation of the mRNA for oskar in oocytes. *See cytoplasmic polyadenylation element*.

orbit 1 a closed circular or near-circular course taken by a moving body (often around something). **2** the depression in the skull that contains the eye. **3** to move in or as if in an **orbit** (def. 1). *See also orbital*.

orbital 1 any **wave function**, Ψ , of an electron in a molecular entity. It is characterized by a particular energy value and a unique set of three quantum numbers; the counterpart in wave mechanical theory of an electron orbit in Niels Bohr's concept of atomic structure. Any particular orbital may be occupied either by one electron or by two electrons of opposed spins, or it may be unoccupied. The square of the value of Ψ at any point can be interpreted as the probability of the electron being located at that point, or as the average fractional charge density at that point. *See also atomic orbital, molecular orbital, pi orbital, sigma orbital*. **2** of, relating to, occupying, or moving in or as if in an **orbit** (def. 1). **3** belonging to the **orbit** (def. 2). **orbital shaker** a device designed to impart an orbital motion to flasks, tubes, etc. with the purpose of mixing their contents and facilitating the transfer of gases from the gaseous to the liquid phase. It is useful especially for growing cultures of cells.

ORC *abbr.* for origin of replication complex or origin recognition complex; *other name*: prereplication complex. A protein complex in eukaryotes, comprising a hexamer of subunits OR11 to OR16, that recognizes and binds to the **origin of replication** region of chromosomal DNA to initiate replication. A replisome is assembled on it. It is regulated by several proteins involved in control of the cell cycle.

orcinol test or **Bial's test** a colorimetric test specific for aldopentoses. The sample is heated with strong acid to convert any aldopentose present to furfural (i.e. 2-furaldehyde), which is then reacted with orcinol (i.e. 5-methyl-1,3-benzenediol) in the presence of ferric chloride to give a blue-green compound extractable into amyl alcohol. The test is used for the determination of RNA and the detection of **pentosuria**. [After Manfred Bial (1870–1908), German physician.]

ORD *abbr.* for optical rotatory dispersion.

Ord *symbol for a residue of the ribonucleoside orotidine* (alternative to O).

order 1 (*in chemistry*) sequence (of residues in a polymer). **2 order of reaction**. **3** (*in taxonomy*) a category consisting of a number of similar families (sometimes only one family). One or more orders make up a class. **4** (*in mathematics*) the number of times a function must be differentiated to obtain a particular derivative. **5** (*in mathematics*) the number of columns or rows in a determinant or a square matrix. **6 order of magnitude**.

ordered mechanism or **ordered pathway** (for an enzymic reaction involving two substrates, $A + B \rightleftharpoons C$) a mechanism in which the enzyme, E, must necessarily first bind to one substrate, e.g. $E + A \rightleftharpoons EA$, and then to the second substrate, thus $EA + B \rightleftharpoons EAB$, this ternary complex then reacting to form the product, $EAB \rightleftharpoons E + C$. *Compare random mechanism*.

order of magnitude 1 a tenfold range of magnitude extending from a particular value either upwards or downwards. **2** a magnitude expressed to the nearest power of ten.

order of reaction *symbol*: n ; the sum of the exponents of the concentration terms in the rate equation for an elementary chemical reaction considered in one direction only. It may also be applied to certain composite reactions.

order of reflection *symbol*: n ; the integer, n , in the equation of **Bragg's law**.

ordinate the vertical, or y , coordinate in a plane rectangular (Cartesian) coordinate system. *Compare abscissa*.

ORESTES an alternative name for **ORF ESTs**.

orexin an alternative name for **hypocretin**.

ORF *abbr.* for open reading frame.

ORF ESTs or **ORESTES** *abbr.* for open reading frame expressed sequence tags; expressed sequence tags (ESTs) that provide sequence information along the whole length of a transcript, rather than just its ends. The method involves low-stringency polymerase chain reaction (PCR) to produce cDNA libraries, samples of which are then sequenced.

organ any part of the body of a multicellular organism that is

adapted and/or specialized for the performance of one or more vital functions. The term is sometimes extended to include organelles of unicellular organisms.

organ culture a category of **tissue culture**, in which an organ, part of an organ, or an organ primordium, after removal from an animal or plant, is maintained *in vitro* in a nutrient medium with retention of its structure and/or function.

organelle any discrete structure in a unicellular organism, or in an individual cell of a multicellular organism, that is adapted and/or specialized for the performance of one or more vital functions.

organic **1** of, pertaining to, or derived from an organism or organisms. **2** of, pertaining to, or affecting an organ or organs. **3** of, relating to, or being a compound of carbon, whether or not of natural origin. **4** of any element contained in an organic compound. **5** any organic compound.

organic chemistry the branch of chemistry concerned with the compounds of carbon in covalent linkage, whether natural or artefactual, including most compounds of biological origin but excluding some simple carbon compounds, e.g. oxides, sulfides, and cyanides. *See also* **organic compound**.

organic compound any compound containing carbon in covalent linkage; various simple carbon compounds, especially carbon dioxide, carbonic acid, and salts and ions of carbonic acid, are usually excluded.

organification defect a defect in the iodination of tyrosine residues in thyroglobulin and in their coupling to produce thyroid hormones. It causes a congenital form of hypothyroidism. The reactions are catalysed by thyroperoxidase.

organiser a variant spelling of **organizer**.

organism any unicellular or multicellular prokaryote or eukaryote, usually extended to include various noncellular nucleic-acid-containing infective agents such as viruses.

organizer or **organiser** (*in embryology*) any part of an embryo that, through substances produced by it, stimulates the morphological development and differentiation of other parts.

organo+ *comb. form* denoting **organic** (def. 1, 2, 3).

organogenesis the formation and development of organs in an organism. —**organogenetic** *adj.*

organoleptic affecting, involving, or making use of the sense organs, especially those of smell and taste.

organomercurial **1** or **organomercury** of, pertaining to, or being an organic compound containing mercury, especially one in which a mercury atom is linked directly to one or more carbon atoms. **2** or **organomercury compound** any such compound.

organometallic **1** or **organometal** of, pertaining to, or being a metal-containing organic compound, especially one in which a metal atom is linked directly to one or more carbon atoms. **2** or **organometal compound** any such compound.

organophosphate any organic compound containing a phosphoric (including fluorophosphoric, thiophosphoric, etc.) residue in amide, anhydride, ester, or thioester linkage. The best known is diisopropylphosphofluoridate, which inhibits serine proteases (including acetylcholinesterase, crucial for nerve transmission) by blocking an essential serine residue. Organophosphorus compounds were originally developed as nerve gases, and later used as agricultural insecticides and as anthelmintics. *See also* **aminoethylbenzenesulfonyl fluoride**, **diisopropyl fluorophosphonate**, **phenylmethylsulfonyl fluoride**.

organotroph an alternative term for **heterotroph(e)**.

organotrophic **1** heterotrophic; *see* **heterotroph(e)**. **2** of, pertaining to, or influencing the formation or nourishment of bodily organs.

organyl any organic substituent group, regardless of functional type, that has a single free valence at a carbon atom; e.g. ethyl, CH_3CH_2- ; glycol, $\text{H}_2\text{NCH}_2(\text{=O})-$; ribosyl, $\text{C}_5\text{H}_9\text{O}_4-$.

ORI *abbr.* for origin of replication.

oriC an AT-rich region of 245 bp on the *E. coli* chromosome where DNA replication is initiated. Elements of the sequence are highly conserved among Gram-negative bacteria. A complex of DNA proteins (up to 30 subunits) binds to *oriC* causing the duplex DNA to melt using energy released by ATP hydrolysis.

origin (*in mathematics*) the point of intersection of a set of (usually

two or three) coordinate axes; the point whose coordinates are all zero. —**original** *adj.*

origin of replication *abbr.*: ORI; a site on DNA at which DNA replication begins. Eukaryotic chromosomes contain many such sites, whereas prokaryotic chromosomes, mitochondrial DNA, and chloroplast DNA contain only one. ORIs are AT-rich. Most contain repetitive nucleotide sequence motifs that vary in sequence, length, and distribution in different organisms; most also contain inverted repeats of various sizes. *See* **replication of DNA**.

origin of replication complex *see* **ORC**.

origin recognition complex *see* **ORC**.

O-ring a toroidal ring, usually of circular cross-section, made of neoprene or similar material and useful as a fluid- or gas-tight seal between particular parts of a device while permitting relative movement between them.

Orlistat another name for **Xenical**.

Orn *symbol* for a residue of the α -amino acid L-ornithine.

ornaline an alternative name for **nopalinic acid**.

ornithine *symbol*: Orn; α,δ -diaminovaleric acid; 2,5-diaminopentanoic acid; an amino acid only rarely found in proteins. L-Ornithine is an intermediate in the biosynthesis of arginine (*see* **ornithine-urea cycle**) and, in plants, of pyrrolidine and tropane alkaloids; it was first found as its dibenzoyl conjugate, **ornithuric acid**. D-ornithine is a component of **bacitracin A**.

ornithine acetyltransferase *see* **glutamate N-acetyltransferase**.

ornithine- δ -aminotransferase *see* **OAT**.

ornithine carbamoyltransferase *abbr.* (*in clinical chemistry*): OCT; EC 2.1.3.3; *systematic name*: carbamoyl-phosphate:L-ornithine carbamoyltransferase; *other names*: ornithine transcarbamylase; citrulline phosphorylase. An enzyme of the **ornithine-urea cycle** that catalyses a reaction between carbamoyl phosphate and L-ornithine to form L-citrulline and orthophosphate. It is a homotrimer of the mitochondrial matrix. More than a hundred point mutations and gene deletions cause an X chromosome-linked enzyme deficiency in male humans and congenital **hyperammonemia**. Crystal structures of *E. coli* and human enzymes are nearly isomorphous and contain a total of 14 α helices and 9 β strands organized into two domains.

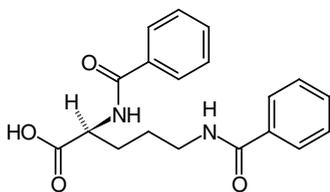

ornithine decarboxylase EC 4.1.1.17; *systematic name*: L-ornithine carboxy-lyase; an enzyme that catalyses the decarboxylation of L-ornithine to putrescine and CO_2 ; pyridoxal-phosphate is a coenzyme. It is the first enzyme of polyamine biosynthesis; its activity increases in response to many agonists, especially those stimulating cell growth. *See* **antizyme**.

ornithine transacetylase *see* **glutamate N-acetyltransferase**.

ornithine transporter 1 a member of the mitochondrial carrier family of transport proteins that reside in the inner mitochondrial membrane. The human protein (301 amino acids) consists of three homologous repeats, each of ≈ 100 residues and containing two transmembrane segments. Several mutations of ornithine transporter 1 are associated with the HHH syndrome (hyperammonemia, hyperornithinemia, and homocitrullinuria).

ornithine-urea cycle or **ornithine cycle** or **arginine-urea cycle** or **urea cycle** a cyclic metabolic pathway, present in mammals and other ureotelic animals, that converts waste nitrogen, in the form of highly toxic ammonium, to essentially nontoxic urea, which may then be excreted. Urea is formed by hydrolysis of L-arginine to L-ornithine, the cycle being completed by conversion of ornithine to L-citrulline by carbamoylation with carbamoyl phosphate (previously formed by enzymic combination of carbon dioxide and ammonium with phosphate from ATP), reaction of the citrulline with L-aspartate to form L-argininosuccinate, and cleavage of this to produce fumarate and regenerate arginine. Two enzymes of the cycle (carbamoylphosphate synthetase and ornithine carbamoyltransferase) reside in the mitochondrial matrix, the rest being cytosolic. Deficiency of any enzyme of the cycle leads to hyperammonemia. The cycle is also sometimes called the **Krebs urea cycle** or the **Krebs-Henseleit cycle**, after its discoverers. The role of argininosuccinate was revealed by the US biochemist, Sarah Ratner (1903–99), in 1954.

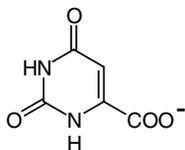

ornithuric acid *N,N'*-dibenzoylornithine; a detoxication product of benzoic acid found in the excreta of birds.

Oro symbol for a residue of the pyrimidine base orotate.

orosomucoid or α_1 -acid glycoprotein a ≈ 40 kDa, water-soluble plasma protein; it consists of a single polypeptide chain, with two intrachain disulfide bonds and carrying five branched, highly sialylated oligosaccharide units attached to the β -carboxyl groups of asparagine residues. Certain alleles of the gene encoding this protein have been found to be significantly increased in patients with different types of carcinoma.

orotate 1 symbol: Oro; uracil-6-carboxylate; 1,2,3,6-tetrahydro-2,6-dioxo-4-pyrimidine carboxylate; the anion of orotic acid (i.e. uracil-6-carboxylic acid). It is an intermediate in the biosynthesis of pyrimidine nucleotides from aspartate. **2** any mixture of orotic acid and its anion. **3** any salt or ester of orotic acid.

orotate phosphoribosyltransferase *abbr.*: OPRase; EC 2.4.2.10; *other names*: orotidylic acid phosphorylase; orotidine-5'-phosphate pyrophosphorylase; an enzyme of the pathway for *de novo* biosynthesis of pyrimidines. It catalyses the formation of orotidine 5'-phosphate from orotate and 5-phospho- α -D-ribose 1-diphosphate, releasing pyrophosphate. Orotidine 5'-phosphate is decarboxylated to uridine 5'-phosphate by **orotidine-5'-phosphate decarboxylase**. The human protein consists of 480 amino acids and contains domains for OPRase (residues 1–214) and orotidine 5'-phosphate decarboxylase (residues 221–480). Deficiency causes the recessive disease **orotic aciduria** type 1.

orotic aciduria a rare hereditary disorder of pyrimidine synthesis in humans that is characterized by retarded growth, hyperchromic anemia unresponsive to the usual hematinics, and an excessive excretion of orotate in the urine. It is due to deficiency of activity in the bifunctional **orotate phosphoribosyltransferase** (EC 2.4.2.10) and **orotidine-5'-phosphate decarboxylase** (EC 4.1.1.23), now called uridine 5'-monophosphate synthase. This protein is bicatalytic in mammals, but the two activities occur on separate proteins in prokaryotes and some eukaryotes. The condition results in the subject being a 'pyrimidine auxotroph' and can be effectively treated by administration of uracil, which both rectifies the pyrimidine deficiency and indirectly leads, through the effect of cytidine triphosphate on aspartate transcarbamoylase, to inhibition of orotate synthesis.

orotidine symbol: O or Ord; 6-carboxylatouridine; orotate riboside; 1- β -D-ribofuranosylorotate; a ribonucleoside occurring primarily as its 5'-phosphate, orotidylic acid but produced by certain mutants of *Neurospora crassa* and excreted in relatively large amounts in the urine of cancer patients treated with 6-azauridine. It is not known to be a component of ribonucleic acid.

orotidine monophosphate *abbr.*: OMP; *an alternative name for any orotidine phosphate*, but in particular for orotidine 5'-phosphate.

orotidine phosphate orotidine monophosphate (*abbr.*: OMP); any phosphoric monoester or diester of orotidine. Of the three possible monoesters – the 2'-phosphate, the 3'-phosphate, and the 5'-phosphate – and the two possible diesters – the 2',3'-phosphate and the

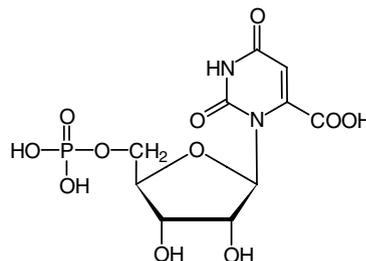

3',5'-phosphate – only **orotidine 5'-phosphate** is known to occur naturally (the locant therefore being omitted if no ambiguity may arise). **orotidine 5'-phosphate** or **5'-orotidylic acid** or **5'-phosphoorotidine** or **5'-O-phosphoorotidine** symbol: Ord5'P; *alternative recommended names for orotidine monophosphate* (*abbr.*: OMP), orotidine 5'-(dihydrogen phosphate), orotate ribonucleotide. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation.) It is the immediate biosynthetic precursor of uridine monophosphate, uridylic acid, UMP, to which it is converted by decarboxylation. Thus it is important also as an intermediate in the biosynthesis of other pyrimidine nucleotides from UMP.

orotidine-5'-phosphate decarboxylase EC 4.1.1.23; *other name*: orotidylic decarboxylase; an enzyme that catalyses the decarboxylation of orotidine 5'-phosphate to UMP a reaction carried out by the multifunctional enzyme **5'-monophosphate synthase**.

orotidine-5'-phosphate pyrophosphorylase *see* **orotate phosphoribosyltransferase**.

orotidylate 1 either the monoanion or the dianion of orotidylic acid. **2** any mixture of orotidylic acid and its anions. **3** any salt or ester of orotidylic acid.

orotidylic acid *the trivial name for any phosphoric monoester of orotidine*. The position of the phosphoric residue on the ribose moiety of a given ester may be specified by a prefixed locant – *see orotidine phosphate*. However, 5'-orotidylic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-Orotidylic acid is also an alternative recommended name for **orotidine 5'-phosphate**.

orotidylic acid phosphorylase *see* **orotate phosphoribosyltransferase**.

orotidylic decarboxylase *see* **orotidine-5'-phosphate decarboxylase**.

orphanin FQ or **nociceptin** an endogenous heptadecapeptide with an N-terminal phenylalanine and a C-terminal glutamine residue. It is derived from a precursor protein (186 amino acids) homologous to preprodynorphin and to preproenkephalin. It binds to a G-protein-coupled membrane receptor related to the opioid receptors. When injected into the cerebral ventricles of mice it produces hyperalgesia and inhibits locomotor activity.

orphan receptor a receptor whose physiological ligand is unknown.

ortho (*followed by to*) at a position in a benzene ring adjacent to a particular (specified) substituent.

ortho- *abbr.*: *o-*; *prefix (in chemical nomenclature) denoting an isomer of a disubstituted monocyclic aromatic compound in which the substituents are attached at positions 1 and 2 of the ring. Compare meta-, para-*.

ortho+ or (*before a vowel*) **orth+** *comb. form 1* straight or upright; perpendicular (to) or at a right angle (to); correct. **2 a** (*in inorganic chemistry*) denoting the most hydrated acid of a series of oxoacids formed from any one of certain anhydrides, or the anion or a salt formed from such an acid. The term is now approved only for orthoboric acid, H₃BO₃; orthosilicic acid, H₄SiO₄; orthophosphoric acid, H₃PO₄; orthoperiodic acid, H₅IO₆; and orthotelluric acid, H₆TeO₆. *Compare meta+* (def. 2), **pyro+**. **b** (*in organic chemistry*) similarly denoting hypothetical acids of general formula RC(OH)₃ or C(OH)₄ or real esters of such acids, e.g. trimethyl orthoacetate, CH₃-C(OCH₃)₃; tetramethyl orthocarbonate, C(OCH₃)₄.

ortho- and peri-fused describing a polycyclic compound in which

one ring contains two, and only two, atoms in common with each of two or more rings of a contiguous series of **ortho-fused** rings. Such compounds have n common faces and $<2n$ common atoms.

orthochromatic 1 (of a dye or stain) imparting, or capable of imparting, its own colour to a structure. **2** (of a structure) assuming, or capable of assuming, the same colour as that of a dye or stain with which it is treated. *Compare* **metachromatic**. —**orthochromatically** *adv.*

orthodox conformation the conformation adopted by a mitochondrion in the resting state when the [ATP]/[ADP] ratio is high. This is the usual conformation of mitochondria seen in electron micrographs of thin sections of intact tissue.

ortho-fused describing a polycyclic compound in which any two adjacent rings contain two, and only two, atoms in common. Such compounds have n common faces and $2n$ common atoms.

orthogonal 1 (of axes, lines, planes, surfaces, etc.) mutually at right angles; perpendicular to one another. **2** (*in statistics*) (of a set of variates) being, or regarded as being, statistically independent.

orthograde *see* **anterograde**.

orthologue or (*esp. US*) **ortholog** a gene, protein, or biopolymeric sequence that is evolutionarily related to another by descent from a common ancestor, having diverged as a result of a speciation event. Orthologues usually perform the same or highly similar functions in their different host species; e.g., human and bovine rhodopsins. —**orthologous** *adj.*

orthomyxovirus any of a group of RNA animal viruses, in class V of the **Baltimore classification**, consisting of enveloped, pleomorphic particles 80–120 nm in diameter. The nucleocapsids are helical, 6–9 nm in diameter, and of variable length, and contain segmented RNA (minus strand); this is transcribed by a virion polymerase into complementary RNA molecules, which act as messengers. The group includes the influenza A, B, and C viruses.

orthophosphate *an alternative name for phosphate* (used especially to distinguish from **metaphosphate** or **pyrophosphate**). *See also* **ortho+** (def. 2a).

orthostatic intolerance the combination of lightheadedness, fatigue, altered mentation, and fainting with postural tachycardia and excessive plasma norepinephrine concentration. The symptoms may be produced by cocaine, amphetamines, or tricyclic antidepressants, or by an autosomal dominant loss-of-function mutation in the **norepinephrine transporter**.

orthotopic transplant any tissue graft transplanted into the normal position of that tissue in the body of the recipient. *Compare* **heterotopic transplant**.

oryzain a group of proteases expressed during seed germination in rice. Three types (α , β , and γ) have been identified. γ -Oryzain (362 amino acids) is homologous with aleurain of barley, and with SAG (senescence-associated gene)-encoded cysteine proteases of *Ara-bidopsis*, maize, and *Brassica* species.

Os *symbol for osmium*.

osamine *an alternative name for aminodeoxysugar*.

osazone any 1,2-bis(arylhydrazono); i.e., any condensation product of the type $\text{RNH}-\text{N}=\text{CR}-\text{CR}'=\text{N}-\text{NHR}$ formed between an α -dicarbonyl compound (e.g., a 2-ketoaldehyde) and hydrazine, or a substituted hydrazine. α -Hydroxy- and α -amino-carbonyl compounds will also form osazones through oxidation of the corresponding [mono]hydrazones initially formed. *See also* **phenylosazone**.

oscillator an instrument or device for producing oscillations, especially an electronic device that produces an alternating output of known frequency.

oscillin a 33 kDa protein identified in sperm that induces oscillations in intracellular Ca^{2+} concentrations in mammalian eggs. It is considered to be involved in Ca^{2+} oscillations that serve as the essential trigger for egg activation and early development of the embryo.

oscillograph an instrument for producing a graphical record of an oscillating value.

oscilloscope an instrument for producing a temporary visual record of an oscillating value. A **cathode-ray oscilloscope**, based on the **cathode-ray tube**, provides a visual image of electrical signals, in the form of a graph of the signal over time.

OSCP *abbr. for oligomycin sensitivity-conferring protein*.

+ose *noun suffix 1* originally indicating related to glucose, as either an isomer (e.g. galactose) or a polymer (e.g. cellulose, maltose), now also extended to other sugars (e.g. arabinose, fructose, sucrose) or classes of sugars (e.g. aldose, furanose, ketose, hexose, pentose, pyranose). **2** indicating the primary products of hydrolysis of a biopolymer; e.g. proteose, peptose.

Ose (*in glycolipid nomenclature*) *symbol for a monosaccharide residue*. A numerical subscript denotes the number of connected monosaccharide units in the oligosaccharide component, and a prefix of two or three characters represents the trivial name of the oligosaccharide; e.g. GbOse₃ (i.e. globotriaose), nLcOse₄ (i.e. neolactotetraose), McOse₃Cer (i.e. mucotriosylceramide).

oside *an alternative term for glycoside*.

+oside *noun suffix* denoting **glycoside**.

+osis *noun suffix* denoting **1** a process or state (e.g. metamorphosis, narcosis, necrosis, osmosis). **2** a diseased condition (e.g. nephrosis, tuberculosis). **3** an increase or excess (of something) (e.g. glycogenesis, leukocytosis). *See also* **+otic**.

oskar one of the **maternal effect genes** in *Drosophila melanogaster*. It organizes the germplasm and directs localization of the germ-cell determinants. Oskar protein is required to keep *oskar* RNA and *staufer* (another maternal effect gene) protein at the posterior pole. Three other genes (*capu*, *spir*, and *stau*) are required for the initial localization of the *oskar* product to the posterior pole of the oocyte.

osM or **osm** *symbol for osmolal* (osmol L⁻¹ now recommended).

OSM *abbr. for oncostatin M*.

osmiophilic (of a structure or substance) having an affinity for, or staining readily with, osmium tetroxide; e.g. osmiophilic globules (plastoglobuli) in plastids.

osmium tetroxide osmium(VIII) oxide; OsO₄; a volatile, evil-smelling, moderately water-soluble, electron-dense substance used for fixing specimens for microscopy, especially electron microscopy, and used chemically in the hydroxylation of alkenes. The vapour is highly poisonous.

osmo+ *comb. form* denoting **1** osmosis. **2** smell, odour.

osmoceptor *see* **osmoreceptor**.

osmol *symbol for osmole*.

osmolal 1 describing a solution that contains one **osmole** (of a specified solute), or an indicated number of osmoles, per kilogram of solvent; used also of a specified solute in such a solution. **2** describing an amount-of-substance concentration expressed in osmoles (of a specified solute) per kilogram of solvent. *Compare* **osmolar**. *See also* **osmolality**.

osmolality the concentration of osmotically active particles in an aqueous solution expressed in **osmoles** per kilogram of solvent. For a nondissociating substance the osmolality is equal to the **molality**, whereas for a substance that dissociates in aqueous solution the osmolality is greater than the molality to an extent dependent on the number of particles into which the substance dissociates and on the position of the equilibrium. *Compare* **osmolarity**.

osmolar 1 describing a solution that contains one **osmole** (of a specified solute), or an indicated number of osmoles, per litre of solution; used also of a specified solute in such a solution. **2** *abbr.*: osM or osm; describing an amount-of-substance concentration expressed in osmoles (of a specified solute) per litre of solution. *Compare* **osmolal**. *See also* **osmolality**.

osmolarity the concentration of osmotically active particles in an aqueous solution expressed in **osmoles** per litre of solution. For a nondissociating substance the osmolarity is equal to the molarity, whereas for a substance that dissociates in aqueous solution the osmolarity is greater than the molarity to an extent dependent both on the number of particles into which the substance dissociates and on the position of the equilibrium. *Compare* **osmolality**.

osmole *symbol*: osmol; the amount of substance that contains, or gives rise to, one mole of osmotically active particles when in aqueous solution.

osmometer 1 or **membrane osmometer** any device for demonstrating the phenomena of osmosis and osmotic pressure; any instrument for measuring osmotic pressure. **2** an apparatus for measuring the acuteness of the sense of smell. —**osmometric** *adj.*; **osmometry** *n.*

osmophile any organism that grows preferentially (or only) in

media of relatively high osmotic pressure, such as ones with a high salt or sugar content. —**osmophilic** *adj.*

osmoreceptor or **osmoceptor** a sensory cell, or group of such cells, that is specialized to react to changes in environmental osmotic pressure, e.g. of blood plasma or of a tissue fluid. Osmoreceptors are located in the hypothalamus, in the main arteries, and at other sites.

osmoregulation the sum of the processes by which organisms regulate their internal contents of water and solutes. —**osmoregulatory** *adj.*

osmosis the spontaneous net flow of solvent by diffusion through a semipermeable membrane from a phase where the solvent has a higher chemical potential to one where the solvent has a lower chemical potential. The flow continues until the chemical potential of the solvent becomes the same on both sides of the membrane or until it is countered by a difference in hydrostatic pressure either generated or applied. —**osmotic** *adj.*; **osmotically** *adv.*; **osmose** *vb.*

osmotic coefficient *symbol:* ϕ_m (on a molality basis) or ϕ_x (on a mole fraction basis); the ratio of the actual to the ideal osmotic pressure of a given solution at a specified temperature; i.e. a representation of the departure of the solution from ideality.

osmotic pressure *symbol:* Π ; the excess hydrostatic pressure that must be applied to a solution in order to reduce to zero the net flow of pure solvent into it by osmosis. The osmotic pressure of a dilute solution is equal to the pressure the solute would exert if it could exist as a gas at the same temperature, T , and the same amount-of-substance concentration, c ; thus it may be expressed by a relation analogous to the gas equation, i.e. $\Pi = \nu cRT$ where ν is the (average) number of particles into which one solute molecule is dissociated under the given conditions, and R is the gas constant. Osmotic pressure is a **colligative property** of a solution. *See also* **colloid osmotic pressure**, **oncotic pressure**.

osmotic shock any disruption or other disturbance caused to suspended cells or cell organelles by a sudden change in the osmotic pressure of their suspending medium.

osmotin a basic protein abundant in tobacco cells grown in a salt-rich medium. The 26 kDa mature protein accumulates in the cell vacuole in response to biotic stimuli (i.e. phytohormones, viral or fungal infection) and abiotic stimuli (i.e. water deprivation, cold, UV irradiation, wounding).

osmotolerant describing a cell or organism that is tolerant to a wide range of osmotic pressures in its environment.

osone any 2-ketoaldose; use not recommended.

ossein the organic material, consisting mainly of collagen, that remains after treatment of bone with dilute acid to dissolve out the inorganic components.

ossify to make into bone or to become bone. —**ossification** *n.*

osteo+ or (before a vowel) **oste+** or (sometimes) **ost+** *comb. form* denoting bone.

osteoblast a mesenchymal cell that secretes the organic matrix of bone (i.e. osteoid, consisting chiefly of collagen); as the matrix becomes calcified the osteoblast becomes trapped and is known as an osteocyte.

osteocalcin *other names:* γ -carboxyglutamic acid-containing protein; bone GLA-protein (*abbr.:* BGP); a protein that binds Ca^{2+} and apatite; the binding depends on γ -carboxyglutamic acid residues (three per molecule) formed by vitamin K-dependent carboxylation.

osteochondrodysplasia a very heterogeneous disorder of skeletal development that is frequently associated with dwarfism, spinal deformity, and joint abnormalities. There are numerous forms, of which many arise from mutations in collagen types II, IX, X, and XI; in receptors for somatotropin and fibroblast growth factors; or in sulfate transport protein.

osteochondromatosis *an alternative name for* **hereditary multiple exostoses**.

osteoclast a large, multinucleate **macrophage** that erodes bone matrix and is able to tunnel deep into the substance of compact bone. Osteoclasts are formed by the fusion of blood monocytes and play an important role in the remodelling of bone and the removal of dead bone.

osteocyte an osteoblast when it has become trapped in a lacuna of

the bone matrix and is no longer able to divide or secrete appreciable amounts of new matrix. Osteocytes are connected by fine cellular processes that pass through the bone canaliculi.

osteogenesis the processes of bone formation; ossification.

osteogenesis imperfecta or '**blue eyes-broken bones disease**' or **brittle bone disease** a genetically heterogeneous group of human diseases distinguished by the severity of bone fragility, scleral coloration, hearing loss, abnormal dentition, and soft-tissue dysplasia involved. Four autosomal dominant phenotypes are recognized: type 1 (mild) has blue sclerae and bone fragility; type 2 (prenatal lethal) has dark sclerae, severe bone fragility, and bone deformity; type 3 (deforming) has light sclerae, bone fragility, progressive deformity, imperfect dentition, and short stature; type 4 (mild deforming) has light sclerae, imperfect dentition, and mild short stature. Over 200 mutations in type I collagen genes are responsible. Those that abolish synthesis of pro- α -1 (I) or pro- α -2 (I) can produce most phenotypes, while splice junctions in either gene produce different phenotypes depending on their position. Partial deletions in either gene usually result in type 4.

osteoid 1 the unmineralized bone matrix secreted by osteoblasts; it consists chiefly of collagen. **2** resembling bone.

osteolysis the breakdown and dissolution of bone, especially through disease. —**osteolytic** *adj.*

osteomalacia a clinical condition of adults characterized by softening and deformation of the bones due to a failure to maintain their mineralization. It has a wide variety of possible causes, of which dietary deficiencies of vitamin D, calcium, or phosphate are the commonest.

osteonectin *see* SPARC.

osteoporosis or **osteosclerosis** or **marble bone disease** a rare, heterogeneous disorder in which there is decreased osteoclastic resorption of bone and widespread expansion of bone mass. *Compare* **osteoporosis**.

osteopontin *other names:* bone sialoprotein 1; urinary stone protein; secreted phosphoprotein 1 (*abbr.:* SPP-1); nephropontin; uropontin; a bone-specific sialoprotein produced by cells in osteoid matrix, but independently discovered from several different functions. It can form a bridge between cells and the mineral in the matrix, and is found at high concentrations on the cement lines, where bone formation follows resorption. It is also found in the kidney, and plays a major role in urinary stone formation. In arterial smooth muscle cells, its level increases in atherosclerotic plaques. It is secreted, binds calcium, and binds covalently to fibronectin. It has an **RGD** integrin-binding sequence, and is one of the major ligands for the vitronectin receptor. It is phosphorylated on serine, and is an *O*- and *N*-glycosylated protein. There are four forms from alternative splicing.

osteoporosis a condition characterized by a general or local reduction in bone mass with little alteration in gross composition. This causes the affected bones to become porous, brittle, and liable to fracture. Recognized forms include: (1) postmenopausal; (2) senile; (3) secondary – to other conditions or to drugs (e.g. corticosteroids, barbiturates, anticonvulsants), chronic alcoholism, and cigarette smoking; (4) idiopathic juvenile. *Compare* **osteopetrosis**.

osteoprotegerin or **osteogenic inhibitory factor** (*abbr.:* OCIF) a protein belonging to the tumour necrosis factor (TNF) superfamily that is present on, or secreted by, osteoblasts. It binds **RANK** and prevents this from binding to **RANK** on osteoclasts, thereby preventing bone resorption. Overexpression of osteoprotegerin in mice leads to **osteopetrosis**, with excessive calcification of bone.

osteostatin a polypeptide that consists of residues 107–139 of **parathyroid hormone-related protein**. It has effects on bone resorption and on brain, although its physiological role is unclear.

Ostwald dilution law a relationship, deduced in 1888 by the Russian-born German chemist Friedrich Wilhelm Ostwald (1853–1932), between the amount-of-substance concentration, c , and the degree of dissociation, α , of a weak electrolyte. It is given by:

$$\alpha^2 c / (1 - \alpha) = K,$$

where K is the apparent dissociation constant of the electrolyte.

Ostwald pipette a pipette for measuring small volumes of liquids, especially viscous liquids. It features a capillary stem and delivery

jet and a shoulderless bulb near the jet. Various modifications have been described.

Ostwald viscometer a simple **capillary viscometer**.

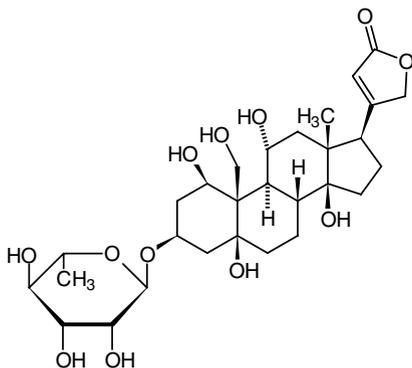

+osyl *suffix* indicating a **glycosyl** group.

+otic *suffix forming adjectives and nouns* **1** affected by (e.g. necrotic) or relating to (e.g. osmotic). **2** causing (e.g. mitotic, narcotic). — **+otically** *adv.*

otoferlin a protein that is homologous with spermatogenesis factor (fer-1) of *Caenorhabditis elegans*, and is related to dysferlin and myoferlin of humans. It consists of 1977 amino acids, with a transmembrane segment close to the C-terminus, the rest being intracellular. Several mutations cause an isolated profound deafness.

otogelin the product of a candidate gene for an autosomal recessive form of deafness. It is predicted to be a secreted glycoprotein (2910 amino acids) that, like α -tectorin, is specific to acellular membranes of the inner ear. It consists of a central region that is rich in threonine, serine, and proline residues, flanked on the N-terminal side by four vWF domains, and on the C-terminal side by several vWF-like domains.

ouabain or **G-strophanthin** a **cardiac glycoside** whose carbohydrate moiety is L-rhamnose, obtained from the seeds of *Strophanthus gratus*. It is a specific inhibitor of the membrane-bound sodium pump Na^+, K^+ -ATPase (*see* **sodium/potassium ATPase**) of animal cells.

Ouchterlony technique a development of **double immunodiffusion**, effected in two dimensions so that comparisons can be made between two or more antigen-containing samples in their reaction with one antiserum. The particular pattern of precipitation lines or arcs formed enables conclusions to be drawn regarding the identity, partial identity, or nonidentity of antigens in the various samples examined. [After O. Ouchterlony, French immunologist.]

Oudin technique a simple, single immunodiffusion technique, effected in one dimension, in which a solution of an antigen-containing sample is placed above a column of antiserum incorporated in a gel in a tube; antigen diffuses into the gel, where it reacts with antibody to form one or more precipitation bands. [After Jacques Oudin (1923–).]

ounce *symbol:* oz; a unit of mass, equal in the avoirdupois system to one-sixteenth of a pound (= 28.3495 grams). This must be distinguished from the **troy ounce** (equal to 480 grains, 31.1035 grams).

outer membrane 1 (*in eukaryotes*) the more external of the two membranes that surround a chloroplast, a mitochondrion, or a nucleus. **2** (*in prokaryotes*) the layer of lipopolysaccharide, lipoprotein, and protein that lies external to the peptidoglycan in the cell wall of a Gram-negative bacterium.

outer membrane protein P68 *see* **peractin**.

outlier (*in statistics*) a data point that falls far outside the values of others in a data set. The nature of outliers should be understood prior to further analysis: those arising from measurement errors will distort the statistics and hence interpretation of the data; those that are genuine, however, may point to unexpected and hence highly interesting results.

ov+ a variant form of **ovi+** (before a vowel).

ova the plural of **ovum**.

ovalbumin *abbr.:* OA; a =44.5 kDa glycoprotein, also called egg al-

bumin, that is the major protein of egg white from hens' eggs. Each molecule consists of a single polypeptide chain, and carries a single oligosaccharide chain containing only mannose and *N*-acetylglucosamine residues. It is included in the **serpin** family. It is synthesized by the oviduct under hormonal control. Although a secreted protein, it has no N-terminal signal peptide.

ovalocytosis an abnormality of erythrocytes that makes them oval or elliptical rather than circular. Southeast-Asian ovalocytosis, which is common in Melanesia, Indonesia, Papua New Guinea, and Philippines, is caused by mutations in band 3 protein (*see* **band protein**).

ovarian hormone any of the numerous steroid hormones secreted by the ovary.

ovary 1 (*in zoology*) the gonad of a female animal; vertebrates have a pair of ovaries. The ovary contains oocytes from which ova are produced, and it also secretes various steroid hormones. Its activity is cyclical and is controlled by gonadotropin(s). **2** (*in botany*) the enlarged basal part of a carpel or a syncarpous gynecium of a flower that contains one or more ovules. — **ovarian** *adj.*

overgrowth 1 excessive growth; hyperplasia. **2** a later but more vigorous growth by another strain or species of organism that supplants one already existing.

Overhauser effect or **Overhauser enhancement** *see* **nuclear Overhauser effect**.

overlap peptide a fragment, produced by partial hydrolysis of a polypeptide or protein, that contains both the C-terminal part of the sequence of another peptide fragment and the N-terminal part of a further fragment, allowing those two to be placed in the correct position in the overall sequence of the parent compound during protein sequencing procedures.

overlapping code a code in which one element of a code-word forms part of an adjacent code-word in an encoded piece of information. A triplet code (such as the **genetic code**, where the code-words are codons) may be either: a **fully overlapping code**, in which one code-word consists of the elements at positions n , $(n+1)$, $(n+2)$, and the next code-word consists of the elements at positions $(n+1)$, $(n+2)$, $(n+3)$; or a **partially overlapping code**, in which adjacent code-words comprise elements at n , $(n+1)$, $(n+2)$, and those at $(n+2)$, $(n+3)$, $(n+4)$. In a **nonoverlapping code**, such as the genetic code proved to be, no element of one code-word forms part of an adjacent code-word.

overlapping gene any gene whose polynucleotide sequence overlaps, wholly or in part, that of another gene in the same stretch of a genome. The codons may or may not be in the same **reading frame**. In mitochondria and some viruses, some mRNAs are synthesized by the transcription of the same DNA using different reading frames.

overpressure(d) layer chromatography *abbr.:* OPLC; a chromatographic technique that gives some of the advantages of **high-pressure liquid chromatography** to **thin-layer chromatography**, with resultant increases in both speed and efficiency of separation. The sorbent layer is completely covered by a flexible membrane under external pressure and the solvent is pumped continuously through the sorbent layer.

overshoot the extent to which a control system causes the variable being controlled to go initially beyond its final equilibrium position.

ovi+ or **ovo+** or (*before a vowel*) **ov+** *comb. form* denoting ovum or egg.

oviduct (*in zoology*) the tube through which ova are conveyed from the ovary to the exterior or to some intermediate organ such as the uterus. In mammals it is known more commonly as the **Fallopian tube** or **uterine tube**.

oviductin *other name:* gp43 processing protease; a high molecular weight glycoprotein that is secreted by the non-ciliated secretory cells of the oviduct, and later transferred to the zona pellucida of the oocyte during oviductal transit. It processes a 43 kDa glycoprotein of the oocyte envelope during its transit through the duct.

ovine *abbr.:* o or (*formerly*) O; of, belonging to, characteristic of, obtained from, or being sheep or a sheep; resembling a sheep, sheeplike.

ovo+ a variant form of **ovi+**.

ovoflavin or **oviflavine** a former name for **riboflavin**.

ovoinhibitor a contaminant of crude **ovomucoid** that, unlike pure ovomucoid, inhibits chymotrypsin as well as trypsin.

ovomucoid a glycoprotein found in egg white from hens' eggs; it is an inhibitor of trypsin.

ovothiol a novel thiohistidine compound from sea-urchin eggs that confers NAD(P)H-O₂ oxidoreductase activity on ovoperoxidase.

ovotransferrin *an alternative name for conalbumin.*

ovulate to discharge an egg or eggs from an ovary. —**ovulation** *n.*

ovule 1 (*in botany*) a structure in the ovary of a seed plant that develops into a seed after fertilization of the egg cell within it. **2** (*in zoology*) a small, especially immature, ovum or egg.

ovum (*pl. ova*) (*in zoology*) strictly, an unfertilized egg cell, i.e. female gamete, which contains a haploid nucleus and which on fertilization has the unique ability to develop into a new individual. In many animals, mammals included, **oogenesis** is arrested and meiosis is not completed until after fertilization of the secondary **oocyte**, hence in these animals an ovum in the strict sense cannot exist. However, the term is often applied instead either to the secondary oocyte or to the product resulting from the second meiotic division after fertilization.

oxa+ or (*sometimes before a vowel*) **ox+** prefix (*in chemical nomenclature*) denoting replacement of a methylene group in a specified acyclic or monocyclic hydrocarbon by an oxygen atom. For certain natural products, (e.g. tetrapyrroles), the meaning is extended to denote replacement of a noncarbon atom (with any attached hydrogen atoms) by an oxygen atom.

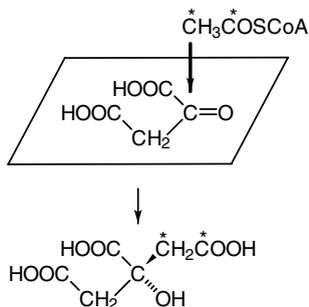

oxalacetate *an alternative name for oxaloacetate.*

oxalate 1 the trivial name for ethanedioate, ⁻OOC-COO⁻, the dianion of oxalic acid, i.e. ethanedioic acid. It occurs in many plants, especially sorrels of the genera *Oxalis* and *Rumex*, and is highly toxic to animals. Normally, small amounts are formed in humans and excreted in the urine; larger amounts occur in patients with **hyperoxaluria**. The calcium salt is virtually insoluble in water, a property that is valuable in the determination of calcium and in the use of oxalate *in vitro* as an anticoagulant. **2** any mixture of free oxalic acid and its mono-ions and dianions. **3** any salt or ester of oxalic acid.

oxalo the univalent acyl group, HOOC-CO-, derived from oxalic acid by loss of one hydroxyl group. *See also oxalyl* (def. 1).

oxalo+ prefix indicating the presence of an oxalo group.

oxaloacetate or (*rarely*) **oxalacetate** *abbr.:* OAA; **1** the trivial name for oxosuccinate (*formerly* ketosuccinate); oxobutanedioate; ⁻ooC-CO-CH₂-COO⁻ (keto form) or ⁻ooC-c(OH)=CH-COO⁻ (enol form); the dianion of oxaloacetic acid. It is an important intermediate in metabolism, especially as a component of the **tricarboxylic-acid cycle**. The stereochemistry of the **citrate (5 β)-synthase** reaction is shown below. **2** any mixture of free oxaloacetic acid and its mono- and dianions. **3** any salt or ester of oxaloacetic acid.

oxalosis the renal and extrarenal deposition of calcium oxalate (*see oxalate*) seen in patients with **hyperoxaluria**.

oxalosuccinate 1 the trivial name for 2-oxotricarballylate (*formerly* α -ketotricarballylate); 1-oxopropane-1,2,3-tricarboxylate; ⁻OOC-CO-CH(COO⁻)-CH₂-COO⁻; the trianion of oxalosuccinic acid. It is an enzyme-bound intermediate in the conversion of isocitrate to 2-oxoglutarate by **isocitrate dehydrogenase (NAD⁺)** in the **tricarboxylic-acid cycle**. **2** any mixture of free oxalosuccinic acid and its mono- and dianions. **3** any salt or ester of oxalosuccinic acid.

oxaluria *an alternative name for hyperoxaluria.*

oxalyl 1 (*in biochemistry*) (*sometimes*) *an alternative name for oxalo.* **2** (*in chemistry*) the divalent diacyl group, -CO-CO-, derived from oxalic acid by loss of both hydroxyl groups.

OXBOX a 13 bp sequence (present in the region -123 to -674 bp) of the heart and skeletal muscle gene for the adenine nucleotide translocator and also in the promoter region of the gene for human ATP synthase β subunit. It appears to be a positive translational element.

oxene a reactive species of oxygen involved in the hydroxylation reaction catalysed by cytochrome P450; it is iron-bound oxygen which is electron deficient but electrically neutral -P450-Fe³⁺-O. It reacts with the bound substrate to release the hydroxylated substrate with the regeneration of P450-Fe³⁺.

oxidant the chemical species that accepts one or more electrons in a redox reaction; i.e. the species that undergoes reduction in such a reaction. *Compare reductant.*

oxidase any **oxidoreductase** that catalyses a reaction in which dioxygen is the electron acceptor (i.e. **oxidant**).

oxidase test a test for the presence of cytochrome *c* oxidase in bacteria that depends on the oxidation of tetramethyl-*p*-phenylenediamine to a violet-coloured product. It is useful for primary characterization, especially of Gram-negative organisms.

oxidation 1 the action or process of reacting with oxygen, especially the addition of oxygen to a substance. **2** the loss or removal of hydrogen from a substance. **3** the loss or removal of one or more electrons from a molecular entity, with or without concomitant loss or removal of a proton or protons. In this sense, oxidation is the opposite of, and is always coupled to, **reduction**. **4** the increase to a more positive value of the **oxidation number** of an atom, whether the atom is uncharged or charged, and whether free or covalently bound. —**oxidative** *adj.*

α -**oxidation** *see alpha-oxidation.*

β -**oxidation** *see beta-oxidation.*

ω -**oxidation** *see omega-oxidation.*

oxidation level or **oxidation state** the status of an organic compound in terms of whether it can be considered to undergo oxidation or reduction (or neither) upon conversion to a related compound. If conversion involves oxidation, the parent compound is said to have a higher oxidation level than the product; if conversion involves reduction, the parent compound is said to have a lower oxidation level. The term is thus used in a relative rather than an absolute sense. *See also oxidation number.*

oxidation number or **oxidation state** a number assigned to a particular atom in a molecular entity that represents, actually or notionally, the charge on that atom. Thus, atoms of pure elements have an oxidation number of zero; in molecules of simple electrovalent compounds the oxidation number of each component atom is equal to the charge on the respective ion; and in molecules of covalent compounds the notional charge on a particular atom is derived by assigning electrons to the more electronegative partner in each bond involving the atom in question. By convention, hydrogen is considered to have an oxidation number of +1 when in combination with nonmetals. The oxidation number of a carbon atom can range from -4 (e.g. in CH₄) through zero (e.g. in CH₂O or solid C) to +4 (e.g. in CO₂). The oxidation number of an atom may be indicated by a Roman numeral; e.g. iron(III) oxide, ferric oxide, Fe₂O₃. The algebraic sum of the oxidation numbers of all the atoms in any molecular entity must equal the charge on that entity.

oxidation potential a measure of the tendency of a substance to oxidize spontaneously through loss of electrons. It is the standard potential of the half-reaction: A → Aⁿ⁺ + *ne* and is equal to the **reduction potential** but of opposite sign.

oxidation-reduction *an alternative term for redox.*

oxidation-reduction indicator *an alternative term for redox indicator.*

oxidation-reduction potential *an alternative term for redox potential.*

oxidation state 1 *an alternative term for oxidation number.* **2** *an alternative term for oxidation level* (less preferred).

oxidative deamination deamination with concomitant oxidation, as in the enzymic conversion, regardless of the nature of the elec-

tron acceptor, of an α -amino acid to an α -oxo acid. *Compare reductive amination.*

oxidative decarboxylation decarboxylation with concomitant oxidation, as in the enzymic conversion, regardless of the nature of the electron acceptor, of an α -oxo acid (actually or formally) to a carboxylic acid containing one less carbon atom.

oxidative metabolism *an alternative term for respiration* (def. 1).

oxidative pentose phosphate pathway or **hexose monophosphate shunt** a route additional to glycolysis in plants that generates: (1) NADPH when it is not being formed by photosynthesis; (2) ribose 5-phosphate required in the biosynthesis of nucleosides; and (3) erythrose 4-phosphate required for biosynthesis of shikimic acid, a key intermediate in the formation of aromatic rings. *See also pentose phosphate pathway.*

oxidative phosphorylation or **respiratory-chain phosphorylation** the phosphorylation of ADP to ATP that accompanies the oxidation of a metabolite through the operation of the **respiratory chain**. The overall reaction may be summarized by the equation:

where AH_2 is an oxidizable metabolite, A is the product of the oxidation, P_i is inorganic orthophosphate, and x has a value between 1 and 3 depending on the nature of AH_2 and the functional state of the respiratory chain. The proton gradient built up across the inner mitochondrial membrane by the proton pumps of the respiratory chain drives ATP synthesis by the **H⁺-transporting ATP synthase**. *See also chemiosmotic coupling hypothesis.*

oxidative stress a state of metabolic imbalance within cells that favours pro-oxidant substances (e.g. superoxide, hydrogen peroxide, hypochlorous acid, nitric oxide, peroxydinitrite) rather than antioxidants (e.g. glutathione, ascorbic acid) and antioxidant enzyme systems (e.g. superoxide dismutases, catalase). This leads to oxidative damage to all classes of the major biomolecules. Depending on the degree of imbalance, a cell may die or it might survive in a changed state. Such stress can be important in causing a wide variety of degenerative states, including atherosclerosis, ischemia/reperfusion injury in heart and brain, mutagenesis, and chronic inflammatory disease.

oxide 1 (*in inorganic chemistry*) any binary compound of oxygen and some other element. **2** *an alternative generic name for any cyclic ether that is an oxirane*; such a compound is named as the oxide of the alkene from which it may be formed through addition of an atom of oxygen across the double bond; e.g. ethylene oxide, $\text{C}_2\text{H}_4\text{O}$. **3** *a term used in some languages for ether*. **4** any compound in which an oxygen atom has been attached to a heteroatom of a precursor compound. This definition includes compounds of general formulae: $\text{RC}\equiv\text{NO}$ (nitrile oxides; e.g. benzonitrile oxide), $>\text{C}=\text{N}(\text{O})\text{R}$ or $\text{R,R}',\text{R}''\text{NO}$ (*N*-oxides, amine oxides; e.g. trimethylamine oxide); and $\text{R,R}'\text{SO}$ (*S*-oxides, sulfoxides; e.g. methionine *S*-oxide; dimethyl sulfoxide).

+oxide or **+olate** *suffix denoting 1* an anion formed by loss of a proton from the hydroxyl group of an alcohol or phenol; e.g. ethoxide ion, $\text{C}_2\text{H}_5\text{O}^-$. **2** a compound of such an anion with a cation; e.g. sodium phenoxide (i.e. sodium phenolate), $\text{C}_6\text{H}_5\text{ONa}$. *See also epoxide, hydroperoxide, hydroxide, nitroxide, peroxide, sulfoxide, superoxide.*

oxidize or **oxidise 1** to undergo or effect **oxidation**. **2** to form or cause to form a superficial layer of oxide on a metal. *Compare reduce. —oxidization or oxidisation n.*

oxidizer or **oxidiser 1** *a less common name for oxidizing agent*. **2** a device for effecting a particular oxidation.

oxidizing agent or **oxidising agent** any substance or mixture used for effecting **oxidation**.

oxidoreductase *the systematic name for any enzyme of class EC 1*. These enzymes catalyse oxidation–reduction (i.e. **redox**) reactions and the class comprises **dehydrogenases**, **oxidases**, and **reductases**.

oxidoreduction *an alternative term for redox*.

oximeter any photometric device for (continuously) measuring the oxyhemoglobin/hemoglobin ratio in blood, either *in vivo* or *in vitro*.

oxine *the trivial name for 8-hydroxyquinoline*; 8-quinoline. With many species of metal ion this compound forms water-insoluble

chelate complexes and thereby is useful in analysis. It is also a disinfectant, and, as the copper chelate, is an effective fungicide.

oxirane 1 *the class name for any compound containing a three-membered saturated ring comprising two carbon atoms and one oxygen atom*. **2** *the systematic name for the type member of this class, known commonly as ethylene oxide, $\text{C}_2\text{H}_4\text{O}$* .

oxo 1 the chemical group consisting of an oxygen atom, =O, doubly bonded to another atom (often of carbon) in a molecular structure. When bonded to a carbon atom it forms the carbonyl group, $>\text{C}=\text{O}$. *Compare oxy. 2 or (formerly) oxo+* modifying the class-name of a chemical compound to indicate the presence of an oxo group as a substituent in place of two hydrogen atoms; e.g. **oxocarboxylic acid**. The position of substitution may be specified by a prefixed locant; e.g. 17-oxo-steroid. *See also keto* (def. 3). *Compare oxo* (def. 1).

oxo+ or (*sometimes before a vowel*) **ox+** **1 prefix** (*in chemical nomenclature*) indicating substitution of a doubly bonded oxygen atom into a specified compound or group by the (formal or actual) oxidation of a methylene group, $>\text{CH}_2$, to a keto group, $>\text{C}=\text{O}$, or of a methyl group, $-\text{CH}_3$, to a formyl group, $-\text{CH}=\text{O}$, with the production of a ketone or an aldehyde respectively; e.g. oxoglutaric acid (*see oxoglutarate*), 3,6-dioxohexanoic acid (or 5-formyl-3-oxopentanoic acid). *Compare oxo* (def. 2). **2 comb. form** denoting presence of one or more (singly or doubly bonded) oxygen atoms in a molecular structure; e.g. **oxoacid**, **oxonium**.

oxoacid 1 *the recommended term for any compound whose molecular structure contains oxygen, at least one other element, and at least one atom of hydrogen bound to oxygen, and also that yields a conjugate base (see oxoanion) by loss of a hydron*. Examples include: hypochlorous acid, ClOH ; sulfurous acid, $\text{O}=\text{S}(\text{OH})_2$; nitric acid, $\text{O}=\text{NOH}$; [ortho]phosphoric acid, $\text{O}=\text{P}(\text{OH})_3$; and also any phosphonic acid, $\text{RP}(\text{=O})(\text{OH})_2$, and any carboxylic acid, $\text{RC}(\text{=O})\text{OH}$ (where $\text{R} = \text{H}$ or hydrocarbyl). *See also oxocarboxylic acid. 2 or oxo acid or oxyacid or oxy-acid the traditional name, now obsolete, for any acid having oxygen in its acidic function, as opposed to a 'hydracid' where oxygen is lacking (e.g. hydrochloric acid, HCl).*

oxo acid 1 *see oxocarboxylic acid. 2 a variant of oxoacid* (def. 2).

3-oxoacid CoA-transferase EC 2.8.3.5; *other name*: succinyl-CoA:3-ketoacid-CoA transferase; an enzyme that catalyses the reaction:

In mammals it converts plasma acetoacetate that has been taken up by tissues into acetoacetyl-CoA for further metabolism.

3-oxoacyl-[acyl-carrier protein] reductase (NADH) EC 1.1.1.212; an enzyme that catalyses the reduction by NADH of 3-oxoacyl-[acyl-carrier protein] to (3R)-3-hydroxyacyl-[acyl-carrier protein] with formation of NAD^+ . This is one of the steps of fatty acid synthesis in plants. *Compare fatty acid synthase complex.*

oxoanion or (*formerly*) **oxo anion** or **oxyanion** or **oxy-anion** any of the possible anions formable from a molecule of an **oxoacid** (def. 1) by loss of one or more hydrons.

oxobutanedioate *see oxaloacetate*.

oxocarboxylic acid *the recommended name for any carboxylic acid that contains an aldehydic group attached to, or/and one or more ketonic groups contained in, its principal chain or parent ring system, i.e. any into which one or more oxo groups have been substituted*. The term is commonly shortened to **oxo acid**, but the full name should be used wherever confusion with **oxoacid** is possible. The older term keto acid is often still used (*see keto* (def. 3)).

17-oxogenic steroid or (*formerly*) **17-ketogenic steroid** any urinary corticosteroid or its metabolites that can be estimated by the **Zimmermann reaction** after oxidation to the corresponding 17-oxo steroid.

oxoglutarate or (*formerly*) **ketoglutarate**; **1** 2-oxoglutarate or α -oxoglutarate 2-oxopentanedioate; $^-\text{OOC}-[\text{CH}_2]_2-\text{CO}-\text{COO}^-$; the dianion of 2-oxoglutaric acid (i.e. 2-oxopentanedioic acid), an α -oxo (carboxylic) acid. It is a key constituent of the tricarboxylic-acid cycle and a key intermediate in amino-acid metabolism. In the cycle it is formed by oxidative decarboxylation of isocitrate and converted into a further oxidative decarboxylation reaction to succinyl-coenzyme A. It may also be formed from or converted into gluta-

mate (and thus several other amino acids indirectly) by transamination, or formed by degradation of lysine via glutarate and 2-hydroxyglutarate. The older name **α -ketoglutarate** is often still used. **2** 3-oxoglutarate or **β -oxoglutarate** acetonedicarboxylate; 3-oxopentanedioate; $^{-}\text{OOC}-\text{CH}_2-\text{CO}-\text{CH}_2-\text{COO}^{-}$; the dianion of 3-oxoglutaric acid (i.e. 3-oxopentanedioic acid), a **β -oxo** (carboxylic) acid. It is a product of the action of the mould *Aspergillus niger* on citrate.

oxoglutarate decarboxylase *see* **oxoglutarate dehydrogenase (lipoamide)**.

oxoglutarate dehydrogenase complex an enzyme complex, closely analogous in mechanism to the **pyruvate dehydrogenase complex**. It accomplishes the overall reaction:

It consists of three activities: **oxoglutarate dehydrogenase (lipoamide)**, the E₁ component; **dihydrolipoamide S-succinyltransferase**, the E₂ component; and **dihydrolipoamide dehydrogenase**, the E₃ component (this being identical to the E₃ component of the pyruvate dehydrogenase complex).

oxoglutarate dehydrogenase (lipoamide) EC 1.2.4.2; *other names*: oxoglutarate decarboxylase; α -ketoglutaric dehydrogenase; an enzyme that catalyses the reaction between 2-oxoglutarate and lipoamide to form S-succinyl-dihydrolipoamide with release of CO₂. This is the E₁ component of the **oxoglutarate dehydrogenase complex**. Thiamine diphosphate is a coenzyme.

oxoglutarate/malate carrier protein *see* **OGCP**.

2-oxoisovalerate dehydrogenase *see* **3-methyl-2-oxobutanoate dehydrogenase (lipoamide)**.

oxolinic acid 5-ethyl-5,8-dihydro-8-oxo-1,3-dioxolo[4,5-g]quinoline-7-carboxylic acid; a **4-quinolone antibiotic** with antibacterial activity through inhibition of bacterial DNA gyrase.

oxonium 1 or (formerly) **hydronium** or **hydroxonium** the ion, H₃O⁺, formed by covalent linkage of a hydron to a single water molecule. *Compare* **H⁺(aq)**. **2** any organic entity in which an oxygen atom is linked to three groups (one or two of which may be -H) and bears a formal single positive charge.

5-oxoprolinase an enzyme of microorganisms, plants, and most mammalian tissues that catalyses the reaction:

A rare enzyme deficiency in humans produces excessive 5-oxoprolinuria but no other significant symptoms or signs.

(5)-oxoproline *symbol*: Glp or <Glu; *the recommended trivial name* for pyroglutamic acid; pyrrolidone carboxylic acid; 5-oxopyrrolidine-2-carboxylic acid; a **noncoded amino acid**. It occurs at the N terminus of certain peptide hormones, and is an intermediate in the γ -glutamyl cycle. *Compare* **oxyproline**.

oxo steroid or **keto steroid** any steroid having an oxo substituent in its molecular structure, whether in the ring system (as part of a ketonic group) or in a side chain (as part of either a ketonic or an aldehydic group). The position of substitution may be specified by a prefixed locant. The term **17-oxo steroid** (or 17-keto steroid) usually refers specifically to any of a group of androgens and their metabolites that are present in urine and that can be extracted and estimated by the **Zimmermann reaction**. The amount of steroids excreted in the urine has been used as an index of androgen production in the body.

oxosuccinate *see* **oxaloacetate**.

oxphos a colloquial term for **oxidative phosphorylation**.

OXT *abbr.* for oxytocin.

oxy the chemical group consisting of an oxygen atom, -O-, singly bonded to two carbon atoms in a molecular structure, e.g. of an epoxide, an ester, or an ether. *Compare* **oxo**.

oxy+ *prefix* denoting **1** (in *organic chemical nomenclature*) the presence of an oxygen atom directly attached (by single covalent bonds) to two moieties of the same indicated parent compound, with formation of a symmetrical ether, where there is a functional group or substituent in the parent compound that has priority over 'ether' for citation as the principal characteristic group; e.g. 3,3'-oxydipropionic acid (not bis(3-carboxypropyl) ether). *See also* **epoxy+**. **2** (obsolete in *organic chemical nomenclature* but retained in *pharma-*

ceutical nomenclature) substitution of a hydroxyl group for a hydroxyl atom; e.g. oxyproline (now hydroxyproline), oxytetracycline. **3** (in *inorganic chemical nomenclature*) formation of a 'basic' (i.e. double) salt containing the oxide anion, O²⁻, and a specified second anion; e.g. bismuth oxychloride (i.e. bismuth chloride oxide). **4** or **oxy-** presence of oxygen in the acidic function of an acid or in the corresponding moiety of a derived anion (obsolete; *see* **oxoacid** (def. 2), **oxoanion**). *comb. form* indicating. **5** dioxygen; e.g. oxybiotic, oxyhemoglobin, oxyhydrogen. **6** oxidation; e.g. oxycellulose. **7** acid; e.g. **oxyntic**.

oxyacid or **oxy-acid** a variant of **oxoacid** (def. 2).

oxyanion or **oxy-anion** (formerly) a variant of **oxoanion**.

oxybiontic or **oxybiotic** living in the presence of oxygen; aerobic.

oxycellulose any of the various materials obtained by the oxidation of cellulose. Such materials are useful as cation-exchangers or for fabrication into lint and gauzes.

oxygen 1 *symbol*: O; a nonmetallic element of group 16 of the (IUPAC) **periodic table**; atomic number 8; relative atomic mass 15.9994. Naturally occurring oxygen consists of a mixture of three stable nuclides of relative masses 16 (99.759 atom percent), 17 (0.037 atom percent), and 18 (0.204 atom percent). The latter, commonly known as **heavy oxygen**, is useful as a tracer in studies of chemical and biochemical reaction mechanisms. The commonest valence is two. Oxygen is the most abundant element in the biosphere: in the atmosphere it occurs elementally in the form of molecules of the diatomic gas dioxygen, which comprises 20.95 by volume of dry air, and as traces of the gas **ozone** (i.e. trioxygen). The atmosphere also contains small amounts of the oxygen compounds carbon dioxide and water (vapour); almost half by weight of the surface of the Earth consists of oxygen in combined form, principally as water and silicates. **2** or **molecular oxygen** *symbol*: O₂; *the common name* for the gas correctly known as **dioxygen**.

oxygen-15 the radioactive nuclide of oxygen, ¹⁵O. It is prepared in a cyclotron by bombarding ¹⁴N with deuterons, the products being ¹⁵O and neutrons. It emits a positron, β^{+} (0.511 MeV), and has a half-life of 2 min; it is used in positron emission **tomography**.

oxygenase an enzyme that catalyses a reaction in which molecular oxygen is incorporated into an organic compound (the donor). Monoxygenases (EC class 1.13) act upon single donors, and dioxygenases (EC class 1.14) act upon paired donors.

oxygenate 1 to mix, supply, or treat with dioxygen; to saturate a fluid, especially blood, culture medium, etc., with dioxygen. **2** to cause the combination of an oxygen-carrying or oxygen-storing protein with dioxygen; to undergo such a reaction. —**oxygenation** *n*.

oxygenator an apparatus for oxygenation, especially of blood.

oxygen cycle the sum total of the processes via which atmospheric dioxygen is exchanged with the oxygen combined in organic compounds and carbon dioxide. Photosynthetic organisms, using solar energy, generate dioxygen from water and liberate it into the atmosphere, while heterotrophic cells take up atmospheric dioxygen to oxidize organic compounds and thereby provide energy. *Compare* **carbon cycle**.

oxygen debt the oxygen deficit that develops when a normally aerobic organism or tissue cannot increase its oxygen uptake sufficiently to match a temporarily increased energy requirement, as in muscular exercise. After the increased energy requirement ceases, this deficit has to be made good by a continuing increased rate of oxygen uptake until normal aerobic metabolism is restored.

oxygen demand *see* **biochemical oxygen demand**, **chemical oxygen demand**.

oxygen electrode a device for measuring dioxygen activity in a liquid or gas. It consists essentially of a silver-silver chloride anode in saturated potassium chloride solution and a platinum or gold cathode. When an electric potential is applied between these electrodes dioxygen is electrolytically reduced at the cathode, the current flowing being proportional to the dioxygen activity when the applied potential is 0.5–0.8 V. The electrodes are either directly exposed to the sample or, in the **Clark electrode**, separated from it by a thin dioxygen-permeable membrane in order to prevent deposition of interfering substances on the cathode.

oxygen-evolving complex *abbr.*: OEC; a protein-bound complex

of manganese and calcium in photosystem II that is responsible for splitting water to oxygen and reducing equivalents. *See* **photosystem**.

oxygen quotient (*sometimes*) the **metabolic quotient** with respect to dioxygen, *symbol*: Q_{O_2} .

oxygen toxicity toxicity resulting from excessive exposure to gaseous dioxygen. An atmosphere containing 100% oxygen is toxic to animals and cultured animal cells, bacteria, fungi, and plants. In humans, breathing 80–100% oxygen for 8 hours or more causes irritation of the respiratory passages, and after 24–48 hours it causes lung damage. In infants it causes bronchopulmonary dysplasia and retrolental fibroplasia (replacement of the retina by fibrous tissue). Hyperbaric oxygen is toxic to the central nervous system.

oxyhemoglobin *symbol*: HbO_2 ; the fully oxygenated form of **hemoglobin**. It is bright red in colour, and has a characteristic absorption spectrum.

oxyhydrogen reaction *an alternative name for* **knallgas reaction**.

oxymyoglobin *symbol*: MbO_2 ; the fully oxygenated form of **myoglobin**. It is bright red in colour, and has a characteristic absorption spectrum.

oxyntic acid-secreting; applied especially to the hydrochloric acid-secreting parietal cells of the gastric mucosa.

oxyntomodulin *an alternative name for* glucagon-37; *see* **enteroglucagon**.

oxyproline *an older name for* **hydroxyproline**. *Compare* **5-oxoproline**.

oxysome *an alternative name for* **elementary particle** (def. 2).

oxysterol receptor or **liver X receptor** (*abbr.*: LXR) either of two orphan receptors, LXR α and LXR β , whose endogenous ligands are oxysterols. Both occur in the enterohepatic system, with LXR α also present in adipose tissues and LXR β being more widely distributed. Both form obligate heterodimers with **retinoid X receptor** (which binds 9-*cis*-retinoic acid), and the dimer binds to specific hormone response elements on DNA.

oxytetracycline 5-hydroxytetracycline; an antibiotic that is similar in action to **tetracycline**. Proprietary names include Terramycin.

oxytocin or (*sometimes*) **ocytocin** *abbr.*: OXT; a heterodetic cyclic nonapeptide amide,

(Cys¹ and Cys⁶ form a disulfide bond). It is one of the two (or pos-

sibly more) hormones secreted by the neurohypophysis of the pituitary gland. It facilitates the ejection of milk by stimulating the myoepithelial cells in the mammary gland, and it may also aid parturition by stimulating contraction of the uterus. It is synthesized as a polypeptide precursor that is cleaved to oxytocin and neurophysin I (*see* **neurophysin**). Oxytocin was the first peptide hormone to be chemically synthesized. [*Note*: the spelling ocytocin is preferred on etymological grounds, the name being derived from the Greek *okytokos*, fast birth, rather than from the Greek *oxys*, acid, sharp; however, the spelling oxytocin is in wide use, esp. in the English language.] *See also* **vasopressin**.

oxytocin receptor any of a number of membrane proteins that bind oxytocin, and mediate its intracellular effects. Structurally, they are of the **7TM** type, characteristic of G protein-coupled receptors, and activate the **phosphatidylinositol cycle**.

+oyl *suffix (in chemical nomenclature)* denoting conversion (of a mono- or dicarboxylic acid) to the corresponding mono- or divalent acyl group by removal of hydroxyl from the carboxyl group; e.g. the univalent acyl group, hexanoyl, $\text{CH}_3\text{-(CH}_2\text{)}_4\text{-CO-}$, is derived from hexanoic acid, $\text{CH}_3\text{-(CH}_2\text{)}_4\text{-COOH}$. It is used also when the carbonyl oxygen atom of the acyl group has been replaced by =NH, =N-NH₂, =N-OH, or =S. *See also* **+yl**.

oz *symbol for* ounce.

ozone *symbol*: O₃; trioxygen; a colourless, highly reactive gas present in the stratosphere, where it is formed under the influence of short-wavelength ultraviolet radiation. It is also normally present in trace amounts in air, and is formed by the action of sunlight on hydrocarbons and nitrogen oxides – present in vehicle emissions. The latter process can lead to harmful accumulations of ozone at or near ground level. In contrast, stratospheric ozone protects the biosphere from highly damaging ultraviolet radiation, especially UV-C. Ozone is also produced by antigen-specific or monoclonal antibodies from excited dioxygen released by phagocytes or generated during inflammation. No enzyme is known that catabolizes ozone.

ozonolysis a method used for locating a double bond in an alkene. The alkene is treated with ozone, and the resulting ozonide is then cleaved to form two carbonyl compounds, one from each moiety of the parent compound.

Pp

p *symbol for* 1 pico+ (SI prefix denoting 10^{-12} times). **2** the negative logarithm to the base ten, as in pH, pK. **3** proton; it may be written as p^+ to indicate its charge. **4** a phosphoric residue (alternative to *P*). **5** the protein product of a gene; it is prefixed to the product's molecular mass to designate a particular entity, e.g. **p53**. **6** (*in atomic spectroscopy*) electron state $l = 1$.

p21 a protein (21 kDa) inhibitor of cyclin-dependent kinases of the G_1 phase of the cell-division cycle. It is induced by **p53** and is believed to contribute to cell-cycle arrest in the presence of damaged DNA, and to facilitate withdrawal from the cell cycle of cells undergoing terminal differentiation.

p53 a 53 kDa nuclear phosphoprotein originally discovered attached to large T-antigen in cells transformed with **simian virus 40**. It is a probable human cell cycle regulator and *trans*-activator (*see trans-acting*) that acts negatively to regulate cellular division by controlling a set of genes required for this process; one of the genes activated is an inhibitor of **cyclin-dependent protein kinases**. p53 acts as a tumour suppressor in some (not all) tissues; mutations in the p53 gene are the most common genetic alterations in human cancers. Wild-type p53 can suppress or inhibit the transformation of cells in culture either by viral or cellular oncogenes, and introduction of wild-type cDNA into a transformed cell in culture stops growth. Hence the p53 gene is classed as a **tumour-suppressor gene**. Three functional domains of p53 have been defined: an N-terminal transcriptional activation domain (residues 1–42), a central DNA-binding domain (residues 120–290), and a C-terminal regulatory domain (residues 311–393). The DNA-binding domain recognizes a Dna motif in genes that are activated by p53, and mutations in p53 that are associated with human cancers generally cluster in its DNA-binding domain.

p56 *see* Lck.

p *symbol for* 1 pressure (alternative to *P*). **2** partial pressure of a gas. The gas may be specified by a subscript or in parentheses; e.g. p_{O_2} or $p(O_2)$. **3** pyranose form (in monosaccharide symbolism); e.g. Glcp, glucopyranose; GalpA, galactopyranuronic acid. **4** pitch height (of a helix). **5** (bold italic) (electric) dipole moment (of a molecule), alternative to μ (bold italic). **6** (bold italic) momentum. **7** probability (alternative to *P*).

p- *prefix (in chemical nomenclature) denoting para-. Compare m-, o-*.

p50 *symbol for* the partial pressure of a gas at which a binding protein is 50% saturated with it.

p_{LR} *symbol for* the proportion of receptors or binding sites occupied by ligand L.

p_{LR}* *symbol for* the proportion of receptors in which ligand L occupies its binding site(s), and which are in an active state.

p_R *symbol for* the proportion of receptors or binding sites free of ligand.

P *symbol for* 1 peta+ (SI prefix denoting 10^{15} times). **2** poise. **3** phosphorus. **4** a residue of the α -amino (strictly, cyclic α -alkylamino) acid proline (alternative to Pro). *abbr. for* 5 phosphate or a phosphoric group, as in ATP. **6** (*in genetics*) parental generation. **7** a site near a peptidase cleavage site (*see* **peptidase P-site**).

P_i *symbol for* inorganic phosphate.

PO a myelin protein.

P1 a temperate bacteriophage whose natural hosts are *Shigella* spp. but which was used formerly for generalized transduction in *Escherichia coli* and is currently used as the basis for the **P1 cloning vector**, which can carry up to 100 kbp insert DNA. P1 prophage is a plasmid.

P2 a myelin protein.

P65 *see* synaptotagmin.

P81 *see* ezrin.

P450 or **P-450** any of a group of widely occurring heme-containing proteins that embraces various separately classified enzymes. They are named from the location of the Soret band (*see* **cytochrome absorption bands**) of the reduced CO complex at 450 nm. The group includes unspecific monooxygenase (EC 1.14.14.1), camphor 5-

monooxygenase (EC 1.14.15.1), alkane 1-monooxygenase (EC 1.14.15.3), steroid 11 β -monooxygenase (EC 1.14.15.4), **cholesterol monooxygenase (side-chain-cleaving)** (EC 1.14.15.6), prostacyclin synthase (EC 5.3.99.4), **thromboxane-A synthase** (EC 5.3.99.5), and probably chloride peroxidase (EC 1.11.1.10). This type of enzyme is also known as **cytochrome P450** (*see* this for more detail), and considered as a *b*-type **cytochrome**. The name heme-thiolate protein has been proposed on the grounds of a thiolate ligand at the heme being responsible for the group's unusual spectral and catalytic properties.

P680 or **pigment 680** a type of chlorophyll *a*, having an absorption maximum at 680 nm, that constitutes the reaction centre of **photosystem II** in most species. It has a redox potential of $>+0.81$ V; the oxidized form, P680⁺, is a powerful oxidant that can abstract electrons from water with the evolution of dioxygen. *See also* **chlorophyll**.

P700 or **pigment 700** a type of chlorophyll *a*, having an absorption maximum at 700 nm, that constitutes the reaction centre of **photosystem I**. It has a redox potential of approximately +0.5 V, its electron being used ultimately to reduce NADP via ferredoxin. *See also* **chlorophyll**.

P870 the special pair of bacteriochlorophyll *a* in the **photosynthetic reaction centre** of bacteria, so named because they have an absorption maximum of 870 nm.

P960 the special pair of bacteriochlorophyll *b* in the **photosynthetic reaction centre** of bacteria, so named because they have an absorption maximum of 960 nm.

P *symbol for* 1 pressure (alternative to *p*). **2** radiant power (alternative to Φ). **3** probability (alternative to *p*). **4** parity (of a wave function).

Pa *symbol for* pascal.

pA₂ the negative logarithm to the base 10 of the molar concentration of antagonist that makes it necessary to double the concentration of agonist needed to elicit the original submaximal response.

p[A]₅₀ the negative logarithm to the base 10 of the $[A]_{50}$ of an agonist. pEC₅₀ is the corresponding term for the EC₅₀ of an agonist (often used interchangeably with $[A]_{50}$).

PAB or **PABA** *abbr. for* para-aminobenzoate; para-aminobenzoic acid. *See* **p-aminobenzoic acid**.

PABA test an indirect test of pancreatic function in which the synthetic peptide *N*-benzoyl-L-tyrosyl-*p*-aminobenzoic acid (BT-PABA) is administered orally, usually with a small amount of [¹⁴C]-*p*-aminobenzoic acid (PABA). Normally the peptide is hydrolysed by chymotrypsin to PABA, which is absorbed and excreted in the urine, but in pancreatic insufficiency hydrolysis is much reduced.

PABP-2 *abbr. for* polyadenylation binding protein 2; a nuclear protein present in all tissues, but especially in skeletal muscle, that is needed for elongation of the poly(A) tail at the 3' untranslated region of eukaryotic mRNA. The human gene contains a (GCG) repeat for a polyalanine stretch at the N-terminus of the protein. The repeat number is increased in oculopharyngeal muscular dystrophy.

PACAP *abbr. for* pituitary adenylate cyclase-activating polypeptide; a preganglionic neuropeptide that stimulates expression of genes for chromogranins A and B (all of which have a cAMP response element in their promoter) in neuroendocrine cells. When released by melanopsin-containing retinal axons it transmits photic information.

pacemaker reaction any metabolic reaction whose rate depends on factors other than the amounts of enzyme or substrate. An enzyme catalysing such a reaction may be termed a **pacemaker enzyme**.

pachyman *see* callose.

pachytene the third phase of prophase I in meiosis.

package 1 (*in cell biology*) to surround (one or a number of macromolecules) with a membrane in the formation of a mature secretory granule. **2** (*in virology*) to enclose the nucleic-acid core of a virus particle with a protein shell (the capsid) to form a mature virion; to encapsidate.

packaging cell line any mammalian cell line modified for the production of recombinant retroviruses. They express essential viral genes that are lacking in the recombinant retroviral vector.

packaging extract a lysate of *E. coli* in which all but one of the capsid and tail proteins of bacteriophage lambda have been expressed. A mixture of two such lysates lacking different proteins is capable of packaging recombinant lambda genomes with high efficiency *in vitro*.

packing (*in chromatography*) the material (whether active solid, liquid held on solid support, or swollen gel) that is introduced into a column and that consists of or contains what is to become the stationary phase during a chromatographic separation.

packing density the ratio of the minimum (or actual) volume of an object, such as a molecule in a crystal or in solution, to the total volume it occupies. For a macromolecule or region of a macromolecule, it is the ratio of the volume enclosed by the van der Waals envelope of all atoms in the molecule or region to the total volume of the molecule or region. Theoretical values are 0.74 for close-packed spheres, 0.91 for infinite cylinders, and 1.0 for a continuous solid.

packing fraction the ratio of the relative atomic mass of a particular nuclide minus its nucleon number divided by its nucleon number. It is positive for the lightest and heaviest nuclides and negative for nuclides of intermediate mass.

Paclitaxel a proprietary name for taxol.

p21-activated protein kinase see **PAK**.

PAF *abbr.* for platelet-activating factor.

PAF-AH *abbr.* for platelet-activating factor acetylhydrolase. See **lipoprotein-associated phospholipase A2**.

PAGE *abbr.* for polyacrylamide gel electrophoresis.

PAGIF *abbr.* for polyacrylamide gel isoelectric focusing. See **polyacrylamide gel electrophoresis**.

PAH *abbr.* for *para*-aminohippurate; *para*-aminohippuric acid.

pair see **base pair**.

paired the gene for a sequence-specific DNA-binding homeobox segmentation protein in *Drosophila melanogaster*. It is one of a number of **pair-rule genes**, each of which specifies a simple alternation with a repeat distance of two segments. Their protein products are characterized by a paired-box DNA-binding domain of ≈128 amino acids, which consists of two subdomains each resembling a homeobox domain.

paired box see **paired**, **Pax genes**.

pair-rule gene any of the eight genes in *Drosophila* that regulate the segment polarity genes. Examples are *hairy*, *run1*, and *paired*.

pairwise alignment see **alignment**.

pairwise alignment algorithm see **alignment algorithm**.

PaJaMa experiment the nickname for a bacterial mating experiment carried out at l'Institut Pasteur, Paris, that showed that induction and repression of the enzyme β -galactosidase in *Escherichia coli* are regulated by two closely linked genes, one of which produces a cytoplasmic repressing substance that blocks the expression of the other. [From the names of the experimenters: Pardee, and French molecular biologists François Jacob (1920–) and Jacques Monod (1910–76).]

PAK *abbr.* for p21-activated protein kinase; any of a family of protein serine/threonine kinases activated by p21 and Cdc42/Rac (a Rho GTPase involved in regulation of the actin cytoskeleton), that are differentially expressed in mammalian cells. PAKs are upstream modulators of protein kinase cascades involved in regulation of apoptosis and in morphogenesis. They have an N-terminal p21-Cdc42/Rac-binding domain and a C-terminal catalytic domain. PAK1 localizes with actin filaments of the cytoskeleton. PAK2 is cleaved into its two domains by certain caspases. A mutation in PAK3 results in an X-chromosome-linked form of mental retardation.

palindrome 1 any linear arrangement of symbols, such as letters or digits, that has the same sequence from either end; e.g. noon, radar; 75311357; 'Madam, in Eden I'm Adam'. **2** (*in molecular biology*)

palindromic sequence a DNA sequence with a twofold rotational axis of symmetry (**dyad symmetry**). Confusingly the term is used in at least two senses: (1) to describe a region of local twofold rotational symmetry in duplex DNA, e.g.

and (2) to describe a sequence in a single polynucleotide strand that contains an inverted repeat, e.g. 5'-TGA-AGT-3'. It is also applied to a region of a single- or a double-stranded polynucleotide that is capable of forming one or more **hairpins** containing palindromes of the first type; an example is shown at **cruciform**. Examples of palindromes are **operators** and **restriction sites** but, in general, any stem-loop in RNA must have a corresponding palindrome in the DNA from which the RNA was transcribed. —**palindromic adj.**

pallidin any of a group of endogenous carbohydrate-binding proteins (**lectins**) produced by cells of the slime mould *Polysphondylium pallidum* during differentiation. Similar to **discoidin**, they may be involved in cell adhesion.

palmitate 1 *numerical symbol:* 16:0; *the trivial name for* hexadecanoate, $\text{CH}_3-[\text{CH}_2]_{14}-\text{COO}^-$, the anion derived from palmitic acid (i.e. hexadecanoic acid), a saturated straight-chain higher fatty acid. **2** any mixture of free palmitic acid and its anion. **3** any salt or ester of hexadecanoic acid. See also **palmitoyl**.

palmitate synthase see **fatty-acid synthase complex**.

palmitic acid hexadecanoic acid; a saturated straight-chain fatty acid having sixteen carbon atoms per molecule, and a major component of plant and animal fats. See **palmitate**.

palmitoleate 1 *numerical symbol:* 16:1(9); *the trivial name for* (Z)-hexadec-9-enoate, $\text{CH}_3-[\text{CH}_2]_5-\text{CH}=\text{CH}-[\text{CH}_2]_7-\text{COO}^-$, the anion derived from palmitoleic acid, (Z)-hexadec-9-enoic acid, a mono-unsaturated straight-chain higher fatty acid. **2** any mixture of free palmitoleic acid and its anion. **3** any salt or ester of 9-hexadecenoic acid. See also **palmitoleoyl**.

palmitoleic family (of polyunsaturated fatty acids) a series of polyenoic acids in which the hydrocarbon chain terminates with the alkenyl grouping $\text{CH}_3-[\text{CH}_2]_5-\text{CH}=\text{CH}-$ (as in palmitoleic acid (see **palmitoleate**)); there are three other series of such acids, i.e. the **linoleic family**, **linolenic family**, and **oleic family**. Members of the palmitoleic family can be synthesized from palmitic acid via palmitoleic acid by chain elongation and/or desaturation, but in mammals not from linoleic, (9,12,15)-linolenic, or oleic acids; the series includes *cis*-vaccenic acid.

palmitoleoyl *symbol:* ΔPam ; *the trivial name for* (Z)-hexadec-9-enoyl, $\text{CH}_3-[\text{CH}_2]_5-\text{CH}=\text{CH}-[\text{CH}_2]_7-\text{CO}-$ (*cis* isomer), the acyl group derived from palmitoleic acid (i.e. (Z)-hexadec-9-enoic acid). It is a relatively minor component of plant and animal lipids. The chain is synthesized metabolically by the action of a Δ^9 -desaturase on palmitoyl-CoA.

palmitoyl *symbol:* Pam; *the trivial name for* hexadecanoyl, $\text{CH}_3-[\text{CH}_2]_{14}-\text{CO}-$, the acyl group derived from palmitic acid (i.e. hexadecanoic acid). This is one of the major fatty-acid components of plant and animal lipids; together with stearic acid it represents a high proportion (often around 30%) of the fatty-acid content of dietary and other lipids. It acts as a precursor in mammals for a family of unsaturated fatty acids in which all double bonds are nine or more carbons from the methyl terminus. The chain is synthesized metabolically from acetyl-CoA as palmitate (in mammals) or palmitoyl-CoA (in yeast), the product of fatty-acid synthase. See **fatty-acid synthase complex**.

palmitoyl-protein thioesterase EC 3.1.2.22. a lysosomal enzyme that cleaves the thioester linkage formed by a palmitoyl moiety with a cysteine side chain near a transmembrane segment of an integral membrane protein. Mutations in this gene on 1p32 cause infantile neuronal lipofuscinosis and progressive myoclonic epilepsy.

palmityl 1 or **cetyl** a common name for hexadecyl, $\text{CH}_3-[\text{CH}_2]_{14}-\text{CH}_2-$, the alkyl group derived from hexadecane. **2** a former name (now incorrect) for **palmitoyl**.

palytoxin any of a group of structurally very similar potent neurotoxins isolated from the marine zoanthid *Palythoa toxica* or other *Palythoa* spp. Each consists of a single carbon chain of 115 carbon atoms containing 64 chiral centres and seven double bonds, and terminating in nitrogen-containing groups; there are 128 carbons in all and a further double bond in a methylene group. The chain bears numerous hydroxyl groups and a number of methyl groups, and in several places it is folded and formed into pyran rings. Palytoxin is the most deadly nonproteinaceous material isolated, having 50

times the toxicity of **tetrodotoxin** in mice. The number of stereoisomers is $2^{64} = 18446744073709551620$ (not including possible *E/Z* variations at the double bonds!).

Pam symbol for **palmitoyl** (i.e. hexadecanoyl).

PAM abbr. for **1** point accepted mutation. See **PAM matrix**. **2** peptidylglycine α -amidating monooxygenase. See **peptide amidation**.

PAM matrix abbr. for point accepted mutation matrix; see **point accepted mutation, substitution matrix**.

pancreas a compound gland, occurring in the abdominal cavity of most vertebrates, that has both exocrine and endocrine functions. The major (exocrine) part consists of acinar tissue, which secretes **pancreatic juice** into the upper part of the gut (duodenum in mammals). Within this acinar tissue are scattered numerous (endocrine) **islets of Langerhans**, containing notably A cells, secreting **glucagon**, B cells, secreting **insulin**, and D cells, secreting **somatostatin**. —**pancreatic adj.**

pancreastatin a 49-residue peptide hormone that inhibits glucose-induced insulin release and exocrine pancreatic secretion. It was originally isolated from porcine pancreas, where it is colocalized with insulin, glucagon and somatostatin, but it is part of the sequence of **chromogranin A** and is thus found in tissues where the chromogranin gene is expressed, including most endocrine cells.

pancreatic cholera an alternative name for **Verner–Morrison syndrome**.

pancreatic diabetes an older term for insulin-dependent diabetes mellitus.

pancreatic DNase I an alternative name for **deoxyribonuclease I**.

pancreatic hormone or **pancreatic polypeptide** abbr.: PP; a polypeptide present in the **PP cells** of the pancreas. Avian pancreatic polypeptide, known as aPP (from chicken and turkey pancreas), and bovine, human, ovine, and porcine homologues, known as bPP, hPP, oPP, and pPP, respectively, have been identified. All contain 36 amino-acid residues with C-terminal tyrosinamide and show considerable sequence homology. The plasma PP level rises rapidly after feeding, especially with protein foods, and with fasting, exercise, and hypoglycemia. The hormone decreases food absorption and pancreatic exocrine secretion. The sequence of human PP is: APLEPVYPGDNATPEQMAQYAADLRRYINMLTR-PRY(NH₂).

pancreatic islet an alternative name for **islet of Langerhans**.

pancreatic juice a slightly alkaline digestive juice secreted by the exocrine pancreas into the upper part of the small intestine. It contains numerous enzymes and inactive enzyme precursors including α -**amylase**, chymotrypsinogen, **lipase**, procarboxypeptidase, proelastase, phospholipase A₂, ribonuclease, and trypsinogen. Its high concentration of hydrogencarbonate ions helps to neutralize the acid digesta from the stomach.

pancreatic lipase a Ca²⁺-requiring triacylglycerol lipase (EC 3.1.1.3) that is secreted into the intestine by the exocrine pancreas when this is stimulated by cholecystokinin in response to ingestion of food. It degrades triacylglycerols, partially or completely, to fatty acids and glycerol in the intestine; it acts at an ester–water interface. It is a glycoprotein with sequence similarity with other lipases.

pancreatic polypeptide abbr.: PP; another name for **pancreatic hormone**.

pancreatic ribonuclease see **ribonuclease**.

pancreatic thread protein or **pancreatic stone protein** (abbr.: PSP); a C-type lectin that may inhibit spontaneous calcium carbonate precipitation, and one of the major secretory proteins of the human exocrine pancreas. It is found in acinar cells of pancreas and (in smaller amounts) in the brain. It is a major soluble protein of human pancreatic calculi, and a Ca²⁺-binding phosphoprotein present in zymogen granules of pancreatic acinar cells, and secreted in pancreatic juice of normal subjects and calculus formers. It inhibits calcium carbonate precipitation from the juice. The protein is rich in aromatic amino acids. Between pH 5.4 and 9.2, it undergoes reversible fibril formation. It is also typically characteristic of infant brains. There is increased expression of PSP-like proteins in Down's syndrome and Alzheimer's disease.

pancreatic trypsin inhibitor abbr.: PTI; a serine proteinase inhibitor, correctly known as **pancreatic secretory trypsin inhibitor**. A

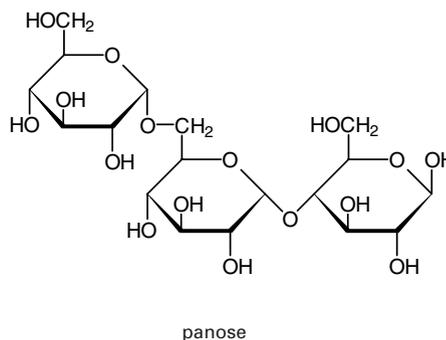

protein isolated from bovine pancreas, it forms a crystalline complex with trypsin and is relatively heat-stable in trichloroacetic acid solution. It controls trypsin activation of zymogens. The bovine protein has the sequence: NILGREAKCTNEVNGCPRIYN-PVCGTDGVTYSNECLLCMENKERQTPVLIQKSGPC. The 3-D structure is also known, and it is a favoured model for testing protein-folding algorithms. It was also formerly known as **Kunitz and Northrop inhibitor**.

pancreozymin abbr.: PZ; a hormone having secretagogic activity on the exocrine pancreas and extractable from duodenal mucosa. It is identical with **cholecystokinin**.

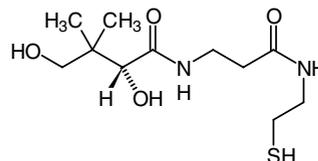

PANK abbr. for pantothenate kinase.

panning (in cell biology) a method for enriching a population of cells, or phages, displaying peptides or fragments of antibodies by allowing them to bind to ligands immobilized on a solid surface such as that of a **microtitre plate**. Washing the wells of the plate removes nonadherent or weakly adherent cells or phages, leaving those adhering as a result of stronger interactions, to be collected for further study. Several cycles of enrichment are used.

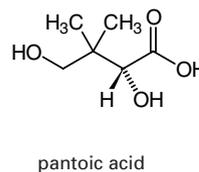

panose an oligosaccharide, Glc(α 1-6)Glc(α 1-4)Glc; it is found in the fungus *Aspergillus niger*.

pantetheine *N*-pantothencysteamine; the *D*-enantiomer is a growth factor for *Lactobacillus bulgaricus*, and is an intermediate in the pathway for the biosynthesis of coenzyme A in mammalian liver and some microorganisms.

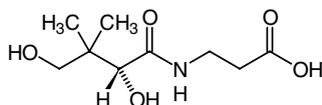

pantoate 1 the anion, HO–CH₂–C(CH₃)₂–CH(OH)–COO[–], derived from pantoic acid (i.e. (*R*)-2,4-dihydroxy-3,3-dimethylbutyric acid). **2** any salt or ester of pantoic acid.

pantophysin a member of the **physin** family of proteins. It is ubiqui-

tously expressed, is homologous with synaptophysin, and is present in constitutive transport vehicles.

pantothenate 1 the anion, $\text{HO-CH}_2\text{-C(CH}_3)_2\text{-CH(OH)-CO-NH-CH}_2\text{-CH}_2\text{-COO}^-$ (i.e. *N*-pantoyl- β -alanine anion), derived from pantothenic acid, a B vitamin complex; only the *D*-(*R*)-enantiomer is biologically active. **2** any salt of pantothenic acid.

pantothenic acid

pantothenate kinase *abbr.*: PANK. EC 2.7.1.33; a kinase enzyme that is specific for phosphorylation of pantothenate to 4'-phosphopantothenate, being the first reaction in the biosynthesis of coenzyme A. Many mutations in the gene for PANK2 (locus at 20p13) produce enzyme deficiency and Hallervorden-Spatz syndrome, a neurodegenerative disease involving accumulation of iron in the brain.

pantothenyl the acyl group, $\text{HO-CH}_2\text{-C(CH}_3)_2\text{-CH(OH)-CO-NH-CH}_2\text{-CH}_2\text{-CO-}$, derived from pantothenic acid; coenzyme A is a *D*-(*R*)-pantothenyl derivative.

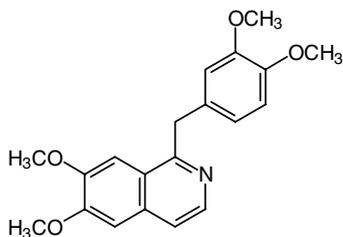

pantoyl 1 the acyl group, $\text{HO-CH}_2\text{-C(CH}_3)_2\text{-CH(OH)-CO-}$, derived from pantoic acid, 2,4-dihydroxy-3,3-dimethylbutyric acid.

PaO *abbr.* for pheophorbide a oxygenase.

PAP *abbr.* for peroxidase-antiperoxidase.

papain or **papaya peptidase I** EC 3.4.22.2; a cysteine endopeptidase obtained from the latex, leaves, and unripe fruit of the papaya (or pawpaw) tree, *Carica papaya*. It will preferentially hydrolyse peptide bonds at the carbonyl end of Arg, Lys, and Phe residues (but never Val), with preference for large hydrophobic residues at the P2 position. It also has esterase, thiolesterase, transamidase, and transesterase activity. Papain is unusually stable to elevated temperatures and to denaturing agents, and consists of a single polypeptide chain of 212 amino-acid residues.

papaverine 1-[(3,4-dimethoxyphenyl)methyl]-6,7-dimethoxyisoquinoline; a constituent of **opium** that acts as a smooth muscle relaxant; this action is thought to be due to phosphodiesterase inhibitory activity and blockade of membrane calcium channels. Like codeine and morphine it is a metabolic derivative of (*S*)-reticuline.

paper chromatogram the visible result of a chromatographic separation effected on paper.

paper chromatography *abbr.*: PC; a technique of **chromatography**, applicable to microgram quantities of soluble substances, in which specially prepared filter paper, **chromatography paper**, forms the support for the stationary phase. The latter is commonly a film of water held by adsorption on the cellulose fibres of the paper and in equilibrium with a water-immiscible liquid or liquid mixture, which forms the mobile phase. A solution of a sample is applied near one end of a strip of paper, allowed to dry, and the mobile phase allowed to flow over the strip from that end. If the sample consists of

only one component, development using an appropriate method of detection will reveal a single spot at a characteristic distance from the origin relative to that travelled by the mobile phase; in general, a mixture will give rise to a number of spots each occupying a different and characteristic position. Separations occur essentially by partition between the mobile and stationary phases, with some contribution, under certain conditions, attributable to adsorption or ion-exchange onto the paper support. An elaboration of the technique uses a square of paper on which two successive separations are effected at right-angles using mobile phases of differing separatory powers to produce a two-dimensional pattern of spots on the paper. With suitable treatment of the paper and an appropriate choice of the composition of the two phases, reversed-phase partition chromatography on paper may be effected. Since cellulose is chiral, some enantiomer separations are possible.

paper electrophoresis a type of **zone electrophoresis** on (filter) paper.

Papovaviridae a family of DNA viruses, most or all of which are, under suitable conditions, oncogenic in vertebrate hosts. The virion, 45–55 nm in diameter, consists of a nonenveloped icosahedral capsid with 72 capsomeres, and contains a circular DNA genome.

papovavirus any virus belonging to the family **Papovaviridae**. The name derives from papilloma, polyoma, and vacuolating agent, an early name for **simian virus 40**.

PAPP-A *abbr.* for pregnancy-associated plasma protein A; a plasma protein first found in the serum of pregnant women but also present in men. It is a zinc metalloprotease secreted by fibroblasts and cleaves **insulin-like growth factor binding protein (IGFBP)-4** to release insulin-like growth factor (IGF).

PAPS *abbr.* for 3'-phosphoadenosine-5'-phosphosulfate; i.e. adenosine 3'-phosphate 5'-phosphosulfate.

par+ a variant form of **para+** (before a vowel).

PAR *abbr.* for protease-activated G-protein-coupled receptor; any G-protein-coupled membrane receptor of platelets and endothelial cells that becomes activated on binding thrombin and cleavage of the extracellular segment of the receptor. Most mouse embryos that lack PAR1 die in mid-gestation.

para 1 characterized by or relating to (substitution at) two ring-carbon atoms separated by two others in a monocyclic aromatic compound. **2** (followed by to) at a position in a benzene ring next but two to a particular (specified) substituent. *See also para-*.

para+ or (before a vowel) **par+** prefix indicating beside or near; beyond; resembling; defective or abnormal.

para- *abbr.*: *p-*; prefix (in chemical nomenclature) denoting an isomer of a disubstituted monocyclic aromatic compound in which the substituents are attached at positions 1 and 4 of the ring. *Compare meta-, ortho-*.

parabiont either individual of a pair united in **parabiosis**.

parabiosis the state or condition of two individual animals being functionally united, either naturally, as in Siamese twins, or as a result of an experimental procedure. —**parabiotic** *adj.*

paracasein an alternative name (*esp. US*) for **casein** (def. 2).

paracentric (in cytogenetics) describing an inversion of part of a chromosome that does not span the centromere, and is thus confined to one arm of the chromosome. *Compare pericentric*.

paracetamol *see acetaminophen*.

paracrine 1 describing or relating to a regulatory cell that secretes an agonist into intercellular spaces in which it diffuses to a target cell other than that which produces it; describing or relating to such an agonist. **2** such an agonist; a **paramone**. *Compare endocrine, neurocrine, neuroendocrine*.

paracrystal any assemblage of molecules or particles having a certain degree of order but one that is insufficient for it to be considered a true crystal. —**paracrystalline** *adj.*; **paracrystallinity** *n*.

paradoxin or **pardaxin** any of several ichthyotoxic, neurotoxic peptides, isolated from the defence secretion of the Red Sea Moses sole fish, *Paradachirus marmoratus*, or the Pacific sole, *Paradachirus pavoninus*, that act as a shark repellent. Each consists of 33 amino acids, with hydrophilic C-terminal and hydrophobic N-terminal re-

gions, and with physical and pharmacological similarities to **melittin**, but no sequence similarity.

paraffin 1 an obsolete term for **alkane**. **2** or **paraffin oil** or **kerosene** or **kerosine** any liquid mixture, consisting mainly of alkanes, with a boiling point range of 150–300 °C and relative density range of 0.78–0.82. **3** an alternative name for **paraffin wax**. Compare **liquid paraffin**.

paraffin wax any waxy mixture of higher alkanes, obtained as a residue from the distillation of petroleum, with a relative density of ≈0.9 and a melting point range of 45–65 °C.

Parafilm the proprietary name for a flexible, moisture-proof, thermoplastic tissue useful for temporarily sealing small containers.

parafollicular cell an alternative name for **C cell** (when found in the thyroid gland).

parafusin an evolutionarily conserved phosphoglycoprotein involved in exocytosis. It is rapidly dephosphorylated via a Ca²⁺-dependent process when secretagogues induce exocytosis in competent cells.

parahematin or (*esp. Brit.*) **parahaematin** a former name for **ferrihemochrome**.

parahemophilia a bleeding disorder due to deficiency of factor V. See **blood coagulation**.

parallel 1 (*in biochemistry*) describing a pair of linear structures, such as two polynucleotide or polypeptide chains, that are polarized or asymmetric in the same direction. **2** (*in physical chemistry*) denoting the spins of a pair of electrons, occupying the same atomic or molecular orbital, that are described by the same spin quantum number. Compare **antiparallel**. **3** (*in electricity*) describing an electrical component that is connected to the same two points in a circuit as another component; describing two or more components that are so connected.

parallel dichroism see **dichroic ratio**.

parallelism the quality or state of being parallel; similarity in corresponding details or in evolutionary pattern.

paralogue or (*esp. US*) **paralog** a gene, protein, or biopolymeric sequence that is evolutionarily related to another by descent from a common ancestor, having diverged as a result of a gene duplication event within an organism. Paralogues usually perform different but related functions within that organism as, for instance, human red and green opsins. —**paralogous** *adj.*

paramagnetism the property displayed by substances that have a positive but small magnetic susceptibility, due to the presence in them of atoms with permanent magnetic dipoles caused by unpaired electron spins (with a contribution from the orbital motion of the electrons). These dipoles tend to align themselves in the direction of an applied magnetic field but no permanent magnetism is conferred on such substances. Compare **diamagnetism**, **ferromagnetism**. —**paramagnetic** *adj.*

paramecium (*pl. paramecia*) any freshwater protozoan belonging to the genus *Paramecium*. Typically 50–300 μm in length, they are ovoid and uniformly ciliated. See also **kappa particle**.

parameter 1 (*in mathematics*) an unknown quantity that is a constant in a particular context but that may have different values in other (similar) contexts; e.g. the coefficient *b* in the general equation, $y = bx + c$, representing a family of straight lines. **2** (*in statistics*) a numerical characteristic of a population (as opposed to that of a sample of such a population). **3** any distinguishing characteristic of something, especially one to which a measured value is or can be ascribed. —**parametric** *adj.*

paramomycin an aminoglycoside antibiotic produced by *Streptomyces paramomycinus*. Its actions are similar to those of **neomycin**.

paramone a proposed name for **paracrine** agonist, derived as a contraction of 'paracrine hormone'.

paramylon a storage polysaccharide occurring in *Euglena gracilis*. It comprises a backbone of β1→3-glucopyranose units with side chains joined by α1→6 linkages.

paramyosin a two-chain, coiled-coil, α-helical ~200 kDa protein that forms the core protein of the thick filaments of a number of invertebrate muscles.

paramyxovirus any RNA animal virus of the family Paramyxoviridae (distinguish from the genus Paramyxovirus), in class V of the Baltimore classification. **Paramyxoviruses** consist of enveloped, pleo-

morphic particles ≈150 nm in diameter with helical nucleocapsids, 1000 nm long and 18 nm in diameter. They contain single-stranded RNA (minus strand) of 7 MDa plus virion polymerase. The group includes viruses causing mumps, measles, Newcastle disease of chickens, and distemper of dogs, and the morbilliviruses, pneumoviruses, and parainfluenza viruses.

paranemic describing the nature of the coiling of a double-stranded helix in which the two strands are not intertwined, i.e. they may be separated without uncoiling. Compare **plectonemic**.

paraoxonase arylalkylphosphatase, EC 3.1.8.1; an enzyme that hydrolyses organophosphates. The name derives from its ability to hydrolyse paraoxon, diethyl-p-nitrophenyl phosphate, a cholinesterase inhibitor that is used as a pesticide. The enzyme has anti-oxidant properties and its physiological substrates are probably the products of lipid peroxidation.

parapepsin I an alternative name for **pepsin B**.

parapepsin II an alternative name for porcine **gastricsin** (i.e. pepsin C).

paraplegin a mitochondrial **AAA protease** (88 kDa) that is highly homologous with yeast metalloproteases and has proteolytic and chaperone functions at the inner mitochondrial membrane. It is encoded on nuclear DNA. Mutated paraplegin results in hereditary spastic paraplegia and respiratory chain defects.

paraprotein name originally given to any plasma protein that gave an abnormal band on electrophoresis, derived from **para** + protein. Usually, such a protein is a monoclonal immunoglobulin derived from neoplastic plasma cells, and present at abnormally high concentration in the blood plasma. Such proteins are seen as a discrete band in the gamma-globulin region, but they may appear elsewhere if the paraprotein is IgA or IgM. Examples are proteins characteristic of a **myeloma**, e.g. **Bence-Jones protein**, amyloid proteins, **Waldenström's macroglobulinemia**, or cryoglobulins. Some paraproteins are not abnormal, e.g. the immunoglobulin that arises as a result of a severe bacterial infection.

paraproteinemia or (*esp. Brit.*) **paraproteinaemia** the presence in blood plasma of **paraprotein**.

Paraquat methyl viologen; 1,1'-dimethyl-4,4'-bipyridinium dichloride; a nonselective herbicide whose action requires direct contact with the plant. It is highly toxic to humans and other animals if ingested in undiluted form.

parasite any organism that spends all or part of its life cycle in (**endoparasite**) or on (**ectoparasite**) another living organism of a different species (its **host**), from which it obtains nourishment and/or protection, and to which it is usually detrimental. Compare **symbiont**.

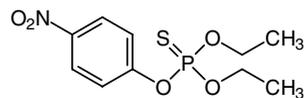

parastatin a 73-amino-acid peptide hormone, *M_r* 11000, that inhibits **parathyrin** secretion. Porcine parastatin has the amino-acid sequence:

LSFRAPAYGFRGPGQLRRGWPRSSREDSVEAGLPLQVRXYLEEKKEEEGSANRPEDQELSLSAIEAELEK.

Activity resides in a 19-amino-acid N-terminal fragment; that from rat has the sequence: LSFRRARYGFRDPPGQLRR. It is synthesized as part of the sequence of **chromogranin A**.

paratartaric acid an old name for racemic DL-tartaric acid. The resolution of this acid into the D- and L-enantiomers by Pasteur was a landmark experiment in stereochemistry. See **tartaric acid**.

parathion O,O-diethyl O-p-nitrophenyl phosphorothioate; a compound that acts as an inhibitor of cholinesterase through covalent bonding to the esteratic site of the enzyme. It is used as a chemical warfare agent and insecticide.

Parathormone a proprietary name for **parathyrin**.

parathyrin or **parathyroid hormone** (*abbr.:* PTH); a 9.5 kDa polypeptide hormone of 83 amino-acid residues (bovine). It is derived from a 12.5 kDa precursor. Parathyrin acts in con-

junction with **calcitonin** and other hormones to control calcium and phosphate metabolism; it elevates the blood calcium level by dissolving the salts in bone and preventing their renal excretion. Its effects are mediated by a G-protein-associated membrane receptor. Several mutations in the receptor cause a rare form of short-limbed dwarfism (or metaphyseal chondrodysplasia). Mutations that lead to absence or dysfunction of the G_{Sa} subunit cause pseudohypoparathyroidism type 1a, in which there is also resistance to a wide variety of other hormones whose effects are mediated by this subunit. *Proprietary name:* Parathormone.

parathyroid 1 situated near the thyroid gland. **2** of, pertaining to, or produced by the parathyroid gland. **3** the parathyroid gland.

parathyroid gland an endocrine gland of higher vertebrates; there are typically two pairs, located near or within the thyroid. They develop from the gill pouches, and secrete **parathyrin**.

parathyroid hormone *abbr.:* PTH; *an alternative name for parathyrin.*

parathyroid hormone-related protein *abbr.:* PHRP; a protein (141 amino acids) that is homologous in the N-terminal region with parathyroid hormone, has effects similar to this, and binds the same receptor. It is present in breast and milk, kidney, brain, and other tissues, especially during intrauterine life, and seems to function largely in paracrine fashion. It is secreted by many tumours and is the major cause of malignancy-associated hypercalcemia. It may be a polyhormone because residues 1–36 are parathyroid hormone-like, residues 38–94 effect calcium transport in the placenta and bicarbonate transport in the kidney, and residues 107–139 constitute **osteostatin**. Homozygous gene knockout in mice is often lethal during embryogenesis or produces abnormalities throughout the skeleton.

paratope the part of an antibody, formed by the hypervariable loops of the **variable regions**, that binds to an **epitope**.

paratose 3,6-dideoxy-D-glucose; 3,6-dideoxy-D-ribo-hexose; a monosaccharide that occurs in type A O-antigen chains of the lipopolysaccharide on the outer membrane of certain species of *Salmonella*.

Parazoa a subkingdom of multicellular invertebrate animals comprising the sponges (phylum Porifera).

parenchyma 1 (*in botany*) in higher plants, any soft tissue consisting of thin-walled, relatively undifferentiated living cells. **2** (*in zoology*) the tissue constituting the essential or specialized part of an organ, as distinct from supportive tissue, blood vessels, etc. —*parenchymal adj.:* **parenchymatous adj.**

parenchymal liver cell *see* **hepatocyte**.

parent 1 any organism that has given rise to another such organism, whether sexually or asexually. **2** a precursor of some derived entity; applied, e.g., to a cell, a virus, a chromosome or molecule of DNA, or a radionuclide. **3 parent compound** (*in chemical nomenclature*) the member of a group of related compounds that has the simplest chemical structure and that forms the basis for naming the others. —*parental adj.*

parental imprinting *see* **imprinting**.

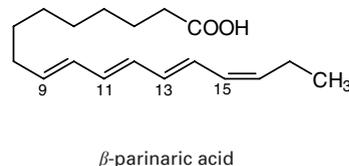

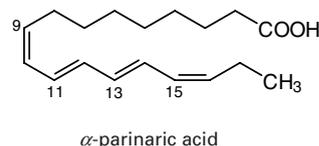

parenteral 1 located or occurring outside the intestine. **2** any route other than via the gastrointestinal tract, especially by injection. —*parenterally adv.*

PARG *abbr. for* poly(ADP-ribose) glycohydrolase.

parietal 1 of, pertaining to, or forming part of the wall of a body cavity or similar structure; e.g. the hydrochloric-acid-secreting **parietal cells** of the gastric mucosa, also known as oxyntic cells. **2** of or relating to the parietal bones of the skull.

parietal layer *see* **serous membrane**.

parinaric acid any octadeca-9,11,13,15-tetraenoic acid; two isomers are found in *Parinarium laurinum*, namely the (9Z,11E,13E,15Z)-isomer (α - or *cis*-parinaric acid) and the (9E,11E,13E,15Z)-isomer (β - or *trans*-parinaric acid). Both are useful as probes in membrane studies, *trans*-parinaric acid especially, as it partitions preferentially into the less fluid regions of membrane lipids with increased quantum yield. They inhibit neutrophil elastase.

parkin a **ubiquitin-protein ligase** whose substrate is a glycosylated form of α -synuclein (α -Sp22). The substrate accumulates in parkin-deficient brain. The parkin gene at 6q25.2-q27 encodes a protein (465 residues) whose N-terminal 76 residues are homologous with ubiquitin and whose C-terminal region contains two **RING fingers**. Mutations in the gene are associated with an autosomal recessive form of **Parkinson's disease**.

Parkinson's disease or **parkinsonism** a progressive disorder of the central nervous system characterized by tremor and impaired muscular coordination, thought to be due to defective dopaminergic transmission in some parts of the brain. There is a loss of dopaminergic neurons connecting the substantia nigra with the striatum, resulting in loss of dopaminergic inhibition in the striatum, with resulting cholinergic hyperactivity. Therapy is aimed at replacement of dopamine, achieved by administration of L-dopa, which is converted to dopamine within the brain (dopamine itself does not cross the blood-brain barrier). *See also* **MPTP**. [After James Parkinson (1755–1824), British palaeontologist and surgeon, who first described the disease in 1817.]

Park nucleotide UDP-N-acetylmuramyl pentapeptide; an intermediate in the biosynthesis of peptidoglycan in the cell walls of most bacteria. [After James Theodore Park (1922–).]

P450 arom *an alternative name for* **aromatase**.

paromomycin an antibiotic that, like streptomycin, increases the error rate of translation by binding to the 30S ribosomal subunit of prokaryotes and distorting their A site.

parotid gland either of a pair of **salivary glands** situated near each ear in mammals. The duct runs forwards and empties into the oral cavity.

paroxysmal nocturnal hemoglobinuria an acquired hemolytic anemia in which a clone of erythrocytes, derived from a hemopoietic stem cell that has acquired a somatic mutation, undergoes complement-mediated chronic intravascular hemolysis with consequent hemoglobinuria. It arises following any of numerous mutations in the gene at Xp22.1 for the enzyme that attaches the glucosamine moiety to phosphatidylinositol in the production of GPI-anchored proteins. This causes a lack on erythrocytes of CD55 and CD59, which normally protect the erythrocytes against the action of complement. Deficiency of CD55 alone is a rare cause of the disorder.

PARP *abbr. for* 1 procyclin. **2** proline/arginine-rich protein.

PARP-1 *abbr. for* poly(ADP-ribose) polymerase 1; in mammals, a highly conserved protein (113 kDa) that is strongly activated by DNA strand breaks, and participates in modulating DNA base excision repair, apoptosis, and necrosis. It includes a DNA-binding domain with 23 zinc finger motifs, and a poly(ADP-ribose) polymerase catalytic domain. Mouse gene knockouts for this protein are remarkably resistant to myocardial infarction, stroke, shock, diabetes mellitus, and neurodegeneration. *See also* **PARP-2**.

PARP-2 *abbr. for* poly(ADP-ribose) polymerase 2; in mammals, a 62 kDa protein that catalyses poly(ADP-ribose) formation, being activated by DNA strand breaks. Its activity supplements that of **PARP-1** in mouse gene knockouts for this protein.

parse to analyse amino acid sequences or nucleotide base sequences during the construction of multiple sequence alignments when determining homology.

parsimony 1 (*in computing*) an algorithm used for determining sequence relationships in macromolecules. **2** (*in genetics*) the construction of evolutionary trees from protein and nucleic-acid sequences. It maximizes the genetic likeness associated with common ancestry, whilst minimizing the incidence of convergent mutation, and provides a way to find the best genealogical hypothesis from sequence data.

parthenocarp the formation of fruit without the setting of seeds. It occurs naturally, but can be induced by spraying flowers with gibberellic acid (*see gibberellin*) to produce crops of seedless fruit.

parthenogenesis the development of a new individual from an unfertilized female gamete. —**parthenogenetic** *adj.*; **parthenogenetically** *adv.*

partial agonist an agonist that is unable to evoke the maximal response of a biological system, even at a concentrations sufficient to saturate the specific receptors.

partial derivative (*in mathematics*) the derivative of an expression containing two or more independent variables that is obtained by differentiating the expression with respect to only one of them, the remaining variable or variables being considered constant.

partial hydrolysate any mixture of monomers and oligomers resulting from a limited degree of chemical hydrolysis of a biopolymer or from its exposure to a specific hydrolytic enzyme.

partial inhibition a type of nonlinear enzyme inhibition in which saturation of the enzyme with inhibitor does not decrease the rate of the enzyme-catalysed reaction to zero.

partial inverse agonist an **inverse agonist** that evokes a submaximal response in a biological system, even at a concentration sufficient to saturate the specific receptors. At high concentrations it will diminish the actions of a full inverse agonist. *Compare antagonist, partial agonist.*

partially overlapping code *see overlapping code.*

partially overlapping gene *see overlapping gene.*

partial molar quantity a function of any particular extensive property (e.g. enthalpy, entropy, Gibbs energy, heat capacity, internal energy, volume) of a specified component of a single-phase multicomponent system that describes how that property varies, at constant pressure and temperature, with variation of the concentration of the component when the change in the property is expressed per mole of the component. Partial molar Gibbs energy is more usually known as **chemical potential**. *Compare partial specific quantity.*

partial pressure *symbol:* p_B or $p(B)$ (for a gas B); the pressure exerted by one particular gas in a mixture of nonreacting gases. It is defined as the pressure the gas would exert if it alone were present and occupied the whole volume of the mixture at the same temperature, and is equal to the product of the amount-of-substance fraction of the gaseous component in question and the total pressure of the gaseous system. *Compare tension. See also p_{50} .*

partial pressures, law of *see Dalton's law of partial pressures.*

partial specific quantity a function of any particular extensive property (e.g. enthalpy, entropy, Gibbs energy, heat capacity, internal energy, volume) of a specified component of a single-phase multicomponent system that describes how that property varies, at constant pressure and temperature, with variation of the concentration of the component when the change in the property is expressed per unit mass of the component. *Compare partial molar quantity.*

partial specific volume (of a solute) *symbol:* v_B ; an instance of a **partial specific quantity**, defined as the change in volume of a solution on addition of a small amount of a solute B, expressed per unit mass of added solute and extrapolated to infinite dilution. The cgs unit (in which values are often listed) is $\text{cm}^3 \text{g}^{-1}$ and the SI unit is $\text{m}^3 \text{kg}^{-1}$.

particle 1 an extremely small piece or portion of (esp. solid or colloidal) matter. **2 elementary particle.** —**particulate** *adj.*

particulate enzyme any enzyme that is bound to an insoluble cellular or subcellular structure or that has been artefactually or artificially attached to particulate material.

particulate radiation any form of radiation consisting of a stream

of particles, especially alpha radiation, beta radiation, or neutron radiation emanating from a radioactive source.

partition 1 (*in chemistry*) or **distribution** the equilibration of a solute between two phases (usually of differing composition); the result of such a process. **2** (*in genetics*) the events that lead to the separation of chromosomes or to the segregation of plasmids into daughter cells in prokaryotic organisms.

partition chromatography any form of chromatography in which separation of the components of a mixture is based mainly on differences between the solubilities of the components in the stationary phase (in gas chromatography) or on differences between the solubilities of the components in the mobile and stationary phases (in liquid chromatography).

partition coefficient or **distribution coefficient** *symbol:* α or K_d ; the ratio of the equilibrium concentrations of a pure substance dissolved in two phases that are in contact, at a specified temperature. The partition coefficient is independent of the concentrations provided that no chemical interaction occurs with either (or both) of the phases and that the presence of the solute does not affect their immiscibility.

partition function *symbol:* Z ; a dimensionless mathematical function, derived by the application of statistical mechanical theory, that can be used to derive the average distribution of the internal energy of a system in terms of its partition between all its molecular inhabitants.

partition law or **distribution law** the principle that a solute, when added to a system consisting of two phases, will, at a given temperature, distribute itself between the two phases in proportion to its solubility in each of the two phases separately. **Henry's law** is a particular case of the partition law. *See also Nernst distribution law.*

partitioning (*in an ontology*) a 'parts' hierarchy into which the components of discrete objects are organized, often expressed as 'has a' relationships: e.g. apolipoprotein A has 38 kringle domains.

parturition the act or process of giving birth to offspring.

parvalbumin any of a group of closely related ~12 kDa muscle proteins that bind calcium ions. Parvalbumin α is a muscle **EF-hand** Ca^{2+} -binding protein that may be involved in muscle relaxation. Parvalbumin β is known as **oncomodulin**.

parvovirus any of a group of small, animal viruses, in class II of the **Baltimore classification**, consisting of a naked capsid, 20–25 nm in diameter, and containing linear, single-stranded DNA of 1.2–1.8 MDa. Parvoviruses are highly resistant to chemical and physical agents.

parvulin a **peptidylprolyl isomerase** isolated from *Escherichia coli*. It does not have any function as an **immunophilin**.

PAS *abbr. for 1 p-aminosalicylic acid. 2 periodic acid-Schiff; see periodic acid-Schiff reaction.*

pascal *symbol:* Pa; the SI derived unit of pressure or stress. It is equal to a force of one newton per square metre; i.e.

$$1 \text{ Pa} = 1 \text{ N m}^{-2} = 1 \text{ J m}^{-3}.$$

[After Blaise Pascal (1623–62), French mathematician and philosopher, who discovered the relationship between barometric pressure and altitude.]

PASCAL 1 *see bibliographic database. 2 see programming language.*

PAS domain a structural domain of ≈ 130 residues that occurs in proteins that respond to stimuli such as light, redox potential, O_2 , or small aromatic molecules. It is found in archaea, bacteria and eukaryotes, and named after the proteins in which they occur (period circadian protein, Ah receptor nuclear translocator protein and single-minded protein). PAS domains act as signal sensors in many signalling proteins. Several PAS domain-containing proteins detect their signal by means of an associated cofactor (e.g., haem, flavin, a 4-hydroxycinnamyl chromophore). PAS domains are often associated with PAC domains, with which they are directly linked, together forming the PAS fold. The linking region between these domains is highly divergent; in human PAS kinase, this region is flexible, adopting different conformations depending on the bound ligand.

Pasha (Partner of Drosha) a dsRNA-binding protein which interacts with **Drosha** in the **Microprocessor** complex to initiate miRNA

production in the nucleus. Also named DGCR8 (**Di George syndrome** chromosomal region 8).

passage (*in biology*) the action or process of (serially) subculturing cells or microorganisms, especially with a view to adapting them to a changed environment.

passage number (*in cell culture*) the number of subcultures performed after the original isolation of the cells from a primary source.

passenger or **passenger DNA** any specific DNA fragment introduced into a **cloning vector** or other cloning vehicle.

passive diffusion *an alternative name for simple diffusion* (used especially to emphasize its distinction from **active transport**). *Compare facilitated diffusion.*

passive immunity immunity in an individual due to the presence of antibody or primed lymphocytes derived from another, already immune, individual.

Pasteur effect or (*formerly*) **Pasteur–Meyerhof effect** either the phenomenon that occurs in facultatively anaerobic cells whereby oxygen inhibits glycolysis or fermentation, or its converse whereby the rate of glycolysis or fermentation increases when oxygen is excluded. *Compare Crabtree effect.* [After Louis Pasteur (1822–95), French chemist, microbiologist, and immunologist.]

pasteurization or **pasteurisation** a method of heat-treating milk or similar fluids to improve storage qualities and destroy pathogenic bacteria, without markedly altering taste and nutritional characteristics. Pasteurization of milk involves heating to 65°C for 30 minutes or to 72°C for 15 minutes followed by rapid cooling to below 10 °C. —**pasteurize** or **pasteurise** *vb.*

Pasteur pipette or **pasteur pipette** a simple, disposable, ungraduated, dropping or transfer pipette constructed by drawing out a short length of narrow glass tubing to form a long fine tip and operated commonly by means of an attached rubber or PVC bulb or teat. Analogous devices are available moulded in low-density polyethylene, with integral bulb and sometimes calibrated. *Also (esp. US): Pasteur pipet, pasteur pipet.*

Pasteur reaction the putative chemical reaction once considered to link fermentation and respiration and to account for the **Pasteur effect**.

patatin any of a family of glycoproteins that form 40% of the soluble protein of potato tubers. They serve as potato somatic storage proteins, and also have enzyme activity involved in host resistance. They have lipid acylhydrolase activity.

patch an intermediate stage in the formation of a **cap** (def. 2) on the surface of a cell, e.g. of a lymphocyte.

patch-clamp technique a technique whereby the conductance change of a single ion channel of an excitable membrane is measured directly. A very small electrode tip is sealed onto a patch of cell membrane, thereby making it possible to record the flow of current through individual ion channels in the patch. *See also* **Neher, Sakmann.**

Patched a human protein encoded by a homologue of the segment polarity gene *patched* of *Drosophila*. It is a multipass transmembrane receptor for **sonic hedgehog** (or Shh), with a covalently linked C-terminal cholesterol molecule and a palmitoylated N-terminal cysteine residue. Patched functions through a neighboring G-protein receptor-like protein called smoothened. In the absence of Shh, Patched inhibits smoothened and thus inhibits transcription of genes for Patched, transforming growth factor β , and Wnt proteins. The Patched gene at 9q22.3 encodes a protein of 1296 amino acids. Mutations, mostly of the nonsense variety, cause an autosomal dominant naevoid basal cell carcinoma syndrome, and are also associated with some sporadic medulloblastomas.

paternal imprinting the epigenetic silencing of an allele inherited from the father. *See* **imprinting.**

path *see* **light path.**

+pathic *see* **+pathy.**

patho+ or (*before a vowel*) **path+** *comb. form* denoting disease or clinical disorder.

pathobiochemistry **1** the study of the biochemical processes associated with disease. **2** the processes themselves.

pathogen any agent, especially any living organism, that can cause disease.

pathogenesis the generation and production, or the origin and development, of a disease. —**pathogenic** *adj.*

pathogenesis-related proteins proteins synthesized in plants in response to attack by fungal or bacterial pathogens, presumably involved in the plant defence mechanism. They belong to an evolutionarily related family of small, eukaryotic, extracellular proteins, dubbed CRISP (cysteine-rich secretory proteins).

pathogenic (capable of) causing or producing disease. —**pathogenicity** *n.*

pathogenicity island a region of a bacterial genome containing clusters of genes linked to its pathogenic behaviour. For example, the *Escherichia coli* LEE pathogenicity island contains genes for gut wall attachment. Such islands are not usually present in all strains of a given bacterial species and are thought to have been acquired by horizontal transfer.

pathological or **pathologic** **1** of, or pertaining to, pathology. **2** causing, relating to, involving, or caused by disease.

pathology **1** the branch of medical science concerned with the causes and nature of disease and with the effects of disease on the structure and functioning of the organism. **2** the sum of the changes that occur in an organism as the result of a specific disease. —**pathologist** *n.*

pathophysiology **1** the study of the physiological processes associated with disease. **2** the processes themselves.

pathway **1** the chain of reactions undergone by a given molecular entity or class of such entities in a particular ecosystem. **2** **metabolic pathway.**

pathway database a database that links gene products and compounds in the cells of an organism to components on particular pathways. Such databases are used to facilitate gene function assignment and metabolic reconstruction. Examples include: BIND, which stores information on biomolecular interactions, molecular complexes, and pathways; EcoCyc, which houses metabolic, regulation, and signal transduction data on *Escherichia coli*; KEGG (Kyoto Encyclopedia of Genes and Genomes), which links human genes with networks of interacting molecules in the cell; WIT (what is there?), which houses metabolic, gene function, and phylogenetic data from multiple genomes; and HPRD (human protein reference database), an integrated pathway database of human reference proteins that contains domain architectures, PTMs, interaction networks, and disease associations for the human proteome.

pathway engineering the use of **genetic engineering** to change either the kinetics or the products of a metabolic pathway.

+pathy *comb. form* denoting **1** feeling, sensitivity. **2** disease of a (specified) part or kind. **3** a method of treating disease. —**pathic** *adj.*

pattern or **signature** an abstract representation of conserved features of a multiple sequence alignment that can be used to provide a diagnostic signature for related sequences that share the same or similar features. Examples of patterns are a regular expression, profile, hidden Markov model (HMM), fingerprint, and block. The term is also sometimes used confusingly as a synonym for regular expression.

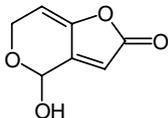

pattern database or **secondary database** or **signature database** (*in sequence analysis*) a database that houses diagnostic patterns, or signatures, usually derived from conserved regions of multiple sequence alignments of protein families or domains. Areas of conservation are encoded, for example, in the form of regular expressions, fingerprints, blocks, or hidden Markov models (HMMs). Examples of such databases include PROSITE, PRINTS, Blocks, and Pfam. They tend to include varying levels of annotation describing the protein families they encode and technical details concerning how the pattern was derived.

pattern hit initiated-BLAST *abbr.:* PHI-BLAST; *see* **database-search program.**

pattern recognition **1** (*in sequence analysis*) the recognition of characteristic patterns of conservation in sequences using some form of predefined signature or discriminator — e.g. a regular expression, fingerprint, or hidden Markov model (HMM). **2** (*in data mining*) the discovery of unknown patterns in large data sets, for example by using principal component analysis, partial least squares, or neural network approaches.

patulin 4-hydroxy-4*H*-furo[3,2-*c*]pyran-2(6*H*)-one; a carcinogenic

metabolite with antibiotic activity isolated from several fungi, particularly *Aspergillus* and *Penicillium* spp.

pauci+ *comb. form* indicating few.

paucidisperse describing a colloidal system whose dispersed phase consists of particles of only a few sizes. —**paucidispersity** *n.*

Pauli exclusion principle or **exclusion principle** or **Pauli principle** the principle that no two electrons in an atom can be described by the same set of four quantum numbers. [After Wolfgang Pauli (1900–58), Austrian-born US physicist.]

Paulus filtration method a method for studying the binding of a ligand microsoluble to a macrosolute. It is applicable to small amounts of material and is particularly useful for a system having a relatively low binding constant. It involves equilibration of a series of mixtures of macrosolute and ligand in a suitable solvent, then separation of unbound ligand from macrosolute-plus-bound-ligand by ultrafiltration through anisotropic membrane filters of an appropriate retentivity. The amount of microsoluble retained with the macrosolute on each filter is then estimated by, e.g., radioactivity measurement or another sensitive technique. [After H. Paulus.]

Pauly's reagent a chromogenic reagent for imidazoles and phenols, consisting of a freshly prepared solution of diazotized sulfanilic acid (or other aromatic amine). In the presence of alkali, this reacts with histidine to give a red colour and with tyrosine to give an orange colour. It is useful for the identification of these amino acids on paper chromatograms.

PAUP *abbr.* for phylogenetic analysis using parsimony; *see* **phylogeny package**.

Pavlovian conditioning the modification of behaviour, whereby a previously neutral stimulus becomes associated with an already existing reflex, so that it will, by itself, evoke a response. This new reflex is said to be conditional. After Ivan P. Pavlov (1849–1936), Russian physiologist and experimental psychologist, who described the effect experiments on dogs. He showed that reflex responses, like salivation, became conditional upon specific previous experiences of the animal, such as light or a tone (but probably not a bell).

Pax *abbr.* for paired box; one of a family of transcriptional regulators that contain a paired-box domain and are specifically expressed during the development of a wide range of structures and organs. There are nine *Pax* genes in mouse and in human. They are expressed primarily in the neural tube and brain in the early embryo. *Pax1* and *Pax9* are closely related, as are the groups *Pax3* and *Pax7*, and *Pax2*, *Pax5*, and *Pax8*. PAX2 protein (392 amino acids) is also expressed in the eye and kidney; mutations cause the renal-coloboma syndrome. PAX3 (836 amino acids) controls MyoD expression in limb buds; numerous mutations cause Waardenburg syndrome. PAX6 (422 amino acids) is identical in sequence in mouse and in human, and contains a homeobox domain and a C-terminal region rich in proline, serine, and threonine. It is also expressed in eye and pancreatic islet cells. Numerous mutations cause aniridia. PAX8 is implicated in embryonic development of the thyroid gland; mutations cause thyroid dysgenesis and congenital hypothyroidism.

paaxillin an adhesion protein, associated with **vinculin**, that becomes phosphorylated in response to a number of stimuli, phosphorylation being associated with focal adhesion. It is also associated with dysfunction of **cadherin**-dependent cell-cell contacts, and cell spreading.

Pb *symbol* for lead.

PBD *see* **biphenylphenyloxadiazole**.

PBG *abbr.* for porphobilinogen.

PBI *abbr.* for protein-bound iodine.

pBluescript a *proprietary name* for a phagemid cloning vector incorporating the bacteriophage $\phi 1$ origin of replication. It has 21

unique restriction sites in a multiple cloning sequence (MCS) flanked by promoters for T3 and T7 RNA polymerases.

P body *abbr.* for processing body; any of a few discrete cytoplasmic foci in yeast cells that contain proteins that activate or catalyse decapping of mRNA, mRNA degradation products, and a 5'→3' mRNA exonuclease. P bodies are essential for metabolism of mRNA and are also present in mammalian cells.

PBP *abbr.* for penicillin-binding protein.

pBR322 a **cloning vector**.

PBS *abbr.* for phosphate-buffered saline.

PC *abbr.* for 1 paper chromatography. 2 phosphocreatine. 3 phosphatidylcholine. 4 personal computer.

pCa *symbol* for the negative logarithm of the concentration (or strictly the activity) of calcium ions in a specified solution.

PCA *abbr.* for perchloric acid.

P-cadherin placental **cadherin**.

PCAF *abbr.* for p300/CBP-associated factor; a **histone acetyltransferase** that associates with p300/CBP and acetylates lysine residues in the N-terminal region of histone H3 and H4.

PCB *abbr.* for 1 pyruvate carboxylase. 2 polychlorinated biphenyl.

p300/CBP-associated factor *see* **PCAF**.

PCCase *abbr.* for propionyl-CoA carboxylase.

pCDNA 3.1 a *proprietary* vector designed for the expression of genes in mammalian cells using the cytomegalovirus promoter. It has the SV40 origin of replication and carries the gene for neomycin resistance (neo^R).

P cluster an iron-sulfur cluster, comprising a [4Fe-4S] cluster linked to a [4Fe-3S] cluster, that is present in each $\alpha\beta$ dimer of component 1 of nitrogenase.

PCM1 or **pericentriolar material** a protein of the **centrosome** that recruits centrin, pericentrin, ninein, and dyactin just before centrosomal duplication.

PCMB *abbr.* for *p*-chloromercuribenzoate, or *p*-chloromercuribenzoic acid.

PCMS *abbr.* for *p*-chloromercuribenzenesulfonate, or *p*-chloromercuribenzenesulfonic acid.

pCMV-Script a *proprietary name* for a phagemid vector designed for the expression of proteins in mammalian cells under the control of the cytomegalovirus immediate early promoter. It has both Col E1 and SV40 origins of replication and confers resistance to neomycin and kanamycin.

pCMV-SPORT any of a series of *proprietary* phagemid vectors used for expression of proteins in mammalian cells under the control of the cytomegalovirus promoter. The multiple cloning sequence is flanked by T7 and SP6 promoters.

PCNA *abbr.* for proliferating cell nuclear antigen; *other names*: processivity clamp; sliding clamp. A protein subunit (261 amino acids) of prokaryotic **DNA polymerase- δ** . It forms a homotrimer that surrounds DNA and functions as a sliding clamp in a **replisome**. Each subunit contains two similar structural domains – each consisting of a beta sandwich and two alpha helices at the inner edge – that interact with DNA. The structure is very similar to that of the β subunit of the *E. coli* DNA polymerase III holoenzyme. PCNA is also required in the gap-filling step of DNA synthesis in nucleotide excision repair. It binds and is inhibited by p21.

PCP *abbr.* for 1-(1-phenylcyclohexyl)piperidine (*see* **phencyclidine**).

PCR *abbr.* for polymerase chain reaction.

p.d. *abbr.* for (electric) potential difference.

Pd *symbol* for palladium.

PDB *abbr.* for protein data bank; *see* **structure database**.

PDBj *abbr.* for protein data bank Japan; *see* **structure database**.

PDBsum *abbr.* for protein data bank summary; *see* **specialist database**.

PDBu *abbr.* for phorbol 12,13-dibutyrate, a **phorbol ester**.

PDD *abbr.* for phorbol 12,13-didecanoate, a **phorbol ester**.

PD-ECGF *abbr.* for platelet-derived endothelial cell growth factor.

PDGF *abbr.* for platelet-derived growth factor.

PDI *abbr.* for protein disulfide isomerase.

pDNA *abbr.* for plasmid DNA.

P domain or **trefoil domain** a domain of highly conserved cysteine residues, disulfide-bonded in the pattern 1–5, 2–4, 3–6, associated

with highly conserved alanine, glycine, and tryptophan residues. Such domains are found in secretory polypeptides from animals.

PDS *abbr.* for postsynaptic density.

Pdx1 *abbr.* for pancreatic duodenal homeobox 1; a mammalian homologue of a homeobox gene first described in *Xenopus*. It is expressed in all pancreatic cell types during early development, but only in pancreatic islet B cells and duodenal mucosa in adults. The protein activates promoters of insulin and somatostatin genes. Homozygous gene knockout in mice leads to neonatal death and lack of a pancreas.

PDZ domain a common homologous sequence of ~90 amino acid residues that was first detected in mammalian postsynaptic protein (PSD-95), *Drosophila* discs-large (Dlg), and mammalian tight junction protein (ZO-1), from which the acronym is derived. It forms a beta-sandwich containing 5–6 beta strands and two alpha helices and binds C-terminal protein sequences. From 1 to 13 copies may be present in a protein.

Pe *symbol* for the pentyl group.

PE *abbr.* for 1 phosphatidylethanolamine. 2 potential energy.

peak 1 a sharp increase followed by a sharp decrease in a physical quantity that varies with distance, frequency, time, etc. 2 (*in chromatography*) the portion of a differential chromatogram recording the changes in detector response or eluate concentration while a given component of the applied mixture emerges from a chromatographic column. 3 the maximum value of a **peak** (def. 1, 2).

PEC₅₀ *see* p[A]₅₀.

PEC-60 a 60-amino-acid regulatory polypeptide abundant in intestinal tissue and also found in the central nervous system. It inhibits the formation of cyclic AMP and activates Na⁺,K⁺-ATPase. It is structurally related to pancreatic trypsin inhibitor and inhibits insulin secretion.

PECAM *abbr.* for platelet endothelial cell adhesion molecule; a class of **adhesion molecules** represented by PECAM-1 (*or* CD31), a member of the immunoglobulin superfamily. It is constitutively expressed on endothelial cells, platelets, granulocytes, monocytes, and T cells, and participates in homophilic binding (*i.e.* binding to itself). It is required for transmigration of leukocytes across the endothelium during extravasation.

pectate any salt or ester of **pectic acid**.

pectic acid the form of **pectin** (def. 1) that is essentially free of methyl ester groups.

pectic substance *an alternative name for pectin* (def. 1).

pectin 1 *or* **pectic substance** any mixture of complex, colloidal, macromolecular plant **galacturonans** containing a large proportion of D-galactopyranosyluronic acid residues in (α 1→4) linkage, the carboxyl groups of which may be esterified to varying degrees by methyl groups or be partially or completely converted to salts; some D-arabinose and D-galactose residues are present, and other sugars are sometimes present. M_r is usually in the range 1×10^4 – 4×10^5 . Pectins are important matrix polysaccharides of plant cell walls, especially those of higher plants, sometimes constituting as much as one-third of the dry matter; they also occur in some plant juices. Certain fruits are particularly rich in pectin. 2 (*in commerce*) a whitish, water-soluble powder prepared from the rind of citrus fruits or apple **pomace** by extraction with dilute acid and consisting essentially of **pectin** (def. 1). It is used *inter alia* in the preparation of jams because of its ability to form gels in the presence of sucrose at high concentrations.

pectinase *see* polygalacturonase.

pectinesterase EC 3.1.1.11; *other names*: pectin methylsterase, pectin methoxylase; an enzyme that hydrolyses pectin to methanol and **pectic acid**. Found in plant cell walls, it may be concerned with cell-wall metabolism during fruit ripening.

pectinic acid the form of **pectin** (def. 1) in which a high proportion of the carboxyl groups are esterified with methanol.

pectin lyase EC 4.2.2.10; an enzyme that catalyses a *trans* elimination to convert pectin to oligosaccharides with unsaturated (C-4, C-5) terminal residues. Although often described as 4-deoxy-6-methyl- α -D-galact-4-enuronosyl groups, they are more accurately termed 4-deoxy-6-methyl- β -L-threo-hex-4-enopyranouronosyl groups.

pectin sugar *an old name for* L-arabinose.

pedigree the biological relationships of the members of a family often extending over several generations. In medical genetics it consists of a diagram of a family history showing the status of individuals with respect to a particular hereditary condition.

PEG *abbr.* for polyethylene glycol.

PEGylation *or* **pegylation** the process of modifying a protein by treatment with polyethylene glycol (PEG). *Compare* **PIGylation**.

PEI *abbr.* for the poly(ethyleneimine) group.

pelargonate *another name for nonanoate*.

pelargonidin *see* anthocyanidin.

pelargonoyl *another name for nonanoyl*.

pellagra a disease of animals, including humans, arising from a dietary deficiency of **nicotinic acid**, especially in the absence of sufficient dietary tryptophan to generate adequate amounts of nicotinamide coenzymes metabolically. This situation can occur when the diet consists largely of maize (corn). Pellagra is characterized by scaly dermatitis on exposed skin surfaces, diarrhoea, and depression.

pellagra-preventative factor *abbr.*: PP factor *or* PPF; *a former name for* **nicotinic acid** or nicotinamide.

pellet a small compressed mass of material, especially such a mass deposited at the bottom of a tube by centrifugation of a suspension.

pellicle a thin skin, membrane, or film.

pellicular 1 of, relating to, or being in the form of a pellicle. 2 describing a type of column packing, used in high-pressure liquid chromatography, in which the stationary phase is present as a thin layer on the surface of tiny glass beads.

Peltier effect the phenomenon whereby heat is given out, or absorbed, when an electric current passes across a junction between two dissimilar materials. *See* **thermocouple**. *Compare* **Seebeck effect**. [After Jean Peltier (1785–1845), French physicist.]

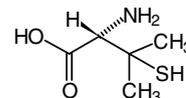

penatin *an obsolete name for* glucose oxidase.

pendrin *an alternative name for* iodide-chloride transporter.

penetrance (*in genetics*) the degree to which a particular genotype is expressed as the phenotype. If every individual carrying a dominant mutant gene shows the mutant phenotype, the gene is said to show complete penetrance. Penetrance can be related to age so that the mutant allele might show low penetrance in the young but increasing penetrance in older individuals.

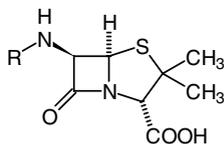

penetratin *or* **Trojan peptide** a natural or synthetic polypeptide that is rich in basic amino acids and mediates uptake of nucleic acids, bioactive peptides, phage particles, and liposomes into mammalian cells. Examples include the HIV Tat protein and *Drosophila* Antennapedia protein.

penicillamine 3-mercapto-D-valine; β , β -dimethylcysteine; 2-amino-3-methyl-3-mercaptopropanoic acid; the D-enantiomer is a characteristic degradation product of penicillin-type antibiotics. A potent chelator of heavy metal ions, it is used clinically in the treatment of **Wilson's disease** and of poisoning by metals such as copper, lead, and mercury.

penicillic acid 3-methoxy-5-methyl-4-oxo-2,5-hexadienoic acid (exists in equilibrium with lactone form); a toxic antibiotic metabolite obtained from several fungi. It bears no relationship to penicillin or its degradation products. (Illustrated opposite.)

penicillin 1 *the generic name for* a range of related antibiotics, whether produced naturally during the growth of various microfungi of the genera *Penicillium* and *Aspergillus* or of semisynthetic origin, that contain the condensed β -lactam–thiazolidine ring system:

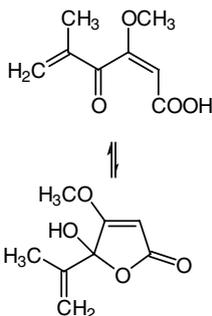

where R is any of a variety of acyl groups such as: phenylacetyl, $C_6H_5-CH_2-CO-$ (in **penicillin G**, **penicillin II**, **benzylpenicillin**); phenoxyacetyl, $C_6H_5-O-CH_2-CO-$ (in **penicillin V**); and D-adipyl, $HOOC-CH(NH_2)-[CH_2]_3-CO-$ (in **penicillin N**, also called **cephalosporin N**). Only those enantiomers having the D-configuration at C-2 of the thiazolidine ring show antibiotic activity. The parent substance, **6-aminopenicillanic acid**, in which R is H, has little intrinsic antibiotic activity but is the naturally occurring substrate for the semisynthesis of artificial penicillins, e.g. **ampicillin**, in which R is aminophenylacetyl, $C_6H_5-CH(NH_2)-CO-$. All penicillins are readily inactivated by chemical or enzymic hydrolysis of the strained four-membered β -lactam ring, cold dilute acid yielding **penicillamine**, and alkali or penicillinases and other β -lactamases forming the corresponding substituted **penicilloic acids**. The penicillins generally have extremely low toxicity to animals and high antibacterial activity, especially against Gram-positive organisms, the spectrum of activity varying somewhat with the nature of the group R. They inhibit cross-linking of peptidoglycan in the cell wall of growing bacterial cells, and render the cells sensitive to osmotic lysis. **2** the (hypothetical) substance 6-formamidopenicillanic acid, used only in combination in trivial names of certain **penicillins** (def. 1), e.g. benzylpenicillin.

penicillin acylase EC 3.5.1.11; *recommended name*: penicillin amidase; an enzyme that catalyses the hydrolysis of penicillin to a fatty-acid anion and 6-aminopenicillinate. Several enzymes differ in specificity for the fatty acid. For example, **penicillin V acylase** (or penicillin V amidase) is a homotetramer of 338 amino acids from *Bacillus sphaericus*. **Penicillin G acylase** (or penicillin G amidohydrolase) from *Escherichia coli* consists of 846 amino acids. This forms a periplasmic protein that consists of α and β subunits, representing residues 27–235 and 290–846, respectively. *See also* **6-aminopenicillanic acid**.

penicillin amidase *the recommended name for penicillin acylase*.

penicillinase *a trivial name for any β -lactamase that acts preferentially on penicillins.*

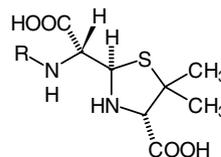

penicillin-binding protein *abbr.*: PBP; any of various bacterial proteins that are capable of binding penicillin(s) covalently. Such proteins appear to be located predominantly, if not solely, in the cytoplasmic membrane of all species of bacteria in which peptidoglycan occurs in the cell wall. These proteins are believed to catalyse reactions in the later stages of cell-wall synthesis, and there is a strong presumption that at least one of them catalyses the insertion of nascent peptidoglycan into the cell wall. In Gram-negative bacteria, some penicillin-binding proteins are known to be involved in the maintenance of cell shape or in cell elongation or septation. The

low molecular weight penicillin-binding proteins belong to a family of serine-type D-alanyl-D-alanine carboxypeptidases.

penicillin G acylase *see penicillin acylase*.

penicillin V acylase *see penicillin acylase*.

penicilloic acid any compound of structure:

and produced by cleavage of the β -lactam ring of **penicillins** (def. 1) by enzymic or alkaline hydrolysis.

pena+ *or (before a vowel) pent+* *comb. form* denoting five, fivefold, five times.

pentacos+ *comb. form* denoting 25, 25-fold, 25 times.

pentadeca+ *comb. form* denoting 15, 15-fold, 15 times.

pentafunctional arom polypeptide a polypeptide that catalyses five consecutive enzymatic reactions in prechorismate polyaromatic amino-acid biosynthesis, i.e. the second to sixth steps in the biosynthesis from chorismate of the aromatic amino acids (the **shikimate pathway**). It occurs in some yeasts and other fungi and in *Euglena gracilis*. It contains: **3-dehydroquininate synthase**, **3-dehydroquininate dehydratase**, **shikimate 5-dehydrogenase**, **shikimate kinase**, and **EPSP synthase**. In yeast the complete protein consists of 1588 amino acids; residues 1–392 = 3-dehydroquininate synthase; residues 404–866 = EPSP synthase; residues 887–1060 = shikimate kinase; residues 1061–1293 = 3-dehydroquininate dehydrogenase; and residues 1306–1588 = shikimate dehydrogenase.

pentagastrin *the trivial name for (N-tert-butylloxycarbonyl- β -alanyl)-L-tryptophanyl-L-methionyl-L-aspartyl-L-phenylalaninamide*; a synthetic analogue of **gastrin** that consists of the latter's C-terminal tetrapeptide amide sequence with an added protected N-terminal β -alanyl residue. It is used in the **pentagastrin test** as a gastrin analogue to stimulate gastric-acid secretion, which is then measured. The test results are too variable to be of great use in diagnosis. *See also* **calcitonin**.

pentakisphosphate *see multiplying prefix*.

pentamer 1 any oligomer consisting of or derived from five monomers. **2** the group of five capsomeres in an icosahedral virus capsid.

pentanoate *another name for valerate*.

pentanoyl *another name for valeryl*.

pentose a pentasaccharide in which all the residues are of one type and uniform linkage. *Compare* **pentose**.

pentaric acid any **aldaric acid** obtained by oxidation of a **pentose** at C-1 and C-5.

pentasaccharide any oligosaccharide composed of five monosaccharide units. Pentasaccharides occur in small amounts in plants, e.g. **verbascose** in soybeans.

penta-snRNP the preassembled **spliceosome** complex that contains the five small nuclear RNAs (snRNA).

pentatricopeptide repeat a peptide of 35 amino acids found in multiple copies in some proteins. Their function is unknown but might be involved with RNA stabilization. The repeat seems to be greatly expanded in plants.

pentaxin *or* **pentraxin** any of a family of proteins with a discoid appearance under electron microscopy, having five non-covalently bound subunits. The family includes **C-reactive protein**, serum amyloid P-component, and neuronal pentaxins.

pentitol any **alditol** having a chain of five carbon atoms in the molecule.

pentobarbital 5-ethyl-5-(1-methylbutyl)barbiturate; a major barbiturate drug. *One proprietary name* is Nembutal.

pentolinium test a test in which **pentolinium**, a sympathetic ganglion blocking drug, is used to reduce catecholamine secretion; failure to achieve reduction may indicate a **pheochromocytoma**.

penton a capsomere that is surrounded by five other capsomeres in an icosahedral virus capsid.

pentonic acid any monocarboxylic acid (aldonic acid) formally derived from a pentose by oxidation at C-1.

pentosan a **glycan** that yields only pentoses on hydrolysis.

pentose any **aldose** having a chain of five carbon atoms in the molecule. *Compare* **pentose**.

pentose cycle an alternative name for **pentose phosphate pathway**.

pentose nucleic acid *abbr.*: PNA; a former term for **ribonucleic acid**.

pentose phosphate pathway or **hexose monophosphate pathway** a complex series of cytosolic metabolic reactions by which glucose 6-phosphate is oxidized with formation of carbon dioxide, ribulose 5-phosphate, and reduced NADP, the ribulose 5-phosphate then entering a series of reactions in which a number of sugar phosphates containing between three and seven (or eight) carbon atoms are successively interconverted. One consequence of these interconversions is the nonoxidative regeneration of glucose 6-phosphate, which then can enter the pathway for another cycle of oxidative decarboxylation and skeletal rearrangement, the eventual result being the complete oxidation of one molecule of glucose with the formation of six molecules of carbon dioxide and 12 molecules of NADPH. The pathway thus provides (in some organisms or tissues) an alternative route to (or shunt of) part of the glycolytic pathway; it also provides ribose 5-phosphate for nucleotide synthesis and (in some organisms) other intermediates for biosynthesis. Of special importance is D-erythrose 4-phosphate, required for the biosynthesis of aromatic amino acids and many other materials by the **shikimate pathway**. In higher plants many of the pathway enzymes function in the reverse direction as part of the **reductive pentose phosphate cycle**. *Other names*: hexose monophosphate shunt; pentose cycle; phosphogluconate (oxidative) pathway; Warburg–Dickens pathway; Warburg–Dickens–Horecker pathway. *See also* **glucose-6-phosphate dehydrogenase**, **phosphogluconate**, **phosphogluconate dehydrogenase** (decarboxylating), **transaldolase**, **transketolase**.

pentosuria the presence of excessive amounts of pentose in the urine. In **essential pentosuria**, daily excretion of 1–4 g L-xylulose (normal <60 mg) occurs because of deficiency of L-xylulose reductase (EC 1.1.1.10), an enzyme of the glucuronate pathway that converts L-xylulose to xylitol. In **alimentary pentosuria** excretion of up to 100 mg of L-arabinose or L-xylose occurs following ingestion of unusually large amounts of such fruits as cherries, grapes, and plums. Both forms are clinically benign.

pentraxin *see* **pentaxin**.

pentulose any **ketose** having a chain of five carbon atoms in the molecule. There are two enantiomeric pairs of pentuloses having the carbonyl group at C-2, these being the D- and L-isomers of ribulose, *erythro*-2-pentulose, and of xylulose, *threo*-2-pentulose.

pentyl *symbol*: Pe; the alkyl group, CH₃–[CH₂]₃–CH₂–, derived from pentane.

Pep-1 a synthetic 21-amino-acid peptide used experimentally for protein delivery into cells. It contains a tryptophan-rich region for hydrophobic interaction and a lysine-rich region that improves delivery and solubility of the vector. The Pep-1–protein complex dissociates on entry into a cell.

PEP *abbr.* for phosphoenolpyruvate.

PEPCK *abbr.* for phosphoenolpyruvate carboxykinase.

pepinase a pepstatin-insensitive lysosomal protease (547 amino acids) that also has carboxypeptidase activity. Deficiency of this enzyme results in a late-onset form of neuronal lipofuscinosis.

peplomer a virus-coded proteinaceous knob or spike, numbers of which project from the peplios (i.e., **envelope** (def. 3)) of an enveloped virus particle. Peplomers may have cell-receptor, hemagglutinating, or neuraminidase activity.

peplios an alternative name for **envelope** (def. 3).

pepsin I any of the closely related aspartic proteinase enzymes of 31–36 kDa that constitute the principal proteinase activity of gastric juice of vertebrates. The family includes **pepsin A**, **pepsin B**, **pepsin C** (i.e. **gastricsin**), and **pepsin D**. Pepsins have maximal activity at pH 2–3; they preferentially catalyze hydrolysis of peptide bonds formed from hydrophobic amino-acid residues, the detailed specificity varying somewhat between the different pepsins. **2** an alternative name for **pepsin A**.

pepsin A or **pepsin** the recommended name for the predominant en-

zyme (EC 3.4.23.1) of the **pepsin** family. It is a phosphoprotein (in pig, 327 amino acids) formed by limited proteolysis of pepsinogen A. It preferentially cleaves peptide bonds flanked on either side by hydrophobic amino acids; for example, in the B chain of insulin it cleaves Phe¹-|Val², Gln⁴-|His⁵, Glu¹³-|Ala¹⁴, Ala¹⁴-|Leu¹⁵, Leu¹⁵-|Tyr¹⁶, Tyr¹⁶-|Leu¹⁷, Gly²³-|Phe²⁴, Phe²⁴-|Phe²⁵, and Phe²⁵-|Tyr²⁶ bonds (*compare* **pepsin B**). The unphosphorylated form of porcine pepsin A is called pepsin D.

pepsin B or **parapepsin I** a pig enzyme (EC 3.4.23.2) of the **pepsin** family. It is a phosphoprotein (332 amino acids) formed by limited proteolysis of pepsinogen B. It has little activity towards hemoglobin as substrate (*compare* **gastricsin**), but degrades gelatin. Its specificity on the B chain of insulin is more restricted than **pepsin A**; it does not cleave Phe¹-|Val², Gln⁴-|His⁵, or Gly²³-|Phe²⁴.

pepsin C an alternative name for **gastricsin**.

pepsin D unphosphorylated pig **pepsin A**.

pepsinogen a precursor of a **pepsin** enzyme; pepsinogens A, B, and C give rise to **pepsin A**, **pepsin B**, and **pepsin C** (i.e. **gastricsin**) respectively. Pepsinogens are secreted by the chief cells of the gastric mucosa of vertebrates. Their active site is masked at neutral pH, and exposed as the pH falls after secretion into the stomach. The first bond breakage causes the release of residues 1–16, leaving **pseudopepsin**. A further 28 residues are removed in stages to form the active enzyme. Pepsinogen C is also secreted by the mucosa of the proximal duodenum. Human pepsinogen A consists of 388 amino acids; residues 63–388 are pepsin.

pepstatin A *N*-isovaleryl-L-valyl-L-valyl-3-hydroxy-6-methyl-4-aminoheptanoyl-L-alanyl-3-hydroxy-6-methyl-4-aminoheptanoic acid; a peptide, isolated from broth cultures of *Streptomyces* spp., that inhibits pepsin and other aspartic proteases, notably cathepsin D, renin, and fungal acid proteases.

peptaibophol or **peptaibol** any peptide amide antibiotic, 15–24 residues long and containing up to 40% α -aminoisobutyric acid residues. The group includes emerimicin, zervamicin IIA, anti-amoebin I, sizucacillin A, and **alamethicin**, all of which alter the permeability of phospholipid bilayers. The N termini are acylated and the C-terminal carboxyl groups are in amide linkage with phenylalaninol.

peptic 1 of, pertaining to, caused by, or containing **pepsin**. **2** of, pertaining to, or promoting digestion.

peptidase or **peptide hydrolase** or **protease** any enzyme that hydrolyses peptide bonds. The group includes the **exopeptidases**, such as the aminopeptidases and carboxypeptidases, (sub-subclasses EC 3.4.11–19) and the **endopeptidases** (sub-subclasses EC 3.4.21–99). The 1992 revision of *Enzyme Nomenclature* (published for IUBMB by Academic Press) should be consulted for more detail.

peptidase P-sites sites adjacent to or near the cleaved site in peptidase substrates; in describing the specificity of peptidases, it is useful to have a convention for identifying the residues on either side of the cleaved bond; the following model is often followed (the cleaved, or scissile bond is indicated as |-, and the N terminus is as usual to the left):

Compare **peptidyl site**.

peptide any compound containing two or more amino-acid residues joined by amide bond(s) (*see* **peptide bond**) formed from the carboxyl group of one amino acid (residue) and the amino group of the next. The term peptide usually applies to compounds in which the amide bond(s) are formed between C-1 of one α -amino acid (residue) and N-2 of another, but it includes compounds in which the residues are linked by other amide bonds. *See also* **oligopeptide**, **polypeptide**. —**peptidic** *adj.*

peptide amidation a post-translational modification in which the amido group of a glycine residue is cleaved so as to produce the amide group on the carboxyl end of the preceding residue. The reaction requires two enzymes: (1) peptidylglycine α -amidating monooxygenase (*abbr.*: PAM; EC 1.14.17.3), which is a copper-containing membrane protein that changes the glycine to a hydroxyglycine residue, in a reaction requiring O₂ and ascorbate; and (2) peptidylglycine α -amidating lyase, EC 4.3.2.5, which produces the peptidylamine and glyoxylate. Many bioactive peptides and peptide

hormones exhibit full biological activity only when their C-terminal group is amidated. *See* **thyrotropin-releasing hormone**.

peptide antibiotic any antibiotic containing amino-acid residues, some of which are often of the D-form, linked to one another by peptide bonds, to hydroxy acids by depsipeptide bonds, and frequently also to additional components; the structure is often cyclic. The group includes the **bacitracins**, **gramicidins**, **polymyxins**, and **tyrocidins**.

peptide bond or **peptide linkage** any amide bond formed between two amino acids (or amino-acid residues). The term usually denotes the amide bond (sometimes called the **europeptide bond**) formed between an α -amino group of one amino acid and an α -carboxyl group of another amino acid, but it also includes any amide bond (sometimes called an **isopeptide bond**) formed from an amino group and a carboxyl group, either or both of which are in other positions in the contributing amino acids. The peptide bond is planar. *See also* **Ramachandran plot**.

peptide chain or **polypeptide chain** any discrete linear sequence of amino-acid residues linked by europeptide bonds, especially in a larger molecular structure. *See* **peptide bond**.

peptide HI *abbr.*: PHI; *other name*: PHI-27; a 27-residue peptide amide found in intestinal tissue, brain, respiratory tract, and pancreas. It stimulates insulin and pancreatic exocrine secretion, causes vasodilation, increases intestinal fluid transport, relaxes smooth muscle, and is a potent prolactin-releasing factor. It shows sequence homology with gastric inhibitory polypeptide, glucagon, secretin, and vasoactive intestinal polypeptide; human PHI has the sequence

(porcine PHI has Arg¹² and Ile²⁷; bovine has Tyr¹⁰, Arg¹², and Ile²⁷). It is named for the histidine and isoleucine residues (single-letter codes H and I) at the N and C termini, respectively, of the porcine and bovine peptides.

peptide histidine valine 42 *abbr.*: PHV 42; a peptide with N-terminal histidine and C-terminal valine, derived from residues 81–122 of prepro-vasoactive intestinal peptide.

peptide hormone or **polypeptide hormone** any peptide with hormonal activity in animals, whether endocrine, neuroendocrine, or paracrine. Such substances form a very diverse group physiologically, and the boundary between peptide hormones and protein hormones is somewhat indistinct.

peptide hydrolase *another name for* **peptidase**.

peptide library an assembly of peptides with different sequences, that have many applications in testing for interactions with proteins such as antibodies, peptidases, and protein kinases, nucleic acids, or other ligands. The peptides may be synthesised by combinatorial chemistry, or by phage display. They are typically arranged in an array for testing with fluorescent markers. Applications include epitope mapping, bioactivity screening, and other biochemical studies.

peptide linkage 1 *an alternative name for* **peptide bond**. **2** chemical linkage between structural components of a molecule by means of peptide bonds.

peptide map a pattern, characteristic of a particular polypeptide or protein, produced by partial hydrolysis, followed by two-dimensional fractionation of the resultant peptides (and amino acids) by chromatography and/or electrophoresis.

peptide nucleic acid a synthetic DNA analogue with an *N*-(2-aminoethyl)glycine backbone that mimics DNA in forming a **heteroduplex**.

peptidergic 1 describing any nerve that is activated by a peptide agonist. **2** describing any nerve that acts by releasing a peptide agonist from its nerve endings, whether into a synapse with another neuron, into intercellular fluid, or directly into the bloodstream.

peptide synthesis 1 (*in biology*) *see* **protein and peptide biosynthesis**. **2** (*in chemistry*) the synthesis, by chemical means, of peptides. The first step is the protection, in the amino-acid reactants, of reactive groups not involved in peptide bond formation (*see* **protecting groups**); peptide-bond formation is then achieved by activation of the carboxyl group, which is reacted with the free α -amino group of another amino acid. A method frequently used for activation of the

carboxyl group is to react it with *N*-hydroxysuccinimide or a derivative to form an acyl succinimide ester, which reacts under mild conditions with free amino groups. Normally, and always in automated methods, the carboxyl group of the first amino acid is attached to a resin, by a bond that is easily detached later, so that the desired product, the growing peptide chain, remains attached to the resin which facilitates its purification; this technique, called **solid-phase peptide synthesis**, was pioneered by **Merrifield**.

peptide unit (*in crystallography*) any sequence of atoms in a peptide chain that may be represented by the general formula $-\text{CHR}-\text{CO}-\text{NH}-$, where R denotes the side chain of an amino-acid residue. *Compare* **amino-acid residue**.

peptide YY *abbr.*: PYY; a 36-residue peptide amide originally found in porcine upper small intestinal tissue. It is a gut hormone that inhibits exocrine pancreatic secretion. Members of this family regulate numerous physiological processes, including appetite, gastrointestinal transit, anxiety, and blood pressure. It shares sequence similarity with **neurotensin** and **pancreatic hormone**, having the amino-acid sequence:

It is named after the single-letter code, Y, for the tyrosine residue at its N terminus and the tyrosine amide at its C terminus.

peptido+ *comb. form* indicating the presence of peptide linked to some other (specified) component(s).

peptidoglycan or **murein** any glycoconjugate found only in bacterial cell walls and consisting of strands of glycosaminoglycan cross-linked by oligopeptides to form a huge and rigid network. There are characteristic differences between peptidoglycans of eubacteria and those of archaeobacteria. The glycosaminoglycan strands are formed of alternating residues, usually *N*-acetylated or *N*-glycoloylated, of D-glucosamine and either muramic acid (in Bacteria) or L-talosaminouronic acid (in archaea); the carboxyl groups of the muramic-acid residues are commonly joined in amide linkage to oligopeptides containing residues of both L- and D-amino acids whereas those of the L-talosaminouronic-acid residues are linked to peptides consisting of L-amino acids only. The peptide side-chains of adjacent polysaccharide strands are sometimes crosslinked between a carboxyl group of one peptide moiety and an amino group of another, either directly by a peptide bond or indirectly by an interpeptide bridge consisting of one to several amino-acid residues.

peptidomimetic describing a substance that imitates a peptide. It is used of drugs (e.g. ritonavir and saquinavir) that inhibit HIV protease because they resemble its natural substrate.

peptidyl the acyl group formed from a peptide by removal of the hydroxyl group from its C-terminal carboxyl group.

peptidylglycine α -amidating monooxygenase *abbr.*: PAM. *See* **peptide amidation**.

peptidyl α -hydroxyglycine α -amidating lyase an enzyme of the Golgi complex that catalyses the conversion in a polypeptide of an α -hydroxyglycine residue into a peptidyl amine and glyoxylate. This is the second reaction of C-terminal **peptide amidation**.

peptidylprolyl isomerase *abbr.*: PPIase; EC 5.2.1.8; *systematic name*: peptidylproline *cis-trans*-isomerase; an enzyme that irreversibly converts prolyl residues within a polypeptide chain from a *trans* to a *cis* configuration. It accelerates protein folding. At least two families are known. One is identical to **cyclophilin**. Another class of immunophilins that exhibit isomerase activity are the FK506-binding proteins (*see* **FKBP**). The physiological role of these proteins is unresolved. The peptide Ala-Pro inhibits the reaction.

peptidyl site or **P-site** or (*more correctly*) **peptidyl-tRNA site** the ribosomal site to which a newly elongated peptidyl-tRNA molecule is transferred from the aminoacyl site during the sequence of polypeptide biosynthesis reactions, and at which it displaces the tRNA molecule remaining from the previous elongation step. *Compare* **peptidase P-site**. *See also* **ribosome**.

peptidyltransferase EC 2.3.2.12; the ribosomal enzyme that catalyses the elongation step in polypeptide synthesis:

It is an activity of the large ribosomal subunit involving, in bacteria,

ribosomal proteins L2, L3, L4, L15, and L16, and especially 23S rRNA, which is therefore a ribozyme. The activity of the 23S rRNA is removed by ricin. *See also* **peptidyl site**.

peptidyl-tRNA the form in which a growing polypeptide chain is held to a ribosome during polypeptide biosynthesis. The polypeptide is esterified through its C-terminal carboxyl group to the 3'-hydroxyl of the adenosine residue at the 3' end of a tRNA. *See* **protein synthesis**.

peptize or **peptise** to disperse (an aggregate) to form a colloidal stable suspension or emulsion; especially to convert (a gel) into a sol. —**peptization** or **peptisation** *n*.

peptolide (*sometimes*) any naturally occurring cyclodepsipeptide; *see* **depsipeptide**.

peptone any soluble mixture of products, 0.6–3 kDa, of the partial enzymic (or acid) hydrolysis of proteinaceous material. It is used as a constituent of many microbiological culture media.

peptonize or **peptonise** 1 to convert (proteinaceous material) into **peptone**. 2 to combine with peptone; e.g., peptonized iron. —**peptonization** or **peptonisation** *n*.

per+ *comb. form* denoting 1 through, throughout, beyond; e.g. perennial. 2 (*in chemistry*) a (of an indicated element) being in a higher than usual state of oxidation; e.g. periodate. *See also* **peracid** (def. 1). b containing a higher than normal proportion of (an indicated element); e.g. **peroxide**. *See also* **peroxoacid**, **peroxy acid** (in the trivial names performic, peracetic, and perbenzoic acids) **peroxy+**. d exhaustive replacement of hydrogen (except any in a characteristic group) in an organic compound by (an indicated halogen); e.g. perfluoropentane, C₅F₁₂. *See also* **perhydro**.

PER *abbr. for period*.

peracid or **per-acid** 1 a common name for any inorganic acid in which the central element of the acid is in its highest state of oxidation. 2 a common name for **peroxoacid**. 3 a common name for **peroxy acid**.

per cent or **percent** *symbol*: %; containing or consisting of a specified numerical proportion (of some component in relation to a whole) expressed as a number fraction multiplied by 100; bearing a specified numerical relationship (to some quantity) similarly expressed. When the term per cent or the symbol % is applied to a solution, one of the designations w/w, w/v, or v/v may be appended according as the units used are mass per mass, mass per volume, or volume per volume, respectively.

percentage proportionality expressed per cent; it is used especially to qualify a substantive, e.g. percentage error.

perchloric acid *abbr.*: PCA; chloric(vii) acid, HClO₄; a compound used in chemical analysis as an oxidizing agent.

Percoll *the proprietary name for* a polydisperse preparation of colloidal silica particles rendered nontoxic to cells by a coating of polyvinylpyrrolidone. Aqueous dispersions of the material can be used to generate density gradients for the separation of cells, viruses, or cell organelles by sedimentation.

percutaneous through the skin; used especially of the route of administration of drugs applied to the skin.

perforin a lymphocyte pore-forming protein; it is produced by cytotoxic T cells when these are in contact with target cells, being stored in secretory vesicles, and released by local exocytosis. With Ca²⁺, it polymerizes into transmembrane tubules that form pores in the target-cell membrane, and is thus capable of lysing non-specifically a variety of target cells.

performic acid *the trivial name for* peroxyformic acid, H–C(=O)–O–OH; a strong oxidizing agent, useful in protein chemistry for cleavage of any disulfide bond, R–S–S–R', to the corresponding pair of sulfonic acid groups, R–SO₃H + R'–SO₃H, e.g. of a cystine residue to two cysteic-acid residues. Tryptophan residues are also oxidized, and methionine residues are converted to methionine S,S-dioxide residues.

perfusate any fluid used for a perfusion.

perfuse to pass fluid through an organ or tissue, especially artificially. —**perfusion** *n*.

perhydro+ *prefix (in chemical nomenclature)* signifying conversion of the indicated unsaturated organic compound to the corresponding fully hydrogenated compound; used especially where the parent

compound is markedly unsaturated; e.g. perhydroanthracene, C₁₄H₂₄ (formed from anthracene, C₁₄H₁₀).

per+ *comb. form* enclosing, surrounding; near.

periaxin a PDZ domain-containing protein that when mutated causes a severe demyelinating peripheral neuropathy called Dejerine–Sottas syndrome.

pericellular surrounding a cell or cells.

pericentric describing an inversion of part of a chromosome that spans the centromere, with breakpoints in both the arms. *Compare* **paracentric**.

pericentrin *see centrosome*.

pericentriolar material *see PCM1*.

perifusate any fluid used for a perfusion (*see* **perifuse**).

perifuse to pass a fluid around isolated cells or cell clusters in suspension. —**perifusion** *n*.

peri-fused *see ortho- and peri-fused*.

perikaryon or **cell body** the cytoplasm immediately surrounding the nucleus of a neuron.

perilipin a protein found in adipocytes, exclusively at the surface of the lipid storage droplets that serves as the major A-kinase substrate. It is a major hormonally regulated adipocyte-specific phosphoprotein.

perinuclear space the zone, 20–40 nm wide, between the two lipid bilayers of the **nuclear envelope** of a eukaryotic cell.

period 1 a specified or defined length of time, especially the time occupied by one complete cycle of some regularly recurring phenomenon or event. 2 (*in chemistry*) any of the horizontal rows of chemical elements in the **periodic table**. 3 *abbr.*: PER; either of two **PAS domain**-containing proteins (PER1 and PER2) involved in regulating circadian rhythms. They are induced by the clock-BMAL1 dimer in the suprachiasmatic nucleus in hypothalamus, and by the NPAS2-BMAL1 dimer in forebrain nuclei. Their activity is regulated by a protein-serine/threonine kinase, and they act as negative regulators of the circadian control system, which was discovered in *Drosophila* mutants with abnormal circadian cycles. Homologues occur in other organisms including humans. *See also* **BMAL1**, **clock**, **NPAS2**.

periodate 1 any anion derived from a **periodic acid**, especially the anion, IO₄, derived from metaperiodic acid. 2 any salt of a periodic acid, especially of metaperiodic acid or orthoperiodic acid.

periodate oxidation a method for the investigation of the structure of organic molecules, based upon the ability of aqueous periodate (or periodic acid) to cleave specifically and quantitatively any carbon-carbon single bond where one carbon atom carries a hydroxyl group and the other carries an amino, carbonyl, carboxyl, or hydroxyl group, these groups being oxidized and the periodate reduced to iodate. The method is particularly useful in the structural analysis of carbohydrates. *See also* **periodic acid-Schiff reaction**.

periodic 1 of, relating to, or resembling a **period** (def. 1 or 2); happening or occurring in periods; intermittent; cyclical. 2 (*in chemistry*) denoting any of several oxoacids of iodine containing a greater proportion of oxygen than iodic acid. *See* **per+** (def. 2a), **periodic acid**. — **periodically** *adv*.

periodic acid any of a number of iodic(vii) acids formed by the combination of iodine heptoxide, I₂O₇, with water in different molecular proportions, especially **orthoperiodic acid** (formerly known as paraperiodic acid), H₅IO₆; **metaperiodic acid**, HIO₄, exists mainly as its salts. These acids and their salts are strong oxidizing agents.

periodic acid-Schiff reaction *abbr.*: PAS reaction; a chromogenic reaction used as a sensitive test for carbohydrate, either histochemically or in chromatography. It is based on the periodate oxidation of *vicinal*-CHOH-groups to -CHO groups and the subsequent reaction of these with **Schiff reagent** to give a characteristic magenta colour.

periodic classification *see* **periodic system**.

periodicity the recurrence (of some phenomenon or event) at constant intervals in space or time; a measure of the frequency of such recurrence.

periodic law or **Mendeleev's law** the principle that the properties of the chemical elements are a periodic function of their atomic numbers (originally, of their atomic weights).

periodic system or **periodic classification** any classification of the chemical elements on the basis of the **periodic law**.

periodic table a mode of representing the **periodic system**; it is a tabular arrangement of the chemical elements in horizontal rows and vertical columns in order of increasing proton number row by row, each row, or **period**, consisting of those elements from an alkali metal to the rare gas of next highest proton number (except for the last, incomplete, period) and each column, or **group**, consisting of a family or set of those elements with similar chemical properties. Over the years, numerous versions of such a tabular arrangement have been proposed and used, the three commonest formats having 8, 18, or 32 columns of elements. Of these, the ones most widely adopted latterly have been variations of the so-called long periodic table, in which there are 18 columns. The particular version of the long table illustrated on the endpapers is the one currently recommended by IUPAC and adopted for use elsewhere in this dictionary. In this IUPAC periodic table, as similarly in other versions of the long table, the 15 elements of proton numbers 57 to 71, the **lanthanoids**, occupy a single position in period 6 of group 3, and those of numbers 89 to 103, the **actinoids**, a single position in period 7 of group 3, practical considerations requiring these elements to be listed separately at the bottom of the table.

In previous versions of the long table it was usual for 14 of the columns to be formed into seven groups, numbered I to VII and each divided into A and B subgroups. However, these subgroup designations were not always applied the same way round, with the consequence that two alternative conventions for the long table have concurrently had widespread support – one commonly in Europe (and hitherto followed in principle by IUPAC), the other in North America and elsewhere. Furthermore, the three columns containing the elements iron, cobalt, and nickel, originally designated together as group VIII, and the eighteenth column, containing the noble gases and originally designated as group O, have sometimes been labelled group VIIIA and group VIIB respectively in the European version of the table, whereas in the North-American version the noble gases have in recent years been assigned usually to group VIIIA. The resultant confusion led IUPAC to recommend in 1990 that the columns of the long periodic table now be serially numbered as groups 1 to 18. The correspondence of the group designations in the new IUPAC periodic table with those of the European and North-American conventions in recent use is also shown in the endpapers.

peripheral (cell-membrane) protein or **extrinsic protein** an *operational term* for any protein that can be dissociated unchanged from a cell membrane by a mild treatment, such as increase in ionic strength of the medium, or addition of a chelating agent to it. Such proteins are presumed to be loosely attached to one or other surface of the cell membrane. *Compare* **integral (cell-membrane) protein**.

peripheral nervous system the part of an animal's nervous system other than the **central nervous system**, and generally located in the peripheral, or outer, parts of the body. It comprises the cranial nerves and spinal nerves and their branches, and includes the **autonomic nervous system**. It serves to link effector organs and sensory receptors with the central nervous system.

peripherin a glycoprotein, named from 'peripheral vision', that is essential for eye-disk morphogenesis; it is probably an adhesion molecule. Dysfunctional forms of peripherin precipitate retinopathies such as **retinitis pigmentosa**.

peripherin/RDS *see* **peripherin**.

periplasm or **periplasmic space** the region in a bacterial cell between the cell membrane and the cell wall.

peristalsis a wavelike sequence of involuntary muscular contraction and relaxation that passes along a tubelike structure, such as the intestine, impelling the contents onwards. —**peristaltic** *adj.*

peristaltic pump a pump that functions, by analogy with the action of **peristalsis**, by the repeated compression of a length of elastic tubing in such a way as to cause the contents of the tubing to move in one direction in a pulsating fashion but with an overall flow rate that is constant and regulated by the rate of pulsation and the tubing diameter.

peritoneum the thin translucent membrane, consisting of a single layer of flattened mesothelial cells and fibrous connective tissue,

that lines the abdominal cavity and covers most of the viscera. —**peritoneal** *adj.*; **peritoneally** *adv.*

PERK *abbr.* for perturbed folding-activated kinase; *other names*: pancreatic ER-stress kinase; eIF-2 kinase. A protein serine/threonine kinase of the endoplasmic reticulum (ER) membrane, found especially in pancreatic cells. Its luminal regulatory domain normally binds BiP (*see* **binding protein**), which inhibits the cytosolic catalytic domain. When unfolded proteins accumulate in the lumen (i.e. under ER stress), BiP is released and the catalytic domain is activated. One substrate is the initiation factor eIF-2, which on phosphorylation suppresses protein synthesis. PERK-deficient mice develop marked hyperglycemia soon after birth. Inactivating mutations in humans result in a form of diabetes mellitus type I, which is associated with multiple epiphyseal abnormalities, called Wolcott-Rallison syndrome.

Perl *see* **programming language**.

perlecan *another name for* **heparan sulfate proteoglycan core protein**. *See also* **syndecan**.

permeability 1 the quality or degree of being permeable or porous. **2** or **magnetic permeability** (of a substance) *symbol*: μ ; the ratio of the **magnetic induction**, B , to the magnetic field strength, H , at any point within the substance, i.e. $\mu = B/H$. The SI unit is the henry per metre or newton per square metre.

permeability coefficient a measure of the ability of a specified permeant to diffuse across a permeability barrier. It is expressed as the amount of substance of the permeant passing through a unit area of the barrier in a unit time when a unit difference in amount-of-substance concentration is applied across it.

permeability of vacuum *symbol*: μ_0 ; a fundamental physical constant, of value $4\pi \times 10^{-7} \text{ H m}^{-1}$ exactly.

permeability transition pore a pore believed to form at sites of contact between the inner and outer mitochondrial membranes. It probably consists of the voltage-dependent anion channel (VDAC) of the outer membrane, the adenine nucleotide translocator of the inner membrane, and cyclophilin D of the matrix. When open the channel is permeable to particles of <1500 Da. Its opening probably dissipates the H^+ gradient and uncouples oxidative phosphorylation.

permeabilize or **permeabilise** to render permeable. In cell biology, agents such as **saponin**, streptolysin O (*see* **streptolysin**), or an applied electric field are used to open holes in the plasma membrane of cells. —**permeabilization** or **permeabilisation** *n.*

permeable capable of being permeated; pervious.

permeant 1 able to permeate or to diffuse into or through. **2** a substance having such properties.

permease a historical designation of some specific transport proteins; **transporter** is preferable.

permeate to pass through, or cause to pass through, by diffusion; to pervade. —**permeation** *n.*

permeation chromatography any form of chromatography in which a permeable stationary phase is used and in which separation of the components of a mixture is based mainly upon selective exclusion effects, such as differences in molecular size and/or shape (in **molecular-sieve chromatography**) or differences in charge (in **ion-exclusion chromatography**). *See also* **gel-permeation chromatography**.

permissible allowable. —**permissibility** *n.*; **permissibly** *adv.*

permissive 1 allowing; tolerant. **2** (*in virology*) describing a line or strain of cells that allows replication of a specified infecting virus with consequent cell lysis. **3** (*in genetics*) describing a condition, e.g. temperature, or set of conditions that permits the growth of a conditional lethal mutant (*see* **conditional lethal mutation**). —**permissiveness** *n.*; **permissively** *adv.*

permissive temperature *see* **temperature-sensitive mutation**.

permittivity *see* **relative permittivity**.

permselective selectively permeable to certain (classes of) molecular entities.

permutation 1 the process or act of permuting. **2** any of the possible arrangements of the members of a specified set of conditions, numbers, residues, etc.

permute to change the sequence or arrangement of.

Permutit a *proprietary name* for ion-exchange materials and equipment utilizing **permutites**.

permutite any of a class of artificial zeolite ion-exchangers.

pernicious anemia or (*esp. Brit.*) **pernicious anaemia** a form of macrocytic anemia characterized by defective production of erythrocytes and the presence of megaloblasts in the bone marrow, and sometimes accompanied by neurological changes. It is caused by a deficiency of vitamin B₁₂ due to either a dietary deficiency of the vitamin or a failure of production of **intrinsic factor**.

per os *Latin* by mouth; used especially to denote the administration of drugs, etc. by the oral route.

peroxidase 1 any oxidoreductase enzyme of the sub-subclass EC 1.11.1. These act on hydrogen peroxide as (electron) acceptor with the formation of water. **2** *the recommended name of the enzyme* EC 1.11.1.7, a hemoprotein that catalyses the reaction of hydrogen peroxide with a wide variety of donors, i.e.

Apart from removing H₂O₂, it participates in the oxidation of toxic reductants and in lignin metabolism. In plants there are isoforms in different tissues. —**peroxidatic** *adj.*

peroxidase-antiperoxidase *abbr.*: PAP; a soluble complex of horseradish **peroxidase** (def. 2) and an antibody to this peroxidase, used in immunochemical procedures in conjunction with specific primary and bridging second antibodies to give a sensitive method of detecting complementary antigens enzymatically.

peroxide 1 (*in inorganic chemistry*) **a** the O₂²⁻ ion. **b** any member of a class of metallic oxides, such as sodium peroxide, Na₂O₂, that contain the peroxide ion and generate hydrogen peroxide on acidification. The name is sometimes used erroneously for certain higher oxides that do not contain the O₂²⁻ ion; e.g. lead peroxide (lead(IV) oxide, PbO₂), manganese peroxide (manganese(IV) oxide, MnO₂), nitrogen peroxide (nitrogen(IV) oxide, NO₂ or N₂O₄). **c** *short for hydrogen peroxide, H₂O₂; an oxidizing agent.* **2** (*in organic chemistry*) **a** any compound of general formula R'-O-O-R'', where the groups R' and R'' are two chains, two rings, or a ring and a chain, and including cases when R' = R''; e.g. ethyl phenyl peroxide, benzoyl (strictly, dibenzoyl) peroxide. In hydrogen peroxide, R' = R'' = H. **b** *see hydroperoxide.*

peroxin or **PEX protein** any protein in yeast or mammalian cells that mediates the import of peroxisomal integral membrane and matrix proteins and is necessary for peroxisome biogenesis. Fifteen PEX genes are known in humans. They encode receptors for the two peroxisome target signals, plus cytosolic and peroxisomal proteins. Mutations in several of the genes lead to **Zellweger's syndrome** and infantile **Refsum's disease**. *See peroxisome targeting sequence.*

peroxidoxin (*abbr.*: Prx) or **thioredoxin peroxidase** or **alkyl peroxide reductase** any member of an abundant and widespread family of antioxidant enzymes, capable of removing hydrogen peroxide and alkyl hydroperoxides from cells. The enzymes contain an active-site cysteine, which is oxidized by peroxide to a sulfenate, which is subsequently reduced by a thiol-containing protein such as thioredoxin.

peroxisomal bifunctional enzyme a monomeric peroxisomal enzyme (mainly in kidney and liver) with the activities of three steps in the **beta-oxidation system**, i.e. **enoyl-CoA hydratase**, **3,2-trans-enoyl-CoA isomerase**, and **3-hydroxyacyl-CoA dehydrogenase** activities.

peroxisomal disorder any disorder in which peroxisomes are absent or severely reduced in number, are incapable of importing a group of resident proteins, or lack a particular resident enzyme activity. Examples include **Zellweger's syndrome**, and adult and infantile forms of **Refsum's disease**.

peroxisome a type of eukaryotic cell organelle that is rich in enzymes that act on or generate hydrogen peroxide, especially the enzymes catalase, (S)-2-hydroxy-acid oxidase, and D-amino-acid oxidase. Peroxisomes occur in mammalian kidney and liver, and in yeasts and certain protozoans. They contain over 50 matrix enzymes involved in degradation of very-long-chain, branched, or polyunsaturated fatty acids, in the conversion of cholesterol to bile acids, and in biosynthesis of other phospholipids and isoprene compounds. They are particularly numerous in leaf photosynthetic cells of plants, photosynthesizing via the Calvin (C₃) pathway; in plants they are closely associated with chloroplasts and mitochondria,

which is consistent with their function in **photorespiration**. —**peroxisomal** *adj.*

peroxisome proliferator-activated receptor *see* PPAR.

peroxisome targeting sequence *abbr.*: PTS; either of two highly conserved peptide sequences that target proteins to the peroxisomal matrix. PTS1 is the C-terminal sequence -Ser-Lys-Leu. It is present in the majority of such proteins and is recognized by PEX5, which contains six or seven tetratricopeptide repeats in its C-terminal half. PTS2 is the N-terminal consensus sequence -Arg-Leu-Xaa₅-His-Leu-. It is present in a small minority and is recognized by PEX7, which contains six WD40 repeats. *See peroxin.*

peroxo+ *prefix (in inorganic chemical nomenclature)* indicating substitution (in the corresponding group) of an -OH group by the -O-OH group; e.g. peroxomonosulfuric acid, HO-SO₂-O-OH.

peroxoacid (*in inorganic chemistry*) any acid that contains the -O-OH group. *Compare peroxy acid.*

peroxonitrite *the recommended term for the anion of peroxyxynitrous acid, O=N-OO-*; a highly reactive oxidizing species formed by reaction of nitrogen monoxide (NO) with superoxide, or nitroxyl ion with O₂. It has been implicated in cellular damage resulting from the **respiratory burst**.

peroxy+ *prefix or infix (in carboxylic-acid nomenclature)* indicating substitution of the -OH group in the carboxyl group by the -O-OH group; e.g. peroxypropionic acid, CH₃-CH₂-CO-O-OH. *See also per+* (def. 2c).

peroxy acid (*in organic chemistry*) any acid that contains the -CO-O-OH group. *Compare peroxoacid.*

peroxyformic acid *see* performic acid.

peroxynitrite *see* peroxonitrite.

perpendicular dichroism *see* dichroic ratio.

persalt any salt of a **peroxoacid** or a **peroxy acid**.

perseitol D-glycero-D-galacto-heptitol; a substance found in avocado and the alligator pear.

persephin a secreted protein that is structurally related to **glial cell-derived neurotrophic factor** and neurturin and like these binds a specific GPI-anchored membrane protein that recruits and signals through **RET**.

perspective formula a type of **projection formula** in which the bonds of (a part of) a molecule tend to be depicted with increasing boldness according to their nearness to the viewpoint, and vice versa, in order to give an impression of perspective. *See Haworth representation, Mills perspective representation.*

Perspex a proprietary name for poly(methyl methacrylate).

pertactin *other name*: outer membrane protein P68; an agglutinin of *Bordetella* spp. that binds to eukaryotic cells, and is involved in the pathogenicity in whooping cough. It contains the **RGD** sequence motif.

perturb to cause a selective and measurable change in the state of equilibrium of a system, or in its associated properties, through the action or influence of a specific external agent; to undergo perturbation. —**perturbable** *adj.*

perturbant an agent (capable of) causing perturbation.

perturbation 1 the action or process of perturbing; an instance of this. **2** the condition of being perturbed. **3** a cause or factor of disturbance; perturbant.

pertussis toxin a toxic protein complex produced by *Bordetella pertussis*, the bacterium responsible for whooping cough in young children. The toxin causes inactivation of the **ia** subunit of the **G-protein** through catalysing ADP-ribosylation of a cysteine residue that is the NAD-dependent ADP ribosyltransferase (EC 2.4.2.-). The toxin consists of five proteins (S1-S5) organized in two functional subunits, A and B. Subunit A comprises S1, which has the enzymic activity, and irreversibly uncouples the GTP-binding proteins G₁₀ and **transducin** from their membrane receptors. Subunit B binds to the membrane receptors; it has the composition S2S3S5S4₂, dimers S2S4 and S3S4 being held together by S5.

pervaporate to vaporize a liquid from one side of a semipermeable membrane with which it is in contact on the other side, as a means of concentrating a solution or suspension in that liquid. —**pervaporation** *n.*

pervious permeable.

PEST hypothesis the hypothesis that the presence of one or more

regions rich in proline (P), glutamic acid (E), serine (S), and threonine (T) in the primary structure of a protein confers susceptibility to rapid intracellular proteolysis.

pesticide any substance, natural or artificial, used to kill pests.

PET *abbr.* for positron emission tomography; *see* **tomography**.

peta+ *symbol:* P; SI prefix denoting 10^{15} times.

PETG *abbr.* for polyethyleneterephthalate glycol; a plastic developed as an alternative to PVC for use in packaging; in contrast to PVC it does not produce chloride fumes when burned, giving off only CO_2 and H_2O . Flexible, clear, robust, and light, it is also suitable for contact with food, since no plasticizers or stabilizers are used in its manufacture.

petite 1 describing a strain of yeast (or other) cells derived from a spontaneous mutant in which certain respiratory enzymes are defective or deficient, with consequent very slow growth and formation of unusually small colonies. **2** describing such a colony or mutant.

Petri dish or **Petri plate** a shallow, flat-bottomed, circular dish, usually of glass or transparent plastic and 5–15 cm in diameter, with a loosely fitting, overlapping cover. It is used especially for plate cultures of bacteria and moulds on solid (gelled) media, and for tissue culture. [After Richard Julius Petri (1852–1921), German bacteriologist.]

petroselaidic acid *see* **octadecenoic acids**.

petroselenate *numerical symbol:* 18:1(6); *the trivial name for* Z-*octadec-6-enoate*; a component of the fatty-acid hydrolysate of umbelliferous seed oils.

petroselenic acid *see* **octadecenoic acids**.

pET vector a plasmid vector designed for the overexpression of cloned genes in *E. coli*. Expressed proteins are fused to a **His-tag** or other fusion partner incorporated to facilitate purification. Expression is under the control of the bacteriophage T7 promoter and is caused by inducing the T7 RNA polymerase in the host cell, often **BL21** (DE3), with **isopropyl β -thiogalactoside** (IPTG).

PEX5 *see* **peroxin**; **peroxisome targeting sequence**.

PEX7 *see* **peroxin**; **peroxisome targeting sequence**.

PEX protein *an alternative name for* **peroxin**.

pEX vector a plasmid vector designed for overexpression of cloned genes in *E. coli*. Sequences are cloned at the 3' end of **lacZ** and the product is a fusion protein with β -galactosidase at the N-terminus. Some proteins expressed in this way are less susceptible to intracellular proteolysis.

Peyer's patch any of numerous subepithelial aggregates of lymphoid tissue found in the intestinal mucosa. The M cells that overlie them transmit bacterial and viral protein antigens, which induce proliferation of the lymphoid cells and the secretory immune response. [After Johann Peyer (1653–1712), Swiss anatomist.]

Pfam *see* **pattern database**.

pFc' fragment a protein fragment obtained (together with **F(ab')₂ fragment**) by pepsin hydrolysis of an immunoglobulin molecule. That from human IgG is a 27 kDa protein, which is a non-covalently bonded dimer consisting of the C-terminal moieties of the heavy chains, and resembles the **Fc fragment** without the residues containing the linking disulfide bond.

PFGE *abbr.* for **pulsed field gel electrophoresis**.

PFP *abbr.* for pore-forming peptide or pore-forming protein; the term embraces cytotoxic peptides such as staphylococcal δ -toxin, **alamethicin**, **magainins**, and **cecropins**; pore-forming proteins include staphylococcal α -toxin, **streptolysin-O**, cnidarian toxins, **perforin**, and **aerolysin**.

PFK *abbr.* for phosphofructokinase.

pfu *abbr.* for plaque-forming unit; a measure of the abundance of viruses or bacteriophages based on their ability to form zones of infection (plaques) on a monolayer of host cells.

Pfu polymerase a thermostable DNA polymerase from *Pyrococcus furiosus* valued for its 3'→5' exonuclease activity that imparts a **proofreading** function. Transcripts produced with *Pfu* polymerase have a lower error rate than can be obtained with enzymes such as *Taq* polymerase, which lack 3'→5' exonuclease activity.

pg *symbol for* picogram (i.e. 10^{-12} gram).

pG *symbol for* titration pK.

PG *abbr.* for 1 phosphatidylglycerol. **2** prostaglandin. **3** protegrin.

PGA *abbr.* for **1** phosphoglyceric acid. **2** pteroylglutamic acid. **3** prostaglandin A; *see* **prostaglandin**.

PGAH₄ *abbr.* for tetrahydropteroylglutamic acid.

PGAM *abbr.* for phosphoglycerate mutase.

PGB *abbr.* for prostaglandin B; *see* **prostaglandin**.

PGD *abbr.* for **1** phosphogluconate dehydrogenase (EC 1.1.1.43). **2** prostaglandin D (*see* **prostaglandin**).

PGE *abbr.* for prostaglandin E; *see* **prostaglandin**.

pGEM vector a proprietary plasmid vector used for cloning polymerase chain reaction (PCR) products. Some DNA polymerases (such as *Taq* polymerase) add a single deoxyadenosine 5' phosphate to the 3' ends of amplified fragments and these can be ligated to the single 3' thymidine overhangs of the linear pGEM vector.

pGEX vector any of various proprietary plasmid vectors used for the expression of foreign proteins in *E. coli*. Genes of interest are cloned downstream, and in the same reading frame, from the gene for glutathione-S-transferase (GST), and the product is a fusion protein with GST at the N-terminus. The presence of GST facilitates purification of the fusion protein by affinity chromatography on columns of immobilized glutathione, and its immunodetection using anti-GST antisera. Immediately downstream from GST and upstream from the protein of interest is a short stretch of sequence containing a motif recognized by thrombin (factor Xa). Proteolytic digestion of the fusion protein cleaves the protein of interest from GST. Expression of GST fusion proteins is under the control of the *tac* promoter and is induced with **isopropyl β -thiogalactoside** (IPTG).

PGF *abbr.* for prostaglandin F; *see* **prostaglandin**.

PGF synthase *abbr.* for prostaglandin-F synthase.

PGG *abbr.* for prostaglandin G (*see* **prostaglandin**).

PGH *abbr.* for prostaglandin H (*see* **prostaglandin**).

PGH synthase *see* **prostaglandin-endoperoxide synthase**.

PGI *abbr.* for prostaglandin I (i.e. **prostacyclin**).

PGK *abbr.* for phosphoglycerate kinase.

pGL vector any of a number of proprietary plasmid vectors used for the analysis of promoter or enhancer function. The putative promoter is cloned upstream from the firefly luciferase gene, whose expression can be detected with great sensitivity if the promoter is active in mammalian cells transfected with the pGL construct.

P glycoprotein or **MDR protein 1** a glycoprotein associated with drug resistance; it is a transmembrane ATP-dependent transporter that pumps hydrophobic substances out of cells. Drug-resistant cells demonstrate increased expression of the P-glycoprotein gene as one mechanism for their resistance to, e.g., chemotherapeutic anticancer drugs. *See also* **MDR**.

PGT (*in clinical chemistry*) *abbr.* for phosphoglucomutase.

pH a dimensionless quantity notionally defined as the negative decadic logarithm of the molal activity of hydrogen ions in a solution. Since the activity of a single species of ion is not measurable, pH is defined operationally according to the equation:

$$\text{pH}(X) = \text{pH}(S) + (E_s - E_x)F/(RT \ln 10)$$

where pH(S) and pH(X) are the pH values of a standard solution, S, and of the test solution, X, respectively; *F* is the Faraday constant, *R* the gas constant, and *T* the thermodynamic temperature; and E_s and E_x are, respectively, the electromotive forces of the two galvanic cells:

reference electrode | KCl (conc.) || soln. S | $\text{H}_2(\text{g})$ | Pt,

and

reference electrode | KCl (conc.) || soln. X | $\text{H}_2(\text{g})$ | Pt,

both cells being at the same temperature, with identical reference electrodes and bridge solutions, KCl (aq, $m \geq 3.5 \text{ mol kg}^{-1}$). A **pH standard** solution, S, is chosen from a set of five covering the range pH 3.5 to pH 9, an assigned value of pH(S) at the required temperature being obtained from published tables. To a good approximation, the hydrogen electrodes in the two cells may be replaced by other hydrogen-ion-responsive electrodes, such as glass or quinhydrone electrodes. Originally pH was considered as the negative decadic logarithm of the molar concentration of hydrogen ions, a practice retained to the present day as representing a convenient approximation.

pH* *a notation commonly used to denote the apparent pH of a solu-*

tion containing $^2\text{H}_2\text{O}$ (i.e. D_2O), as measured electrometrically using a glass electrode without correction for the isotope effect on the electrode.

Ph *symbol for the phenyl group.*

PH-30 or **PH30** a sperm surface protein, with **disintegrin** and metalloprotease domains; that from *Cavia cobaya* consists of two subunits, α and β .

PHA *abbr. for phytohemagglutinin (def. 1).*

pH-activity profile or **pH profile** a plot of enzyme activity against pH, over a range in which the activity is reversibly affected by pH.

pheo+ *an alternative spelling (esp. Brit.) of pheo+.*

phaeochromocytoma *an alternative spelling (esp. Brit.) of pheochromocytoma.*

phaeofarnesin *an alternative spelling (esp. Brit.) of pheofarnesin.*

phaemelanin *an alternative spelling (esp. Brit.) of pheomelanin.*

phaeophorbide *an alternative spelling (esp. Brit.) of pheophorbide.*

phaeophytin *an alternative spelling (esp. Brit.) of pheophytin.*

phage *abbr. for bacteriophage.*

phage conversion *an alternative name for bacteriophage conversion.*

phage display library a special example of a gene library encoding fusion proteins of a foreign polypeptide sequence and a coat protein of phage M13 or (more usually) the closely related phage fd. When cloned, the phage is then said to display the foreign protein (in the coat proteins). There are two common versions of the technique. In one, the library consists of random oligonucleotides (e.g. 7-mers). Clones expressing oligopeptides that react with a specific antibody can then be selected using the antibody. In the other version, the library consists of oligonucleotides encoding a range of single-chain variable-domain antibodies. This approach is used where an antibody is required for an oligopeptide, which can thus be used to detect appropriate clones.

phage immunity the immunity conferred on a **lysogenic bacterium** by the presence of a **prophage** and a consequence of the expression of a gene such as *cI* in **lambda phage**.

phage induction or **prophage induction** the stimulation of prophage in lysogenic bacteria to enter the vegetative state. It is accomplished by the action of UV light, X-rays, nitrogen mustards, etc.

phage lambda *see lambda phage.*

phagemid a chimeric phage-plasmid **cloning vector** containing origins of both double-stranded and single-stranded replication. *See also phasmid.*

phage T4 an icosahedral DNA-containing **bacteriophage** that infects *Escherichia coli*. Its single molecule of double-stranded DNA is 174 kb in length. Various enzymes prepared from this phage are commonly used in genetic engineering; these include ligase, polymerase, and polynucleotide kinase.

phage typing a procedure for classifying bacteria according to their susceptibility to various bacteriophages.

phagocyte any cell that characteristically engulfs particles from its surroundings into its cytoplasm by **phagocytosis**. —**phagocytic** *adj.*

phagocyte NADPH oxidase *abbr.:* phox; a phagosomal and plasma membrane complex that transfers electrons from NADPH, via FAD and heme, to O_2 to produce superoxide (O_2^-) and other microbicidal reactive species. The process constitutes the **respiratory burst**. The complex assembles and becomes active when phagocytes are activated in response to inflammatory stimuli. It consists of membrane components (gp91-phox and p22-phox, together called **cytochrome b_{245}**) and cytosolic components (p47-phox, p67-phox, and a Ras-related GTPase). Deficiency or dysfunction of any of the four phox proteins causes chronic granulomatous disease. Examples: human p47-phox, 390 amino acids; p67-phox, 526 amino acids.

phagocytosis a type of endocytosis whereby certain cells – phagocytes – can engulf external particulate material by extension and fusion of pseudopods around each particle. The particles are initially contained within phagocytic vacuoles (**phagosomes**), which then fuse with primary lysosomes to effect digestion of the particles. Phagocytosis is employed by certain cells of the immune system, notably macrophages and neutrophils, to engulf and destroy target cells, tissue debris, and other particles, and by amoeboid protozoans. *Compare pinocytosis.*

phagolysosome an organelle formed by the fusion of a **phagosome** and a **lysosome**. Immediately after fusion there is a brief rise in the pH of the phagolysosome and neutral proteases and cationic proteins are active. Subsequently the pH falls and acid proteases become active. Indigestible substances remain in the phagolysosomes forming residual bodies.

phagosome an inclusion in a eukaryotic cell that arises from the ingestion of particulate material by **phagocytosis**. The phagosomes subsequently fuse with **lysosomes** to form a **phagolysosome**.

phalloidin *see phallotoxin.*

phallotoxin any bicyclic heptapeptide present in the highly poisonous agaric fungus, *Amanita phalloides*, commonly called the death-cap fungus or deadly agaric, and in some related species; **phalloidin** is the best-known member. All phallotoxins but one are toxic, though not as intensely so as the congeneric and much more slowly acting **amatoxins**; high doses of phalloidin in mice or rats cause death in a few hours. The common elements include residues of *cis*-4-hydroxy-L-proline, a D-amino acid (which is either threonine or β -hydroxyaspartic acid), and L-tryptathionine (which forms a thioether bridge across the molecule). The majority of phallotoxins bind specifically to F actin and so prevent its depolymerization to G actin, thereby blocking the turnover of microfilaments and inhibiting cell movement.

phane nomenclature a method for naming organic structures by assembling names that describe component parts of a complex structure. A relatively simple skeleton for a parent hydride structure is modified by ‘amplification’, a process that replaces one or more special atoms (superatoms) of the simplified skeleton by multiatomic structure(s).

phantom indel a spurious insertion or deletion that arises when physical irregularities in a sequencing gel cause the reading software either to call a base too soon, or to miss a base altogether.

pharmaceutic *an alternative name for pharmaceutical (def. 2).*

pharmaceutical 1 of, or pertaining to, drugs or pharmacy. **2** or **pharmaceutic** any medicinal substance, mixture, or formulation. —**pharmaceutically** *adv.*

pharmaceutics *an alternative name for pharmacy (def. 1).*

pharmac+ *comb. form* indicating a drug or drugs.

pharmacodynamics *functioning as sing.* the branch of pharmacology dealing with the effects of drugs on the body, i.e. with the physiological, therapeutic, and toxicological responses to drugs with particular regard to the extent and time course of such effects. —**pharmacodynamic** *adj.*; **pharmacodynamically** *adv.*

pharmacogenetics *functioning as sing.* the branch of pharmacology dealing with the genetic mechanisms underlying individual differences in responses to drugs. —**pharmacogenetic** *adj.*; **pharmacogenetically** *adv.*

pharmacogenomics the analysis of drug responses with respect to genomic information (e.g. polymorphisms), aiming to customize therapies and reduce adverse drug reactions.
